Another serious development is the rapidly increasing loss of life and growing death rate, due largely to the excessive use of powder, especially where the practice of "shooting off the solid" prevails and where "blown out or windy shots" are liable to occur as a result of such proffligate use of powder. According to the 1910 Coal Report for Illinois, shooting off the solid is practiced in 57.7% of the mines. The number of men killed in 1910 was 406, including the victims at the Cherry mine.

Effect On Operators

Thus far, I have tried to show the effects of the gross-ton system upon the miners; but upon the operators they are certainly not less complex. In the first place, the quantity of slack coal produced is constantly increasing with the increased use of powder. There is not absolute agreement in the reports, in this regard, but some claim that in many of the mines in the central part of the coal field one-half of the coal mined is slack, which, of course, brings a low price and lowers the value of the total output. The profit operators make in selling powder to the miners does not compensate for the loss occasioned by the large percentage of screenings produced.

The principles of conservation are being violated in this waste. At a time when, at last, thinking people are alive to the duty of the preservation of natural resources, coal owners are forced to see much of their property sacrificed by the reckless methods of mining, which are legalized by special act and which, if continued, will lower the standard of mining and drive the better class of miners to seek employment elsewhere.

Again, heavy losses are sustained when, owing to explosion or other accident, or the overproduction of coal, or strikes, the mines are closed and the equipment injured or destroyed. New mines opened in 1902, when the long strike in the anthracite field afforded a new market to Illinois coal, have further complicated the situation for operators who were already in the field. I judge that many of the operators are ready to say that, if competition is the life of trade, competition may also prove to be its death.

But heavily as these burdens rest upon the operators, they feel most keenly and regret most deeply the loss of life and limb that overtakes the miners themselves and the sorrows and suffering that enter their homes, by reason of the oft-recurring accidents. However easy it may be to prove that injury or death was due to the carelessness or ignorance of the men themselves, operators are not blind to the fact that, under the circumstances, a measure of responsibility, large or small, and moral if not financial, falls upon them and compels them to do all in their power to insure the health and safety of the men.

Though legislation has slightly alleviated the situation in its attempt to control the use of powder by the shot-firing act, I judge the general situation in the state is steadily growing more acute, and Illinois operators and miners must get together on a more sound basis of equalization than the system now in use. If the newly organized Federation of Coal Operators will stand firmly and effectively together, a wiser and better system of paying miners may be thought out and adopted, and brotherly feeling between operator and miner strengthened thereby. The organization will thus certainly accomplish a much-needed work.

Type of Steel Tipple Construction Common at Illinois Mines

Possible Power Economies

By Henry D. Jackson *

Advocates the use of unsalable coal for colliery purposes. Central power stations tend to keep the coal demanded down to the capacity of the waste pile.

In your foreword of Jan. 6, I note your reference to the complaint of the coal operators that prices are low and general conditions unsatisfactory, particularly as a result of the increase in wages, the increase in cost of timber and other materials and the low price received for the product.

As you state, these increases require that the operator do something to offset them or that he effect every economy possible in the operation of his plant. Under the conditions resulting from the vast number of coal operations which are being started up, the only cure is economy in the production of coal.

Possible Economies

Economy can be obtained in a number of ways:

1. Economy can be secured by an increase in the amount of coal cut by such cutters as are already installed. This can be effected by operating these cutters at their maximum productive speed at all times, thus increasing the amount of coal which is undermined by each cutter, with consequent decrease of the cutting cost. This result only can be secured in the case of electrically operated machines by maintaining full voltage at the cutters, which in turn can generally be made possible by the proper distribution of the transmission lines and the use of the required amount of copper.

2. Decreased cost can be secured by increasing the capacity of the haulage, that is to say by making each locomotive handle its full capacity of cars. This in turn can usually be secured by giving them full voltage at all times. Hence the need for a proper design of the feeder system.

3. A third method of decreasing the cost is by increasing the efficiency of the power plant. At the present time there are a large number of mines operating stations of low efficiency and transmitting their power over feeder lines which are highly inefficient. This results in the use of a considerable amount of coal per year, which might otherwise be sold.

Economies by use of Waste Coal

One method of decreasing the cost of power at the plants might be by using the waste pile. To be sure, under most conditions this pile is composed of impurities in addition to the coal, and these are hard on the grates and cause considerable trouble; yet since this coal is entirely a waste product, the chances are that with a proper adaptation of grates and a proper handling of the fuel, there might result a considerable saving for then all the coal of good quality could be shipped to market and only the waste pile used. A conservative estimate will show that the type of plant usually installed for a small operation uses not less than 6 lb. of coal for each kilowatt hour.

If we take such a plant demanding 200 kw. continuously, the coal used would be 1200 lb. per hour, or 12,000 lb. per day of ten hours. This would represent a total coal consumption of 3,300,000 lb. per year of 275 days. If this coal were sold at a price of 90c. a long ton, it would show a saving of $1,325.70. Owing, however, to the fact that waste coal would probably cost a little more for handling and that the repair of the grates would be a further disadvantage, we might allow a reduction in price of 20c. per ton to cover this expense, so that the net saving would be 70c. per ton. This would reduce the economy to $1,031.10 a year. This, while small, is an important saving in a plant of this size and would pay interest charges at 6% on an investment of $17,185.00.

The use of a large plant supplying power to a number of operations would also materially reduce the costs. The investment for a mine power plant of good construction with three substations using rotary converters and supplying current to three operations, would be practically the same as the investment for three independent operations of fair quality and the same capacity. The coal required by a central plant will probably be half that required by three equivalent units, owing to the fact that the engine in the central plant is larger and also of somewhat better type, than the engine of a disconnected unit and further to the fact that its location will permit it to be more economically handled. In developing the same power that would be represented by three independent plants, the coal per kilowatt hour would be in the neighborhood of 4 lb. This figure allows for all the line and transformer losses so that a consumption of 4 lb. of coal may be expected to result in one kilowatt hour delivered at the substation. The estimate is based upon the supposition that coal of fair quality is used in the generating station and that the engines are operated with condensers. If each substation demands 200 k.w. the total coal required for ten hours a day, 275 days in the year, would represent approximately 2946 long tons, or a saving of $2,062.20, if waste coal is used in place of that which would be shipped.

Economy of a Central Plant

If now, in addition to this, we assume that we have saved by the use of the large plant the difference between the coal which would be burned in three small plants and that which will be burned in a large plant, there will be an additional saving of 2 lb. per kilowatt hour or 1473 tons. At 70c. per ton this will save $1031.10. Substation operations do not require the whole time of the attendant as this work can in most cases be done by a day man whose general duties require him to remain at or near the location of the substation. Consequently no charge need be made for attendants. This will cause a further saving of approximately $2288 per year, represented by the difference in wages which would have to be paid for a fireman and engineer in each plant, and the compensation which will now be paid to but one engineer and two firemen in the one big plant. These savings, if capitalized, will represent the interest on $89,688.33.

In addition to this, there is always the possibility of an even greater saving resulting from the use of electrically driven fans conveniently located and operated by alternating current. This saving will be large in many cases, as the change in installation will do away with the use of steam driven fan engines with their attendant high initial and operating cost. The coal required to furnish steam for these fans is excessive, as the engines are rarely economical, and steam has to be transmitted long distances. The actual saving is difficult to estimate, but it will probably be equivalent to the shutting down of one mining operation of 200 k.w. capacity for each 100-hp. used by the fans representing a saving of approximately $1,000 per year if coal from the waste pile could be used in the place of coal which would be shipped. The saving in initial cost, and, therefore, in interest and depreciation charges would be great, because the fan could be located most advantageously with regard to the mine workings, and little or no attention paid to the necessity for getting power to it, as high tension wires can be run practically anywhere.

*Consulting engineer with Sprague, Keyes & Jackson, 88 Broad St., Boston, Mass.

The Engineer on Development Work

By C. P. Collins *

Some pertinent and helpful hints for the young engineer together with a few notes on the magnetic meridian not generally known and an original chart for computing the per cent. grade at any angle of dip. Also a few timely observations on the preliminary investigations for a proposed mine.

*Civil and mining engineer, Johnstown Trust Building, Johnstown, Penn.

The art of surveying, which treats of making such measurements as will determine the relative positions of any points of the earth's surface, is of doubtful origin. It is the outgrowth of the science of geometry, which is derived from the Greek word *geometria*, meaning the "measurement of land."

Some attribute the invention of the art to the Egyptians, and that it was first practically applied by them in their efforts to recover and fix the land marks annually swept away by the inundations of the River Nile. The builders of the pyramids must have had some knowledge of the science of geometry. A papyrus in the British museum written 1700 years, B. C. gives rules for calculating the area of triangles and circles. The work of Hero of Alexandria 285, B C. mentions mine surveying and the crude instruments used at that time.

The Greeks surpassed all ancient nations in their attainments in the science of mathematics. Euclid founded a school of mathematics at Alexandria in Egypt during the reign of Ptolemy, B. C. 323 to 284. His elements are still in use in many schools and colleges; in fact, all textbooks on geometry are built upon the foundation so firmly and systematically laid in that early day by Euclid.

The Subdivisons

The art of surveying is wide in scope and extends from the measuring of a farm to that of the heavens. The principal branches are:

(1) *Land surveying,* which treats of the application of the principles of geometry and trigonometry to the measurement of land.

(2) *Geodetic surveying,* which includes all the operations of surveying, taking into consideration the curvature of the earth's surface; it is employed by the Government in compiling their maps and charts. While we use plane trigonometry in land surveying we must employ spherical trigonometry in geodetic surveying.

(3) *Hydrographical surveying*, which includes the locating of coast lines, harbor lines and channels, and embraces all operations necessary to a complete determination of the contour of the bottom of a harbor or other body of water.

(4) *Railroad surveying,* which is a comprehensive term, embracing surveys intended to ascertain the best line of communication between two given points; it also includes all surveys for the construction of bridges, viaducts, tunnels, etc.

(5) *Topographical surveying,* embracing all the operations incidental to finding the contour of a portion of land and locating all the objects which are worthy of note, and which are represented on the topographical maps by a system of conventional signs.

(6) *Mine surveying,* which includes the location of all important improvements, outcrops of minerals, and the outside boundaries of the mining operations, together with a careful location of all underground workings, and the preparation of maps showing the relative location of all points in the mine with the outside features.

Leveling, or vertical surveying, consists in determining the difference of elevation between given points, whereas, the location of the position of these points is horizontal surveying. In horizontal surveying the principal instruments required are the transit, plane table and tape and where great accuracy is not required, the compass. In vertical surveying we use the Wye level. The aneroid barometer is a useful instrument to determine the relative difference in elevations and when properly used gives fair results.

Necessity of Adequate Maps

If an experienced mining man be asked the essentials for the successful operation of a coal mine he would, no doubt, include ample ventilation, good drainage and favorable grades.

The all important features then for the mining engineer to determine are the facts which shall enable him to so lay out the mine that the ventilation may be ample to dilute the gases arising from the coal and replace the vitiated atmosphere by good, wholesome air. He must also drive his headings so the water may be successfully and economically removed, effecting drainage by gravity whenever possible, and if pumping be required, to so arrange his system of drainage that the water may be brought by gravity to a central point, from whence it may be removed by pumping.

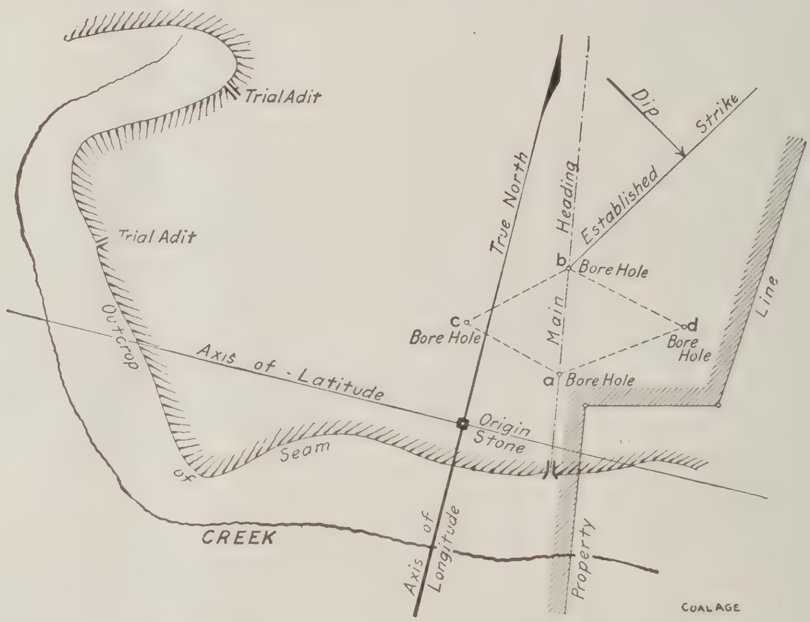

Fig. 1. Method of Prospecting a Virgin Field

Finally, and one of the most important features to bring the cost of output to a minimum, is a systematical plan of grades, that they do not exceed the limit for economical hauling of the coal from the workings to the tipple.

In order to effectually anticipate these requirements the engineer must, of course, make a careful survey of the field in question. Let us consider, for example, a virgin field of coal. The engineer must determine:

(1) The most feasible route for a railroad to enter the field.

(2) The extent and character of the coal to be won.

(3) The plane of the coal which will fix the line of strike and maximum dip of the seam.

(4) Whether the field be traversed by a synclinal or anticlinal axis.

Defining the terms just mentioned: The strike of a seam of coal is the line formed by the intersection of the seam with a horizontal plane, and is in Pennsylvania, Maryland and West Virginia, when normal conditions prevail, usually about North 30° East. The line of maximum dip is at right angles to the line of strike. The syncline corresponds to the valleys in the seam, and the anticlines to the ridges.

Establishing the Meridian

All surveys relating to the mining field proper, both inside and outside, should be carefully tied to a fixed base line. It has been my practice in all work of any importance, to carefully lay out a true

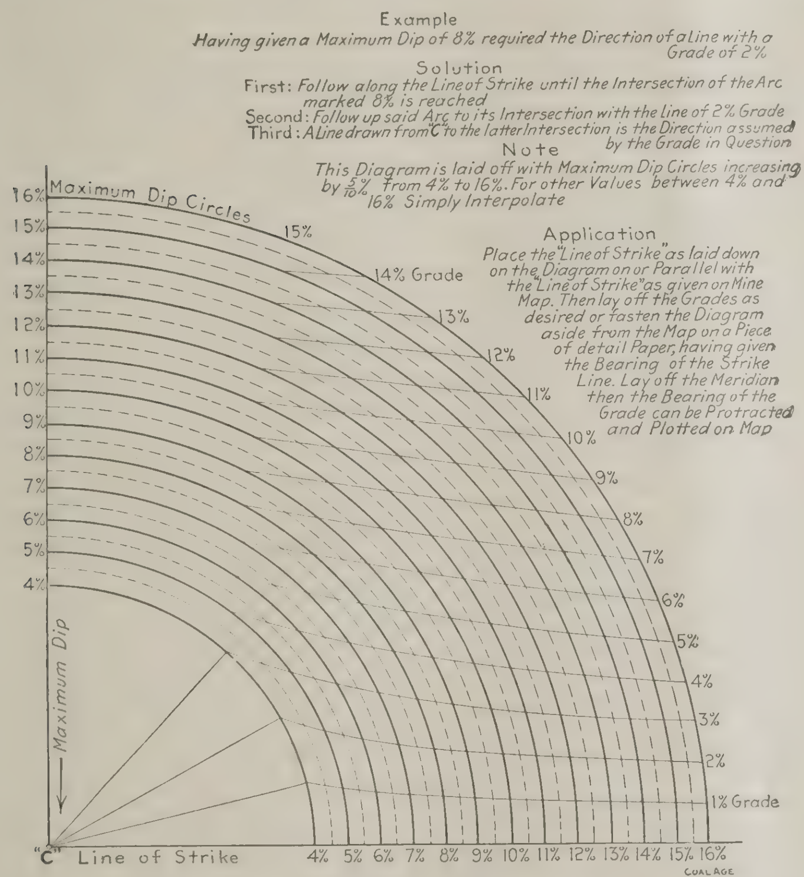

Fig. 2. Diagram for Computing the Grade at Any Angle to the Dip

meridian line from which to refer all future work.

The true meridian can easily be fixed by observations on the north star, known to astronomers as Polaris, which at certain intervals coincides exactly with the polar axis of the earth and is then said to be "on the meridian." *

It is slightly removed from the pole, and in our latitude corresponds to about 1½°. It appears to be gradually approaching the pole and from 1885 to 1906, a period of 21 years, its azimuth has decreased 0° 8′ 36″. Polaris can easily be found in the Northern heavens by first finding the well known circumpolar constellation, commonly known as the "Big Dipper," but to astronomers as Ursa Major or "Great Bear." It consists of 7 stars, as per Fig. 3, and the two outer stars of the bowl of the Dipper, known as the "Pointers," point very nearly to the North Star, thus assisting in finding it. The North Star is in the constellation Ursa Minor or "Little Bear," commonly called the "Little Dipper," and is the last star in the handle.

The Magnetic Meridian

The magnetic meridian, or the direction of the magnetic needle is constantly changing, and it may be of interest to say a few words concerning this strange phenomenon.

It appears to swing slowly like a gigantic pendulum. The most ancient observations are those taken in Paris: In the year 1541 the needle pointed 7° east of north; in 1580, the declination had increased to 11½° east, being its maximum; the needle then began to move westward, and in 1666, it had returned to the meridian; the declination then became west and continued to increase, till in 1814, it attained its maximum, being 22° 34′ west of north. It is now decreasing and in 1879 was 16° 56′ west.

Reviewing the experiments at Paris, we find the needle swung for a period of 39 years at the rate of about 7 minutes per year; it then began to swing backward towards the west, and in 86 years returned to the meridian, the movement being at the rate of a little over 8 minutes per year; it continued to swing to the west for 148 years at the rate of a little over 9 minutes per year when it again began to swing backward, the complete circle being covered in 234 years, at the rate of a little less than 8¾ minutes per year.

In this country the north end of the needle was moving eastward at the earliest recorded observation, and continued to do so until about the year 1815, when it began to swing westward and has ever since continued in that direction. Here, at Johnstown, the variations are at the present time about 4° 48′ west of north, and has been moving westward at the rate of about 3 minutes per year.

The needle also has a diurnal variation or daily change. In the northern hemisphere the south end moves westward from 8 a.m. to 1:30 p.m. over an arc of 5 to 15 minutes and then gradually returns to its former position. It crosses the mean magnetic meridian at 10:30 a.m. The diurnal variations change with the seasons, being greater in summer than in winter.

Through all places where the needle points to the true north, a line has been traced, called the "Line of No Variation." In the United States this line in 1900 passed a little east of Columbia, S. C., just west of Charlestown, W. Va., near Lansing, Mich., and enters the Dominion of Canada near the eastern shores of Lake Superior; this line is slowly moving westward. At all points East of this line the needle points west of north and at all points West of this line the needle points east of north. The cause of the movement of the magnetic needle is unknown, and because of the fluctuating value of the magnetic meridian it is of great importance to refer all our azimuths or angles to the true north.

The Zero of Co-ordinates

It is well to establish a good stone monument in close proximity to the mouth of the mine, calling this the zero of latitude and longitude for all future work. This stone is the origin or initial point of survey. At a convenient point and as far away as possible, another stone should be carefully set on the true meridian line; this stone is known as the "Sight Stone" for pointing the transit on the correct meridian.

Having thus established a good, reliable base, there is no excuse for inaccurate work and the position of all points

---

*For a convenient graphic method of determining the true meridian by an observation on Polaris at any hour, the reader is referred to Coal Age, Vol. 1, p. 245.

must be determined by their mutual relationship with the original stone and meridian line. Thus the location of any point must be so many feet east or west of the established meridian, and so many feet north or south of the original stone. These notations are known as the coördinates of that point, and the point itself as the zero of coördinates.

It is of great importance that the engineer have on file in his office a book of coördinates for each mine under his care and have recorded therein a record of all property lines and other outside points of interest, also the mouth of the mine and all the important points in each and every heading in the mine itself. It is thus a simple calculation to determine the direction required for connecting certain points in the mine and in what direction a given heading must be driven to "just pass" a corner of an adjoining property, and not trespass thereon.

Prospecting and Drilling

Having thus established a reliable base line the outcrop can be located, and at favorable places small drifts driven into the coal far enough to disclose the seam in its natural bed. Levels are then taken at each of these points and from these data we calculate the plane of the coal. Having obtained in this way an approximate idea as to the general character of the coal seam, we lay out on a plotted map of the property, a proposed location for the entrance of the mine and also the direction of the main heading. This is known as the preliminary location.

Our next step then will be to prove whether or not our results obtained from the outcrop conditions, hold good in the body of the field, and also if the coal still retains a workable thickness. To obtain this very necessary information, the engineer should obtain the services of an honest and careful driller to put down such holes as he may direct.

The only proper drill for the work is the diamond drill of, at least, 2¼ in. core, and great care should be exercised that the driller sinks all holes in a truly vertical line, which can be done if he carefully levels up the machine before starting. The necessity of this is self-evident.*

The holes are usually put down on the line of the proposed main heading and one on each side of the main heading, as shown in Fig. 1.

Computing the Dip and Strike

We will then have two sets of triangles, *abc* and *abd* from which to calculate the plane of the coal. The first hole on the line of the proposed main heading should be at least 1500 ft. from the pit mouth and the sides of the triangles *abc* and *abd* should be about 1500 ft. in length.

After these holes are finished, they should be carefully cased to the rock and plugged with a white pine plug, the center of each being fixed by a tack. Each hole will then be carefully located in respect to the origin stone already mentioned, and they will serve as excellent checks for further underground surveys. Levels are also carefully taken on the tops of these plugs, and having given the depth of the holes, we can easily obtain the level of the seam below.

Four holes is the least number that can be put down to effectually test the body of the field; another set of triangles would, if the field be large, greatly decrease the liability of error in making future projections for the underground workings. If the results of the drilling are favorable, as to the physical and chemical qualities of the coal, and if they show the seam to be of a workable thickness, the engineer can then make his

Fig. 3. Northern Polar Constellation

final location and do it with the feeling that he has not opened the mine in the wrong place. The line of strike and maximum dip having now been determined, it is an easy matter to project the headings on feasible grades. The grade diagram shown in Fig. 2, I have used to good advantage in this work.

No matter how favorable a seam of coal may appear at the outcrop, it is a part of wisdom to resort to drilling and thus test the body of the field from which the good coal must be won. I have known many instances where the coal appeared to be in excellent condition at the outcrop, and utterly failed as a mining proposition; but this was only found out after thousands of dollars had been spent in installing a modern plant. How many times one hears it said: "Why, that mine is opened in the wrong place."

Results of Insufficient Engineering

The mine has been started; they find now by actual working what should have been pointed out to them by a competent engineeer. They try to drive a heading in this direction and find it is going to the dip; they turn, and it is too flat; they turn again and it is too heavy a grade, and soon have a mine which is simply a hole in the ground, utterly devoid of any system whatever.

Now they find they are not able to keep up the output, and tne superintendent gets a letter from the New York office which makes his ears sing. The mine was located near an anticlinal axis, the main heading is beginning to rise at an abnormal grade, the coal begins to show signs of breaks and faults, and soon begins to descend into another basin, all of which is found out when contracts are to be filled and coal at a top notch price.

Yes, this is a familiar picture to all who are concerned with mining. There is no necessity for guessing; this method of trying to drive this way and that to obtain favorable grades is wholly uncalled for; mining is becoming more and more each day a scientific study, and will continue so until in the near future as much care will be exercised in the location of a mine as is now paid to the location of a railroad, and as much stress will be put on their proper layout as that of a town, which shall one day develop into a large city.

A mine is, in fact, an *underground town*, where ventilation, drainage and feasible grades are the universal requirements for future success, all of which depends so much upon the consideration and accurate preliminary work of the Mining Engineer.

Mine Car Lubrication

Perfect lubrication contributes enormously to the reduction of expense for wear and tear on any machine, but it would seem that its benefits in connection with mine-car equipment have never been fully realized or even approximately attained. The lubrication of mine-car wheels is a subject that, apparently, has not been given the serious thought and consideration that it deserves on the part of car-wheel manufacturers or mine operators.

Probably the most widely used form of wheel for mine service is that known as the cavity type. This is an ingenious device, but one which has never satisfactorily proved its value on account of the great number of poor lubricants that are easily available and generally used. Oil, of one kind or another, is usually supplied to these wheels, but, as a matter of fact, oil is not a properly constituted lubricant for this class of work. While the cavity mine-car wheel may have originally been designed for the use of oil, the idea has never worked as satisfactorily in practice as in theory. There is, as a rule, too much clearance and lost motion between the axle, wheel and other parts, to secure an economical use of oil.

It is probably no exaggeration to say that at least 50 times more oil is wasted than is actually consumed in mine-car service, so that under these conditions a

*For additional notes on prospecting with drills, the reader is referred to "The Lignite Fields of Colorado" in Coal Age, Vol. 1, p. 535. The irregular character of the Cretaceous coals of the West has probably made the Western engineer more efficient in this respect than his Eastern brethren.—Editor.

high-grade oil develops no greater economy than a cheap oil, and its fluidity causes it to waste away quite as freely, irrespective of its lubricating value. It would therefore seem that the user derives as much benefit from the cheapest grade of black oil as from the better and more expensive varieties.

Requirements for a Lubricant

A heavy grease is, perhaps, even more inappropriate than a thin oil for use in the cavity-type mine-car wheels, on account of its solidity. The axle receives its supply of lubrication through a slot or opening, which leads from the reservoir cavity in the hub of the wheel. The lubricant should be of a proper consistency to leak through these openings when the car is at rest, but if it is too fluid and does not possess the proper body or viscosity, it will work out rapidly when the wheel is in motion, leaving the axle and wheel dry, and subject to friction that increases in proportion to the load on the car.

With these conditions in mind, the Keystone Lubricating Co., of Philadelphia, has developed a lubricant which is especially adapted for use in mine-car wheels of the cavity type, although it can also be used satisfactorily in other forms of wheels, such as those fitted with roller bearings, etc. This material is known as No. 119 mine-car grease, and is said to possess the exact semi-fluid consistency, or viscosity, necessary to feed properly through the small opening from the reservoir cavity of the wheel to the axle, when the cars are at rest.

The grease is not soluble in water, and it is claimed that a metal surface coated with this material is rendered immune from the chemical attack of even the strongest mine water. The lubricant is in itself neither alkaline nor acid, and consequently has no harmful action on the metal which it coats.

Plugs for Oil Cavities

Many makes of mine wheels are not equipped with plugs in the feed holes leading to their oil cavities, but to obtain economical service with the Keystone compound it is imperative that the wheels should be tapped and plugged before the lubricant is applied, as it cannot be expected to give satisfactory service if afforded so easy an opportunity of wasting. It has frequently been considered unnecessary or undesirable to tap and plug these holes when oil was employed, because the bother of unscrewing and replacing the plugs recurred too frequently to warrant the effort for economy. But when it is necessary to apply the lubricant only at periods of from three to six months apart, the labor and time lost in connection with handling the plugs becomes inconsiderable.

Tests of Lubricant

This lubricant has been subjected to tests in the laboratories of the William Cramp & Sons Ship & Engine Building Co., of Philadelphia, under the direction of M. H. Schwenk, engineer of tests, and also in the laboratories of Cornell University, under the direction of Prof. R. C. Carpenter, and in every instance is reported to have developed a lower frictional resistance than any of the other lubricants tested in comparison.

One of the chief merits claimed for this material is the fact that its consistency does not change under extreme conditions of heat and cold. During January of this year, the unusually cold weather which prevailed throughout the country afforded a severe test for this quality of the grease. At Hazleton, Penn., and at Danville, Ill., the temperature frequently reached as low as 15 to 20 deg. below zero. This lubricant was in use at both the towns mentioned, and is said to have developed the same lubricating efficiency at these temperatures as it did when more moderate weather prevailed.

The Blakely Manufacturing Co., of Duquoin, Ill., reports having made a test on No. 119 grease, the details of which are as follows: On Jan. 2, 1912, they placed 2½ lb. of the lubricant in one of their 16-in. car wheels, weighing 100 lb., mounted it on an axle, and connected it, by means of a belt, to a line shaft. From Jan. 3 to 31, the wheel ran 212½ hours at 120 r.p.m., which is equivalent to traveling a total distance of 1213.47 miles on a track. The wheel had a 2⅛-in. diam. bore.

On Jan. 31, the wheel was removed from the shaft, cleaned of surplus grease, and was found to weigh ½ lb. less than when started on the test. This ½ lb. of grease had in part been lost along the axle, and also represented that which dripped from the oil holes while the wheel was standing or running. No attention was paid to the position in which the oil holes happened to be when the wheel came to rest, and it was allowed to remain just as it stopped. With the exception of several days, during which it was run for 5 hours only, the wheel ran 9½ hours each day. It was run continuously for 5¼ hours every morning, and for 4¼ hours every afternoon.

The British Coal Fields

Special Correspondence

At the present time when labor problems in the British coal trade are so much in evidence, the accompanying chart of the coal fields of England, with the accompanying statistics, are of interest.

Map of English Coal Fields, Showing Railroad Connections to London

District	Annual Output	No. of Miners	Miles to London
Scotland	41,500,000	55,000	380
Northumberland	12,600,000	46,000	275
Durham	39,400,000	128,000	245
Cumberland.	2,175,000	7,000	310
North Wales	3,500,000	11,200	185
Lancashire..	23,750,000	57,000	198
Yorkshire...	38,500,000	93,500	175
Derbyshire..	7,250,000	47,000	130
Nottingham.	13,850,000	37,000	...
Staffordshire	14,000,000	29,000	146
Worcester ..	6,000,000	11,000	115
South Wales ...	48,750,000	120,000	180
Gloucester & Somerset .	1,500,000	7,600	120

The estimated coal resources of the British Isles have been proved at 100,000,000,000 tons. The average annual world's production is 1,070,000,000 tons, of which the United Kingdom's proportion is 263,000,000 tons, and of this total 84,500,000 tons were exported.

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Ignition of Gas by Roof Falls

Joseph G. S. Hudson, mining engineer of the Mines Branch of the Canadian Department of Mines, gives an interesting account of two Bellevue explosions which occurred on Oct. 31 and Dec. 9, 1910, this account forming a part of his report to the Minister of Mines.

"The Bellevue mine is one of three mines operated by the West Canadian Collieries Co., Ltd., and is situated near Hillcrest Station, Alberta, on the main line of the Crows Nest Pass division of the Canadian Pacific Ry., and is in close proximity to the divisional line between the provinces of Alberta and British Columbia.

Explosion in Idle Mine

"On Oct. 31, 1910, the Bellevue mine was shut down for the observance of Thanksgiving Day, and in consequence there were no men working in the mine. Some men were engaged in erecting a power-transmission line over the surface of the ground, immediately above the underground workings, and they were much surprised to see a cloud of dust and débris issuing with considerable force from the mouth of the chutes into the open air. On an investigation being made by the mine officials it was found that the explosion doors of the ventilating fan had been blown open, and at the surface openings débris was thrown all around.

"Knowing that no men or lights (even safety lamps) were at that time in the mine, it seemed hard to explain why a mine explosion had taken place, and considerable anxiety was felt as to the probabilities of a second like disaster following the first. After the damage of the first explosion had been remedied and the ventilation restored by a renewal of the air stoppings, etc., the mine resumed work."

Mine Explodes Again

On Dec. 9, 1910, a like occurrence took place, but in this case, unfortunately, men were working in the mine. Evidently it was an explosion, or culminated in an explosion, and was not merely a roof fall because men were burned quite severely.

The second jury called in the case declared that thirteen men came to their deaths by carbon-monoxide poison, and one by the combined effect of that gas and the fracturing of his skull, the said gas and fall of roof being caused by the caving of the rock over coal chutes 76 to 78 within the mine.

However, the mine was a gaseous one, and a cave of the roof may not have been the cause, or contributing cause, as it probably was in the mysterious disaster of Thanksgiving Day of the same year. Yet Mr. Hudson remarks in his report that the explosion appeared to have started at a point where no men were working. "All the men who were in the working faces gave evidence that the explosion came from the older section of the workings, the force of the explosion being concentrated in the district from chutes 50 to 80."

Roof Falls Given as Cause

Mr. Hudson further remarks: "One important point which did not come out in the evidence is that a stratum of rock situated in the roof immediately over the coal is composed of a coarse-grained sandstone highly impregnated with iron, so that when two small pieces are struck together vivid sparks are emitted. It is affirmed that matches, pipes and tobacco were found on one of the bodies recovered from between chutes 53 and 54, but this allegation was by common consent declared to have no bearing on the explosion.

The theory that I would suggest as being the probable cause of the disaster is as follows: It is known that a large body of rock fell from the roof in the vicinity of chutes 70 to 80. The rubbing and grinding of the rocks as they fell, emitted sparks at a high temperature. The heat generated by the friction and the concussion of the rock raised the temperature of the air and gas to a high point, so that it would require only a spark of comparatively low thermal intensity to reach the ignition point of a small volume of hot explosive gas. That the defective state of ventilation in the old workings was favorable to explosive conditions was manifest; for the air passed only by leakage through the board stoppings on the main gangway, and not by a direct current. Hence the air was in a sluggish condition, and consequently when the explosion occurred, a large volume of carbon-monoxide gas would be formed without much demonstration of explosive force. Mr. Brownrigg, one of the fire-bosses, informs me that where a piece of roof falls on the wrought-iron sheets in the chutes, a continuous streak of vivid sparks can be seen, and also that when a chute is abandoned, the sheet iron is left in place."

Similar Mysterious Explosions

It is probable that the causes given by Mr. Hudson are indeed correct. The fact that none of the men were killed by the violence of the explosion almost proves conclusively that they did not cause it by an ill-placed or windy shot, or by tampering with a safety lamp. The Adrian explosion of Nov. 9, 1911, started apparently where no men were working. Another explosion occurred at the same workings many years before, also when the mine was idle. No men were found in the mine when it was searched, nor was it discovered that any men were missing. At Maindy colliery in the Rhondda Valley of Wales, a violent explosion occurred when the mine was idle, the fact not being known until the next day. A disused heading in the Pentre working of the same valley was the scene of an explosion when no one was in that section of the mine. Thus it is no new thing for explosions to take place without human agency.

Chemical Changes in Coal Formation

The following article is abstracted from remarks made by Vivian B. Lewis in a recent series of addresses before the Royal Society of Arts, England. The lectures bear a common title "The Carbonization of Coal."

The chemical theories which have been brought forward to explain the present chemical condition of coal nearly all start with the assumption that the original material from which the coal has been formed is $n(C_6H_{10}O_5)$. This empirical formula represents the class of bodies known as "Celluloses." The ratios of the atoms in these bodies lend themselves to an easy explanation of the formation of various kinds of coal. Different proportions of the known gaseous products of the checked decay which take place during the formation of peat, lignite and coal, i.e., methane (CH_4), carbon dioxide (CO_2) and also water (H_2O), are subtracted plausibly enough from the originating substance.

Oxygenation vs. Dehydration

Some theorists have held that the infiltration of water holding oxygen in solution caused reactions by which these compounds were evolved. Thus the carbon was concentrated in the carbonaceous material. Others have looked upon the reactions taking place in the original cel-

'lulose as one of dehydration. Both are probably right in some degree. The conditions under which coal has been formed are so various that cases could be found to support either theory.

Moreover such theories are rendered invalid by the fundamental errors of supposing that nature is dealing with purified cellulose, and that the various coals are definite compounds that can be represented empirically by a formula.

Our only knowledge of the coal plants is derived from their fossilised remains. Owing to the complete nature of the destruction that has taken place in structure the evidence to be obtained is small indeed. While of a totally different and far more simple form than is ours today, it must be true that the plant life of the carboniferous period which gave rise to our coal deposits varied as much in character as does the sphagnum of a peat bog from the timber of a forest.

Chemical Differences Due to Origin and Geologic History

Although the vegetable fibers of all forms produced by plants contain cellulose, they also contain ligno-cellulose and other allied compounds. Moreover they vary in the extractive matter of their sap to a very great extent. Even if we suppose that they all underwent the same treatment as regards time, temperature and pressure during their conversion into coal, we should expect wide differences in composition in the coal formed. Furthermore as the conditions vary even more than the material dealt with, it is small wonder that great differences are found between the coals from every bed in a colliery, and even between different parts of the same bed.

It is impossible to give accurate explanations of changes taking place under conditions of which we know only the general trend, and occurring in material, the composition of which is of the most variable character. We are met by the further difficulty that when we have the completed coal itself, its refractory behavior toward solvents and any ordinary reagents prevents our learning much more about its constitution than can be given by an ultimate analysis giving its percentage composition, or a proximate analysis showing the effect which heat has on it in causing it to yield fixed carbon, volatile matter, ash and moisture.

It is clear that in our present state of knowledge all that is possible is a generalization based upon the known facts. The truth or error of the theory will be shown by its degree of accordance with the results obtained by destructive distillation.

Twenty years ago I came to the conclusion that the most satisfactory view to take of the composition of coal was that it consisted of an agglomerate of the solid degradation products of vegetable decay, together with such of the original bodies as had resisted to a greater extent the actions to which it had been subjected. All my recent experience of the carbonization of wood, peat and coal confirms me in the opinion that this is in the main correct.

Resinous Bodies

All the plants of which we have fossilized record in our coal measures consisted of sedges and reeds, tree ferns, club mosses or lycopodia, and trees akin to the pine. In those prehistoric days, however, the conditions of growth—warmth, moisture and carbon dioxide—were such that these plants grew with a succulent freedom and rapidity unknown in latter days. These conditions rendered their tissue an easy prey to decay and fermentation, actions which left only the more resistant unchanged. The work of Morris, Carruthers, Fleming and Huxley has shown us that the bituminous matter in coal is largely derived from the spores of fossil mosses akin to the lycopodia.

If we take the club mosses of today we find that their spores give us that body known as lycopodium, a substance so resinous in its nature that it resists the action of water and is used to coat pills, while the same resinous characteristics render it so inflammable that a little blown through a flame provides the theatrical world with its artificial lightning. Spores of this character from the giant growths of the carboniferous period, together with the more resinous portion of plants akin to the pine, are the substances which have resisted the actions taking place during the ages which have elapsed during the formation of coal.

Mineral Compounds Inert to Carbonaceous

Of all the multitude of changes taking place in the formation of coal we only know about those involving the constituent elements—carbon, hydrogen and oxygen, but it is improbable that the mineral bodies in the sap and fiber of the original vegetation play any important part in the actions which brought about the change. For the reduction of sulphates to sulphides, and the combination of the sulphur with iron from the surrounding soil to form pyrites and organic compounds containing sulphur, and the deposition in the mass of other water-carried salts, all tend to the production of the ash of the coal, and do not interfere with the carbonaceous material in its main changes.

In the same way nitrogen compounds, which are found in every fuel of vegetable origin, are present in all stages of the formation from peat to coal. Yet it is impossible to suppose that they play any part in the change. Water, although it is probably an active factor and also a product in the decompositions, cannot be taken into account in tracing the actual course of the changes from analyses of the body produced.

Soluble and Insoluble Bodies

Starting with the fiber of the original plants we find two well defined bodies—cellulose, as represented by cotton fiber, and lignose, as represented by jute fiber. In the former the percentage of carbon is 44, in the latter 47, each giving distinctive reactions with dilute acids at 70° C., with aniline sulphate, with the Schultze solution, and with mixtures of sulphuric and nitric acids. In the cellular tissue we find starch, and besides these bodies there are present the extractive and mineral matters of the sap. The extractive bodies are those which can be dissolved out of the coal without change in composition.

Among the extractive matters we find gums, such as those which exude from the acacia and cherry. But these are also present in the juice of many plants. Mucilage, vegetable jelly, which gives many juices their power of gelatinising, resins, essential oils and other well defined bodies can all be extracted from coal by solution. In some forms of vegetation the essential oils undergo oxidation and form resins, and these being more resistant to change accumulate in masses of decaying vegetable matter, so that large quantities of them are found in lignite beds in a fossilized but little changed state.

The changes in the carbohydrates and extractive matters depend largely upon the conditions of decay. Given moisture and air, they become converted into carbon dioxide and water; check the decay by cutting off free access of air, the action is slowed down and the gases evolved are carbon dioxide and methane.

High Voltage

It will not be long before it will become necessary for our collieries to produce electricity at the mines for transmission to the various points where power is used, thereby saving the expense incurred in lengthy railroad haulage. The *Génie Civile* states that a primary tension of 100,000 volts, while exceptional, is already utilized in regular practice in several installations of the United States and of Canada,. notably that of the Ontario Power Co. Such voltage has just made its appearance in Germany at the installation of the Metallurgic Society of Lauchhammer. This company possesses some power stations in Saxony and Prussia. A central station has been erected generating 20,000 kilowatts. This station is located at Lauchhammer near the coal mines there. It includes 12 water tube boilers, 4 turbo-alternators of 5000 kw. apiece, from which the current at 5000 volts is transformed to between 100,000 and 110,000 volts for the main transmission lines.

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

To metal miners the word "conglomerate" means a heterogeneous mass composed of fragments of preëxistent rocks. In coal-mining parlance, this same word means R. A. Quin, general manager of the Susquehanna Coal Co., Mineral Railroad and Mining Co., Summit Branch Mining Co., Lytle Coal Co., Lykens Water Co., etc. In brief, Mr. Quin is one of the cornerstones of the Pennsylvania Railroad Company's extensive coal holdings in the anthracite field. Hewed out in the quarry of experience by such pioneers as Morris Williams, he has proved a reliable support to the structure built by those who fashioned and placed him.

Oh, yes! you want to know what all this has got to do with the term "conglomerate"? Well, when a fellow's name and nature are Irish, and he has a German father, and Welsh mother, in addition to having been born in Pottsville, Penn., that's crowding a sufficient number of diverse things into one coherent mass to justify Noah Webster's idea that the net result is a "conglomerate."

And speaking of Pottsville, reminds me of one thing. It's just as necessary to graduate from the Pottsville High School to become a manager of a big anthracite coal company as it is essential to be born in Ireland before you can get a job on the New York police force. Besides Quin, there are Huber, Zerbey, Baird Snyder, and a lot of other six-cylinder, high-powered humans whose names illumine the honor roll at the P. H. S. In fact, I am not sure but that Richards, chief executive driver for the Reading Company, slipped over from Minersville, only four miles away, read his second primer and partook of that feast of knowledge supplied by the Pottsville teachers.

Most men have hobbies and Mr. Quin is no exception to the rule. When he isn't working on some scheme to increase output and decrease costs, you can safely figure that he's telling a new story or listening to the recital of a rejuvenated joke. When asked a question to which he doesn't care to give a direct reply, it's two to one he'll say, "Well now, I'll tell you. You know the story of ———," and when the tale is ended, you're fairly sure to have the answer to your query.

Starting as an office boy for the Pottsville Iron and Steel Company, Mr. Quin on his 18th birthday attached himself to the Lehigh Valley engineering corps at Lost Creek, Penn. This job held him four and a half years, when he changed

to a position in Reading, on the city engineering corps, under the direction of Harvey Tyson. His stay in Reading was limited to five months, after which he returned to Lost Creek and was assistant bookkeeper in the company store for six months.

His next position was on the Penn. Geol. Survey under William Griffith and Frank Hill. This job held him in Scranton for more than a year, when he was transferred to Pottsville on the same class of work. Concluding his employment on the State Survey, Mr. Quin identified himself with A. B. Cochrane and Son, civil and mining engineers in Pottsville, and remained with this firm for nine years.

On Jan. 1, 1898, the Shipman Koal Co., Shamokin, Penn., needed a superintendent, and Mr. Quin was selected to fill the place. While serving the Shipman people, he sunk the shaft at Shamokin that is still in daily operation. At the end of fifteen months, "R. A." was made superintendent of the William Penn colliery of the Susquehanna company at Shaft, Penn., and his rise to the general managership of this same company was rapidly effected.

Mr. Quin isn't just the sort of man who can look at a four-column row of figures, wet his pencil and write the sum total. Such genius generally can be hired for the salary of a second-class clerk. Mine managers of the Quin type have talents that consist more in a capacity to labor intensely, than in any marvelous ability as mental acrobats.

Mr. Quin's success in the management of companies producing 4,000,000 tons and employing 12,000 men may be attributed principally to his personality—his marked skill in developing teamwork. Loyalty is his maxim, and duty with him is a principle, not a sentiment. He teaches that "communion is strength, solitude weakness," and believes the evolution of coöperation is in direct proportion to the evolution of civilization.

There is no doubt but that Mr. Quin's unassumed modesty has heightened other qualities in the man. His is a true virtue entirely compatible with a proper estimate of self-worth, and not demanding the denial of merit. He meets his subordinates on an equal, but dignified plane, encouraging them in the belief that we differ only in virtues, not birth. He asserts, however, that the man who thinks himself inferior to his fellows, deserves to be, and generally is.

R. A. Quinn has the enviable faculty of seeing the happy side of things, no matter what the outlook. His philosophy embodies the belief that, "in pain, we should recognize the effort to restore health, and that trials are merely matters of correction and discipline." According to his idea, every optimist is an asset to the race; every pessimist a dead loss.

Early recognizing that all effort based upon motives which are not just will ultimately fail, Mr. Quin has so shaped the policy of his company as to secure the faith and confidence of his employees. As an example of his practical philanthropy, he long ago suggested to the men that instead of all the miners at a colliery staying idle to attend the funeral of a fellow workman, they should appoint a committee to be present at the funeral, while the others work as usual and donate a portion of the day's earnings to the widow. When this is done, the company also makes a substantial contribution, takes charge of the total amount that is created, does not ask for rent if the widow lives in a company house, and apportions out the fund to her as she needs the money. This practice is heartily approved by the company's employees.

It is also noteworthy that the Susquehanna Coal Company under Mr. Quin's management has developed a system of "first-aid to the injured" that is a model plan worthy of imitation. All of his collieries have stations equipped with complete sets of rescue apparatus.

COAL AGE

The British Strike

The strike in Great Britain naturally arouses more than ordinary interest in the United States, because of the hope it holds out to us of securing a market for coal, because of the indication it gives of the possible trend of events in the American coal labor market, and because it affords such a clear indication of the terribly disastrous results which must follow a complete withdrawal of coal from any market.

We do not believe that the strike will last long, because we are convinced that Great Britain is not ready to face disaster, bankruptcy and starvation. Something will be done to remove the deadlock. It may not be a just solution. It may well be a solution as economically unsound as are other English decisions of recent date. But the British public cannot permit the idleness and grinding poverty which will descend on the millions who will be thrown out of work as a result of the strike, cannot endure long the frequent conflicts which must ensue between the police and soldiers and the starving people.

Strikes in England are often of long duration; one readily recalls the strike among the quarrymen in the Penrhyn slate quarry and those of the stevedores and lighters at many of the ports. More extensive strikes are usually shorter, and those which touch the vital interests of the British people last scarcely over night. One recalls how speedily the recent strike of railroad hands collapsed. Yet this strike did by no means paralyze England as completely as does the coal-mining suspension of today. The sea was still open for transit and much of England's business is sea-borne. It was the fear of invasion which stilled that strike and it may have a similar effect on the coal controversy.

The strength of the present revolutionary "Government" of Great Britain, we use the word in the British sense, is not considerable. In fact, the Unionist party, which opposes Home Rule for Ireland, is the strongest party in that branch of parliament which has control. The "Government" has the support of the Laborites, Parnellites and Anti-Parnellites, and these three smaller parties give the government its whole majority, enough to enable it to pass any bill which satisfies at once the Laborites and Anti-Parnellites, and they are usually at peace with themselves and the "Government."

Parliament is now sitting. It has no constitutional restrictions but its own autocratic will. The upper chamber might be expected to curb the lower. While this chamber would like to do so, it does not feel it safe after the recent conflict. So full power is invested in the present ministry and its following in the "House" to do just as it will.

The temper of Mr. Asquith and his associates forbids us to think that they would hesitate at any price to promote peace. His associates believe firmly in alleviating the conditions of the working classes by perpetual contributions from the National purse. Seeking only the more obvious remedies, they have no sure hold on basal economic truths, and have little fear of the risk of making the working classes paupers on the state bounty. Mr. Asquith's assertion that it will be the duty of the Ministry to introduce and force the passage of a "minimum wage" bill, has not developed the situation at all. His line of reasoning could have been readily forecasted.

We may look for drastic measures therefore, which will have the concurrence of the richer people. The rich will begrudgingly prefer any measure to anarchy, and anarchy seems very near at hand as a result of the economic heresies now freely circulating in England.

"Restriction of output is going to put everyone to work," "the English capitalist must be content with 3 per cent. on his money," "a man must be paid a living wage whether he earns it or not," these are a few of the suggestions which are agitating the people and controlling the government of a country which in the past produced economists like Adam Smith, Malthus, Ricardo and Marshall.

Mere sentiment and opportunist palliatives have replaced reasoning.

The operators of South Wales oppose a settlement. They argue that they have an arrangement with their men which has yet some time to run. The men, however, desire to strike. Only 15.1 per cent. believe that in the long contest last year enough and more than enough suffering was endured.

About 60 per cent. of the English operators, it is said, are willing to treat for a minimum wage. This wage is not so likely to be unfair in the British Isles as it would be in the United States, because owing to the prevalence of longwall workings, closer surveillance is possible than could be attempted with room-and-pillar methods.

It must be conceded also that the miner of Great Britain, though not putting out a tonnage in any way comparable with that of the miner in the United States, is subject to a severe restriction in his activity due to the high temperature of the mines being combined with maximum humidity. It is well known that such conditions are enfeebling to the body and enervating to the mind.

But everyone knows that on his own soil, partly by reason of the prevalent dampness, and partly as a result of ill considered trades unionism, the British workman will not do all that his strength and health will permit. It does not matter why he fails to do a fair stint of work; the fact is just as clear that he needs the energizing impulse of a piece-work price, in any event, and not less so when in an "abnormal place" where clays, binders, faults, pitches and dips prevail. It is to be hoped that the minimum wage will not be forced on the operators of Great Britain by act of Parliament. It is an economic blunder of an extremely grave kind, and will be thrust on an industry where conditions are sufficiently simple and normal that a piece-work price can best be applied, and where competition of a severe kind confronts the operator in every over-sea market.

This competition to which reference is made can never come from the United States as far as European trade is concerned. So long as these states continue to be large producers of grain and iron, it is assured that whether the ships on which our products cross the seas are ours or the property of others, there will be no space left in the holds for coal so long as more valuable freightages can be secured. We may gain a hold during a foreign strike, but the difficulty over, our coal must find its market on this continent. It will be a sorry day when our coal goes regularly across the Atlantic. In that day the United States will be so peopled that it will no longer export grain, and almost all hope of future expansion will be gone. Coal is not and, for many years, will not be the natural outgoing freight of self-sufficient and exporting nations. While coal sells at its present low price in most of the world's markets, its shipment will continue to be either for short distances or as ballast.

The Mines and the Schools

We have often wondered that mining is not being taught in our public schools. Many mining towns are solely inhabited by people whose entire support is derived directly or indirectly from the mining of coal. There is no training which will so well fit the children of such parents as one which will pertain to the mining work going on around them. No teaching will, in like degree, attract the interest of the scholar; no lessons can so effectually aid the truant officers as those which will cast a foregleam of the conditions under which the future work of the boys will be conducted.

Owing to the absence in colliery villages of any scholars but those whose male relations are engaged in mining, it will not be necessary to instruct those whose interests are in some other trade, agriculture for instance, in the practice of a trade for which they will have no use.

We are met by the time-honored objection which we have so often heard, that there are too many studies in the schools of today; the children have no time to become proficient in them all. Perhaps this is true. It is most certainly an indubitable fact that they do not become as proficient as we have a right to expect. But, for the sake of so valuable a course of instruction, why not pass up analysis, which never made a correct writer, or civics, a record of the fleeting political expediencies of men, or much of the history which is only learned to be forgotten. Compared with vocational teaching, all other teaching seems foolish. An adjective voices the conclusions of the centuries. Such a vocational training has been dubbed suggestively by our forebears as *academic;* mere mental gymnastics; it has nothing to do with the stern realities of life.

Some have said that there is nothing humanizing or broadening in a vocational training. We are not referring to those who have made a frantic appeal for Greek and Latin roots as the only pabulum for children, but to those who feel the urgent need for imparting ethical training and who believe that it is imparted most effectually by history, geography, physiology and literature. We hold with them that the training which is purely mental is not sufficient for the developing child and the coming citizen. But is not a vocational "reader" a fit place for moral lessons? It could be filled with tales of heroism, replete with stories of manly forethought. The complete modern vocational training teaches not only how work is done, but how to protect and help the worker. First aid and rescue work are more morally uplifting than a knowledge of the bones in the human anatomy or of the number of counties in the State of Pennsylvania. The child in his imaginative years will conjure up all sorts of visions of the salvage work he will feel destined to do when he takes his place side by side with the veterans of the mines.

An objector takes the view that we are training the boys to be mere miners; we ought to make them lawyers, doctors, teachers or at least make farmers out of them. Those who thus argue should be requested to supply the market with coal without the employment of miners. If the boys of our colliery towns are to be urged not to enter the mines because they are dangerous, unhealthful, stunting places, these boys must be replaced by others or mining will cease. If it were not for the cost of coal when dug by such sentimentalists, we might wish that such had the digging of it.

But mining is healthful work, makes strong and independent men. It may be doubted if any man except the farmer is more free to come when he pleases, to work when he likes, or to leave when he wills. In the bituminous regions he is almost entirely unrestrained and it is noteworthy that the farmers in some sections are quite generally adopting this so called undesirable toil and are never to be weaned from it when once the choice is made.

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

The Fireboss Question

I have read with much interest the article in COAL AGE, Nov. 18, page 190, entitled, "A Fireboss Suggestion;" and also the "Letter From A Working Fireboss," Dec. 2, page 254, and another "The Fireboss Problem," Dec. 16, page 321, from a fireboss of West Virginia. I am a fireboss in the Pittsburg district and have had a wide and varied experience while working in the employ of different operators in this part of the state. I must say that the letters of these firebosses are striking close to the mark. There is undoubtedly but one solution to the fireboss problem as it stands to-day, and that is to be found in government employment of all firebosses.

Today the fireboss is considered only a necessity thrust upon the operator by the mine law—something that he must have if he wishes to operate the mine, but for which he would otherwise have little or no use. Article 5, Section 3, of the bituminous mine law of Pennsylvania, 1911, will prove a big help to many firebosses whose duties are so prescribed as to make it impossible for him to perform the work of mine foreman or assistant mine foreman while making his second trip through the mine. The law, however, does not prohibit the mine foreman or assistant mine foreman from performing the work of the fireboss, which they have been known to do in some instances, on idle days when the mine is not working full time and only part of the men are in their places. On such occasions the fireboss, who is generally paid by the day, is laid off and his earnings much reduced, while his living expenses continue, and his work is given to the monthly men to perform.

Such are the conditions existing throughout a great part of the Pittsburg district to-day. Of course, this may not all be the fault of the operator. In many cases, I believe that the operator is not to be blamed for the existing conditions, but that the superintendent and the mine foremen at many mines do this, in order to make a record for themselves by cutting expenses, regardless of the injustice done to the fireboss. There are still however, some good mines in the Pittsburg district where the fireboss is well treated and his work given the importance it deserves, but they are few.

But since a few good companies cannot relieve the situation for firebosses working for other companies, whose officials are less considerate, I believe thoroughly that there is, as has been suggested, but one solution to the problem. In order that the fireboss may have an equal chance with the other mine officials to earn his living, and that he may not be compelled to work between two fires to which his position virtually exposes him, he should be a government official, and under the control of the mine inspector of the district in which he is employed. He would then be able to perform his duty fully and in compliance with the law, without fear of losing his position.

I would suggest further that there should also be a law passed or the Department of Mines should make a ruling prohibiting mine foremen or assistant mine foremen, who are regularly employed as such, from acting in the capacity and in place of the fireboss, except in case of emergency. I have never written to any journal before, and perhaps I have done poorly this first attempt, but I hope you will print these few lines and that other firebosses will take up the subject and give their suggestions, so that we can get one another's opinions and secure for the work of the fireboss the respect and recognition it should command.

A FIREBOSS.

Western Pennsylvania.

Shot Firing in Mines

Letter No. 1—Replying to "J. N.," in your issue of Feb. 17, p. 619, who asks for a discussion of the question of firing two or more shots at one time in one place, I would say that the only advantage gained in firing more than one shot at a time, in a single working place, is when one is about quitting for the day and does not expect to return to his place. He will then not be obliged to work in the smoke or to wait for it to clear.

On the other hand, the risks of firing two or more shots at one time, in a single close place, are many. The practice is always dangerous.

First, assuming a shot is placed on each rib and fired by either squib or fuse, one of these shots may possibly hang fire and cause the miner to think that both shots went off together, in which case the shot that has not gone off, is liable to explode when the miner returns to his place.

Second, one of the shots may release a pocket of gas, and the other set off the gas that has accumulated.

Third, if the place is dusty the first shot will probably raise more or less of a cloud of dust that will be fired by the second shot. This will produce what is called a "windy shot," or possibly a local dust explosion.

Fourth, a miner often drills what he calls a "chance" or "dependent" shot, which is intended to go off first and break down the coal, so as to give the second shot a better opportunity to work. If both of these shots are fired together, the chance or dependent shot may hang fire or fail to go off at all. The second shot will then prove to be a windy or blown-out shot and may create much havoc.

The practice of firing two or more shots at one time is also unsafe on account of roof conditions, since the miner will always have a better chance to reset the props knocked out by the shot, when a single shot is fired at a time.

DAVID FULTON.

Marion, Ill.

Letter No. 2—The firing of shots in mines depends greatly upon the conditions existing at the working face. The firing of a shot almost invariably produces a certain amount of flame, which is projected into the air at the time of firing. The safest method is to fire but one shot at a time; and to allow a sufficient interval between shots for the ventilating current to mix with and render harmless the products of combustion resulting from previous shots and to carry off any coal dust that may have been thrown into the air by the force of the previous blast. The interval of time that should elapse between two consecutive shots will differ with the local conditions and the amount of ventilation; but, in ordinary mining practice, this interval should never be less than five minutes for shots fired in the same working place.

More than one shot should never be ignited at the same time in any one working place, unless the firing is done by electricity or by fuses of such length that neither of the shots will explode in less than five minutes from the time they are lighted.

When successive shots are to be fired in any working place in which the roof is broken, or faulty, the smoke must be allowed to clear, and the roof must be examined and made secure before firing the second shot.

NOAH BURTON.

Anglin, Ky.

Letter No. 3—The question of shotfiring is of paramount importance both to miners and operators, and the discussion of this subject as suggested on page 619, COAL AGE, Feb. 17, will prove beneficial to all parties interested. This question, like the one just discussed in your paper; namely, "Sealing Off A Mine Fire," is one that requires a careful consideration of the conditions, both natural and physical, which are different in different localities. Opinions will of necessity vary and no doubt men of wide experience will disagree as to the advantages and disadvantages derived from firing two or more shots in any working place at the same time.

In considering this question it is necessary to know the kind and amount of explosive used and the means employed to fire them. Firing shots "on the solid," charged with black powder or a mixture of dynamite and black powder, as practiced in some mines, should be strictly prohibited. Such a method of shotfiring has been the cause of many disasters, although many mining men are not willing to admit it. To my mind the best method of firing shots in a mine is to fire all shots in one working place, at the same time, by means of electricity and not by the use of fuse. The number of shots allowed each working place should be fixed by the management. All shots should be tamped and fired by competent shotfirers after all the men are out of the mine.

The most important regulation in connection with shotfiring, and the most neglected one, I am sorry to say, is the restriction that no shots be fired in any place where a large volume of cool fresh air is passing; as, for example, on the main slope heading, and the new headings just turning off the slope heading; or, to use a familiar term, in places on the "first of the air." The firing of shots in these places has in many instances been the origin of serious mine explosions. In order to eliminate the danger from this cause the heating of the intake air will often prove effective; but, in addition to this, I would advise the keeping open of at least two crosscuts near the face of the places where the shots are to be fired and, also, the slowing down of the fan during shooting hours, although many will question the wisdom of such a procedure.

The advantages of the above method are, in my opinion: (1) increased safety; (2) fewer missed shots; (3) better results; (4) reasonable cost. By the old method of shooting with fuse or squib there is great liability to accidents due to "windy shots"; shots hanging fire; use of short fuses; premature explosion of charge; falls of roof, and the inhaling of poisonous gases produced by the shots.

By the use of permitted explosives tamped by competent men and fired by an electric battery when all persons except the shotfirers are out of the mine and the ventilation properly controlled so as to avoid shooting into a large supply of cool fresh air, the above dangers may be entirely eliminated. For the past two years we have been following the above outlined policy, at our mine, with marked success, and the results are most gratifying both to the miner and operator.

EDWIN HUSBAND,
Mine Foreman, Virginia Mine.
Bessemer, Ala.

Sealing Off a Mine Fire

Relative to the best method to employ in sealing off a mine fire that has gotten beyond control, will say, that my experience in both gaseous and nongaseous mines has been to either slow down the fan, or place a regulator in the entry (depending upon conditions in other parts of the mine) so that just sufficient air will be supplied to enable the men engaged in fighting the fire to work comfortably.

Then remove the nearest crosscut stopping outside of the fire, and place the first brattice on the intake side as near as possible to the trouble. The stopping on the return side can then be placed at the most available point in the return, but as near the fire as possible, in order to inclose the fire zone in a small area; place a metal pipe with a valve, in one or both of the stoppings, to test the temperature when desired.

We have found it necessary at times to lead a temporary brattice from the open crosscut along either entry to get the stoppings near the fire.

J. E. PETTIT,
State Coal Mine Inspector.
Salt Lake City, Utah.

Should Ventilation Be Reduced Before Firing Shots

The article entitled "Causes of Iowa Mine Explosions," by John Verner, p. 545, COAL AGE, Feb. 3, draws attention again to the question of reducing the air current in a mine, just previous to the time of firing, and revives the discussion as to whether or not it would be practical to stop or slow down the fan ventilating a mine, say for 30 min. before firing time. This is an interesting question, and should be thoroughly discussed.

Mr. Verner advances the argument that a draft of air in a mine increases the danger of an explosion, while a slow or feeble ventilating current reduces the liability of explosion to a minimum. Can we not have a thorough discussion of this question by practical mining men who have had experience along this line? We would be glad, also, to see this question thoroughly explained in the columns of COAL AGE.

U. S. WILSON.
Dayton, Tenn. NELSON RIGSBY.

Taffanel Barriers

Mr. Lindrooth, in his timely note on stone dust shelves in the issue of Feb. 24, fails to state correctly the origin of the device. It comes, perhaps, *via* England, but the invention, I believe, is that of Jules Taffanel, the distinguished director of the Liévin (France) Experimental Station organized by the Comité Central des Houillères. This station is most complete and the results of its experiments set the pace for the rest of the scientific mining world. About a year ago, the Cross of the Legion of Honor was conferred upon M. Taffanel with a note in the Journal Officiel that his experiments at Liévin had been "pursued by methods and with a scientific insight which were universally admired." He is *the* great authority on the coal-dust question. In a report on the experiments carried out at Altofts (England) by the Mining Association of Great Britain in 1910, M. Taffanel says, "Like ourselves, they (the British) recommend general schistification as a practical means of lessening the probability that a coal-dust explosion will occur. As for the arresting barrier (arrêt barrage) used at Liévin as an additional precaution for stopping an explosion, that is on the way to becoming general, they do not speak of this explicitly, not having tried it; but by analogy and example they suggest the use of similar arrangements for increasing the efficacy of schistification."

After a recent visit to M. Taffanel's splendid testing gallery and to many continental mines, the writer can say that experiments have already shown the efficacy of these "Taffanel barriers." They are being quite generally introduced in the mines of France and on the Continent in general to form limiting zones. I observed many already installed in the mines, and many more were planned. In most cases, fine ashes were placed on the overhead shelves. The simplicity and cheapness of the device are as much to the credit of the distinguished inventor as is its efficacy.

A. B. JESSUP, Mining Engineer.
Lehigh Valley Coal Co.,
Wilkes-Barre, Penn.

Air Ducts for Mine Fires

In reference to the article in your issue of Feb. 10 on "Collapsible Air Ducts for Mine Fires," I would say that these ducts or brattices are not, as stated in the article, an Austrian product, but are covered by a German patent, and have been made for a number of years by a German mine-supply house.

Should any of your readers be interested in obtaining further information on the subject, we can get for them further descriptive matter.

Inquiries of General Interest

All Questions Must be Accompanied by Name and Address—Not for Publication

Can A Miner Fire His Own Shot?

Please state whether a bituminous mine foreman in Pennsylvania in charge of a gaseous mine can permit, according to law, any miner to charge, tamp and fire his own shot, assuming that the man is competent of performing this work with ordinary care.

MINER.

Johnstown, Pa.

The new revised (1911) bituminous mine law, Article 4, Section 14, provides that: "In such portions of a mine where explosive gas is being generated in quantities sufficient to be detected by an approved safety lamp and in which locked safety lamps are used, the mine foreman shall employ a sufficient number of competent persons who are able to speak the English language to act as shotfirers whose duties shall be to charge, tamp and fire all holes properly placed by the miners, and to refuse to charge any holes not properly placed." This section further specifies that "No holes shall be fired by any person other than a shotfirer," and requires that "Each shotfirer shall keep a record of and report to the mine foreman, every hole that he has refused to charge, every blownout shot and every hole that has misfired."

Taking this section 14, thus far, it would seem to be the intention of the lawmakers to restrict the firing of shots, under the conditions named, to competent persons appointed by the mine foreman to act as shotfirers, the apparent meaning being to delegate this work to persons other than the miners themselves. This meaning is further strengthened by the fact that the shotfirer so appointed has the authority, by law, to refuse to fire any shot, that is (in his opinion) "not properly placed." It is significant that, if a miner were appointed to fire his own shot, he would not, in any case, refuse to fire such shot, with the result that a dangerous shot might be fired.

There seems, however, to have been added to this section what may be called a "rider", which authorizes the mine foreman to permit miners to fire their own shots; at least this is the meaning by implication. The clause reads "It shall be the duty of shotfirers and miners who are permitted by this act to fire their own shots, to visit and examine the places where shots have been fired, before leaving the mine, to see that there is no fire or any other danger existing."

Taking the section as a whole, we would say that a mine foreman in charge of a gaseous mine, in the bituminous district of Pennsylvania, is authorized by law to allow a miner to fire his own shot under the conditions specified. We would suggest, however, that the wording of the law leaves room for argument.

Methods to Be Adopted to Avoid Squeeze

In a mine where I have been employed the general method of working is as follows: The butt entries are driven to the rise on a grade of about 1:20. Rooms are driven to the right and left of each pair of butt entries and worked "on face." The rooms are driven on 39-ft. centers, being about 21 to 24 ft. wide, and leaving 15- to 18-ft. ribs between them. The general plan of proceeding is to work No. 1 butt, advancing, and No. 2 butt, retreating. The coal is from 6 to 7 ft. thick and is overlaid with a hard sandstone roof; the floor is a hard fireclay, overlying a limestone. The coal is a hard bituminous coal.

This method gives a good deal of trouble from squeeze. Will you kindly suggest how the method can be modified so as to reduce the liability of squeeze, and obtain the largest percentage possible of coal?

Smithton, Penn. MINE FOREMAN.

Our correspondent has omitted one important factor; namely, the depth of cover or amount of roof pressure. The general plan of mining described is that in common use in the Pittsburg district. The plan has numerous and decided advantages, and when properly conducted and carried out has been very successful. It enables the operator to maintain his tonnage in the mine, and meet the necessary expenses of driving the butt entries. If it were not for this latter reason, the retreating system could be employed in all the butt entries.

There may be several reasons for the squeeze mentioned by our correspondent, and without a more exact knowledge of the facts in this case, we can only suggest what these may be.

(1) In all coal extraction it is important to leave a certain percentage of pillar coal in the first working. How much this percentage should be will depend on numerous conditions, such as depth of cover, character of the roof, floor and coal, and the inclination and thickness of the seam. A general rule in mining is to take out from one-third to one-half of the coal in the first working, leaving the remainder as pillar coal to support the roof and protect the entries till the time comes to draw back the pillars. This rule, however, is greatly modified by local conditions.

In general it may be assumed that when a squeeze has occurred the reason is that too little pillar coal has been left or too large an area has been kept open; that is to say, too large an area of roof has been left standing on timber. One of the surest remedies to avoid squeeze is to draw all standing timber, and induce a fall of roof, so as to settle the weight on the gob. Uniformity of work, in drawing pillars, is also essential. If these precautions do not suffice, a further remedy must be found, in increasing the width of pillars relative to the size of opening. This will decrease the roof pressure per square foot.

Considerations Before Drawing Pillars

What matters should be carefully considered before the work of drawing pillars is begun?

Before starting to draw pillars in a mine, it is important to consider what weight of cover is resting on the pillars. Regard must be had to the thickness of the seam; its depth below the surface; face; the nature of the strata; the hardness of the coal. A careful inspection should be made to ascertain to what extent the roof has fallen in the rooms, and in any abandoned adjoining section of the mine. If there is a large standing area in which the roof is supported on timber in the rooms, the work of drawing the pillars will be most difficult and dangerous; because the weight thus thrown on the pillars will crush the coal. It is also necessary to closely inspect the roof for any evidence of a fault or slip, as these will cause much trouble after the pillar work has been started. It is necessary to consider further the later effect the drawing of pillars will have to cause damage on the surface; and whether the disturbance of the overlying strata will allow water to flow into the mine; or whether the drawing of the pillars is going to shut off any coal yet to be mined.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Questions Asked at Fireboss Examination, Held at Cumberland, Wyo., Jan. 29-31, 1912

Ques.—What are the principal gases met with in coal mines?

Ans.—The gases commonly classed as the principal mine gases are methane or marsh gas (CH_4), carbon monoxide (CO), carbon dioxide (CO_2), hydrogen sulphide (H_2S), and olefiant gas (C_2H_4).

Ques.—Which of these gases are heavier and which are lighter than air? Under what conditions and where would you expect to find each of these gases?

Ans.—Of the gases named, carbon dioxide (CO_2), sp. gr. 1.529, and hydrogen sulphide (H_2S), sp.gr. 1.1912, are heavier than air. The gases lighter than air are marsh gas or methane (CH_4), sp. gr. 0.559, carbon monoxide (CO), sp. gr. 0.967, and olefiant gas (C_2H_4), sp. gr. 0.978.

The gases heavier than air would, by virtue of their specific gravity, tend to accumulate in the lower portions or the dip workings of a mine, while those lighter than air, for the same reason, would tend to accumulate at the roof, or in the higher portions or rise workings of a mine. There are, however, many conditions in the mine that prevent the accumulation of the gases in these several places. As a rule it is safe to assume, in practice, that each of these gases will be found, in greater or less quantity, at points near where they are generated.

However, large volumes of carbon dioxide or blackdamp (CO_2) will always be found in the lower places or dip workings in a mine generating much blackdamp. Likewise large volumes of marsh gas, mixed with air (firedamp) will generally be found in roof cavities or at the face of pitch workings, in mines generating much marsh gas. Olefiant gas is usually found associated with marsh gas. Carbon monoxide is seldom found in dangerous quantities, except in the afterdamp of an explosion, or in proximity to a gob fire, or after the firing of one or more shots in a close heading or working place. This gas is often found accumulated behind what is called a "standing shot"; or, in other words, where the coal has been dislodged and moved forward in a body but not broken down. Hydrogen sulphide is also seldom found in large quantities in mines, but may be sought in damp, low places, especially where iron pyrites occurs in the coal or the adjacent strata.

Ques.—Which do you consider the most dangerous gas found in coal mines and why?

Ans.—Carbon monoxide (CO) is generally considered to be the most dangerous of the common mine gases. This is because its presence in the mine workings is often unsuspected till too late, due to the fact that the lamps of the miners continue to burn brightly in the presence of this gas. The gas is extremely poisonous; one-half of one per cent. breathed for a short time will generally prove fatal, while a larger percentage of the gas may cause instant death. Men have been found killed by this gas, in positions that indicate they had no previous warning whatever.

Ques.—Describe the action of the different gases on the flame of a safety lamp.

Ans.—The action of the different mine gases depends in any case on the quantity of gas present in the air. Three of these gases; namely, marsh gas, carbon monoxide and olefiant gas, are combustible, and when mixed with air in proper proportions, explosive. These gases exert a peculiar influence on the flame of a safety lamp by increasing the combustion of the lamp flame. Marsh gas (CH_4) gives a well defined flame cap that is visible to the naked eye when at least 2.5 or 3 per cent. of gas is present in the air. This cap forms and is observed as a pale-blue tip above the flame of the safety lamp. Marsh gas is a light hydrocarbon gas.

Olefiant gas (C_2H_4) is a heavy hydrocarbon gas. Its combustion is more violent than that of marsh gas and, for this reason, its influence on the flame is often such as to cause the flame to jump. This gas, therefore, interferes considerably with the formation of a cap. When much is present it is difficult to observe the gas cap formed, owing to the lamp flame being less steady. The presence of much of this gas in firedamp makes the mixture more dangerous, because less easily detected. Should explosions occur in the lamp, these are more violent when olefiant gas is present than is the case with pure marsh gas.

Carbon monoxide when present has the effect of lengthening the flame of the safety lamp and increasing somewhat its brightness. The cap formed by this gas is not clearly visible and the gas must be detected more by the brightness and lengthening of the flame. However, it is unsafe to rely wholly on these indications for its detection. Other means should be used as the blood test or the canary or mouse test.

Carbon dioxide, when present in sufficient quantities, dims the flame of the lamp; when present in larger quantities the flame is entirely extinguished. This effect is due to the dilution of the feed air of the lamp by an incombustible gas and the consequent reduction of the temperature below the temperature required for the combustion of the carbon in the flame. Both marsh gas and hydrogen sulphide when unmixed with air extinguish the flame of a lamp.

Ques.—What proportion of firedamp in an air current forms an explosive mixture of the least dangerous character?

Ans.—The proportion or percentage of marsh gas in a firedamp mixture that may be considered less dangerous is where the volume of air is more than thirteen times the volume of gas, or the percentage of gas is less than 7.14. This mixture is below the lower explosive limit of firedamp, and may be considered less dangerous because the addition of more air renders the mixture less and less explosive. Any firedamp mixture above the higher explosive limit is rendered more and more explosive by the addition of air, which is sure to occur when the gas is disturbed.

Ques.—Are there any possible conditions known to you and which may occur in a mine in Wyoming that would make the combination given by you in answer to the preceding question, as the least dangerous, one of a very highly dangerous character, no further addition of firedamp being made to the current?

Ans.—Yes, the presence of fine coal dust floating in the air will render an otherwise nonexplosive mixture, explosive. Also the presence of olefiant gas in firedamp renders the mixture more explosive than it would be otherwise.

Ques.—Does the quantity of gas given off by mines vary with the change of the atmosphere, and why?

Ans.—In all gaseous mines there is evidence that any considerable fall of atmospheric pressure is always accompanied by an expansion of the gas and air contained in the abandoned places of the mine, and this would naturally increase the quantity of gas in the air current. It is probable that the observed increase in the percentage of gas in the mine air is due entirely to this cause.

Sociological Department

For the Betterment of Living Conditions in Mining Communities

Preventive Methods, Lackawanna Company

By C. E. Tobey*

Coal mining is a hazardous occupation at its best, but when you consider that from 65 to 80% of the fatalities are due entirely to carelessness or ignorance on the part of the men themselves, you will readily understand with what the companies have to contend. How to educate our men so as to eliminate this carelessness is a problem which I assure you has had more thought and discussion at our superintendents' and foremen's meetings than has been given our cost sheet. Every suggestion and idea which appeared likely to uplift our men or prevent them from injuring themselves or their fellow workmen has been tried out, and I am pleased to say that some of these ideas are producing good results.

The Extension Schools

Out of our force of 18,500 employees, 6000 of them are Polish, 1000 Slavs, 1000 Russians, 2000 Lithuanians, 500 Italians, 500 Austrians and about 500 Hungarians. A large number of these cannot even understand the English language, and it is necessary to educate them somewhat before they can understand or comprehend the company rules. It is hard to get them interested, as many of them are suspicious of your efforts in their behalf. They cannot understand why the "big boss" should take any interest in their safety or welfare, and it requires a continual study to learn how to reach them. This is being done most successfully through our extension schools, under the direction of our Mining Institutes, which were organized and fostered by our Young Men's Christian Association.

The Scranton District Mining Institute has between 1700 and 1800 members, practically all of whom are actual mine workers. At the regular monthly meetings of this institute, papers are read and discussed on various mining subjects, and demonstrations given in first aid, etc. All these subjects are very interesting and instructive to our advanced classes, but cannot be understood or comprehended by the non-English-speaking miners, and it is for their benefit that the extension schools were inaugurated. These are called extension schools because they are held at various places around the mines; any convenient hall or building in which benches and desks can be placed, or perhaps some handy district school building is used. Some bright, young, energetic mine foreman who is a member of the Mining Institute has charge of the class, and devotes two evenings each week trying to teach plain English to these non-English-speaking foreigners. Blackboards and charts are used, and the Dr. Roberts system followed. It is marvelous how some of these young foreigners grasp the meaning of English words, and when they get far enough advanced so that they can understand English, they then come to the institute, or, perhaps, join the mining class which is held in the Y. M. C. A. twice a week and presided over by a competent mining engineer.

The Magic Lantern

For the special benefit of our non-English-speaking employees, Colonel Phillips, our general manager, conceived the idea, some time ago, of illustrating the dangers of careless mining. He selected the accidents that most frequently occur, such as fall of roof, misfired blasts, etc., and had them actually illustrated before a camera in the face of the workings. Several hundred of these photos were taken, covering some thirty of the most common kinds of accidents. It took a photographer many months, and much of the time of the foremen and others, to get suitable photographs which would bring out the points desired. Some two hundred of these photographs were made into lantern slides and shown with a magic lantern before our foreign schools.

Foreman Gages Miner's Bit and Finds It Too Small

The Miner is Sent to Shop to Have Bit Resharpened

*Superintendent coal department, D., L. & W. R.R.

Note—Address delivered at Penn. State Y. M. C. A. convention, Bradford, Penn., on Feb. 23, 1912. First of two articles.

By this method instruction was provided whether the members of the class understood English or not, and no talking was necessary, as the pictures spoke for themselves. The teacher only needed to point to the illustration thrown on the sheet and either shake or nod his head, and the dullest foreigner could readily see the right or wrong way, and the result of choosing it.

Lantern Slides in Book Form

These magic-lantern exhibitions were a success from the start, and drew crowds of foreign men, women and children. They enjoyed them as much as they would the shows at a nickelodeon, and, at the same time, absorbed something for their future welfare and safety. They frequently asked to have the exhibitions repeated, and, in many instances, after the show was over it was necessary to put out the lights in the hall to induce them to disperse and go home.

Our company was so pleased with these photographs and this system of educating its foreign employees, that they arranged to have them published in book form with simple and appropriate lessons prepared on the Dr. Roberts system by J. H. Dague and S. J. Phillips, of the educational staff of the Scranton Y. M. C. A. These primers will be used exclusively in our foreign extension schools and distributed among these classes.

Careless Timberer Goes Home

Many rules have been adopted for preventing accidents and protecting the lives of our employees. For instance, whenever the roof of a chamber has been reported by the fireboss as being in bad condition and unsafe, instead of cautioning the miner when he enters the mine and instructing him to place the necessary props, that miner is not allowed to go in, but is sent home for the day while the place is being made safe by company men, the result being that this miner becomes more careful and does not allow his place to get in bad condition, as such carelessness has its effect in his pay envelope. By the old method the miner took his own time in placing the props, and frequently either he or his laborer, or both, got caught under a fall of roof as a result of his carelessness and delay. Our records show that at least 45 per cent. of the fatal accidents were caused by falls of roof in the face of the workings, and by this new rule we hope to greatly reduce this average, and, in fact, in the one district where it has been tried, we found, last February, that just before this rule was adopted, out of 952 working places an average of three per day were reported to have "bad roof," whereas in December the average was less than one room per day, and in that same district, while there were eleven men killed in the year 1910 by falls of roof, we had but three fatalities from that cause in 1911.

Misfire Means a Return Home

Necessity and self-preservation forced us to adopt another rule which was thought at first to work a hardship on the miner and a reduction in the output, but which really worked out to the advantage of all. A great many accidents, a majority of which proved fatal, were caused by misfires. In other words a miner would light his squib and retreat to a place of safety, and if the shot did not go off promptly, he concluded the light had gone out and returned to the face just in time to receive the delayed shot. Rules were laid down forbidding the man to return to the face for a certain number of minutes, but it was soon found that no definite time could be set for a delayed shot, and again, time passes slowly when a man is waiting. Although he might feel that he had waited 15 min., the fact is he may have been waiting only 4 or 5 min., so it was decided necessary to adopt the rule that no miner be allowed to return to a missed hole. He must take his dinner pail and go home for the balance of the day. There is no question but what this rule is evaded more or less by some reckless dare-devils, but they not only run the risk of being blown to Kingdom Come, but also of immediate discharge from the service if found out.

Gaging the Bit

A great many accidents happen from "premature blasts," the charge going off while placing the cartridge in the hole or in tamping it. The friction produces a spark which ignites the powder. It was a study to find out what caused this—it was plainly carelessness, but in what manner? In watching these conditions closely, one of our superintendents noticed that the paper cartridge sometimes appeared too large for the hole, and in forcing it in, it frequently happened that the cartridge became torn and the powder leaked out. Upon closer examination our superintendent discovered that the drill used by the miner had become worn down until it was not capable of boring a hole large enough for the cartridge to enter. Today, these drills and bits are regularly gaged, and, if found too small, are immediately sent out to be drawn out and sharpened, and the miner cannot resume work until he has a drill of the proper size, and we have found that the misfired shots have reduced about 75 per cent. since adopting this rule. We also have a special committee, whose duty it is to visit all our breakers, boiler houses, etc., and hunt out danger spots and recommend methods of eliminating them, and we have an Inspector of Safety Appliances, who follows up and sees that the suggestions of this committee are fully carried out.

The Drill Hole is Conformed to Standard and the Charge Can Then Be Inserted by Scraper

Is It Any Use?

In reply to your anticipated question as to whether all these precautions taken have actually saved any lives, or reduced the fatalities in our mines, I am proud to say that although in 1911 our production increased 370,000 tons over 1910, the number of persons killed in and about our mines was 15 less—and that there were 170,000 tons of coal produced for every man killed, as against 124,000 tons in the previous year. This means that 15 human lives have been saved through some source and the preservation of 15 breadwinners for at least 10 widows and 50 children, and if only one of these 15 could be credited to our efforts, we would feel amply repaid.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

The Interstate Commerce Commission recently heard arguments in the case of John W. Boileau and other Pittsburg district coal operators against the Pittsburg & Lake Erie and other railroads. The case has required many months for collecting testimony and the arguments were presented by attorneys of national prominence. Wade H. Ellis, Louis D. Brandeis and Cyrus E. Woods, among others, appeared for the operators. The complainants summarized facts in the case as follows: "The rate from the Pittsburg district to Ashtabula was not an outgrowth of competition among the railroads, but was fixed and is maintained by agreement of the carriers from the Pittsburg and competing coal fields. The rates from all districts, fixed by agreement, practically ignore differences between Pittsburg and the other districts in the matter of distance from the markets, and give Pittsburg a rate per ton per mile over 100 per cent. higher than those from the competing fields.

"The defendant railroads are, to a large extent, interested in coal properties in the fields in whose favor the discrimination is practiced. The present freight rate to Ashtabula leaves the Pittsburg operators with practically no margin of profit on their lake coal business.

Comparison with Other Rates

"Compared with coal rates from all other districts competing in the same markets, the 88c. rate from Pittsburg is the highest per ton mile, and greatly exceeds the rates from Illinois and Indiana. It exceeds the average of coal rates throughout the United States, though there is included in this average the high rates for coal moving in small volume and for short distances, and for coal moving in the mountainous regions of the West. Compared with the rates made by defendants on other commodities hauled over their lines, it exceeds the average charge on all freight (including high-class merchandise) where the average haul is about the same as the haul from Pittsburg to Ashtabula.

"The 88c. rate yields a train-mile revenue greatly in excess of the average on defendants' lines, and three to five times the average train-mile revenue on all railroads in the United States. The rate from the Pittsburg district has constantly been going up while the cost of carrying the coal has constantly been going down. The actual cost to the carriers of hauling the coal for which the 88c. rate is received is less than 24c. per ton."

The argument for the coal operators was concluded as follows:

"The carriers have put in no defense in this case because there was none available. That the cost of the service, the calculation of which they have not even attempted to refute, shows the rate charged is excessive, and out of all proportion to the expense of the service rendered, is unchallenged; that the effect of the rate on the business of the shippers has been ruinous, remains undisputed by any testimony; that a comparison of the rate in question with any rate with which it may be fairly and justly compared shows it to be out of line with all coal rates, is not disputed by any evidence; and the discrimination in favor of competing fields in which the carriers themselves have a financial interest, is not denied."

Argument for the Railroad

The defendants were represented by O. E. Butterfield, George S. Patterson, Clyde Brown, and other railroad attorneys. Their argument began with reference to a decision of the Commission in 1889, and the point was made that there is no evidence that the service is less valuable today than it was when the commission approved a charge of 90c. (1889), nor is there any evidence that it costs less today than it did then. Furthermore it was said that "the rate in question considered alone is apparently reasonable."

The point was also made that "the fact that the business in question may be profitable to the lines most favorably located, most highly improved, and most efficiently equipped, should not condemn the rate," nor "should the profits on other business be cited as an excuse for reducing the profits on coal traffic."

One of the most important points for the defendants was made by W. M. Duncan, when he said: "It seems apparent that the West Virginia and Kentucky mines cannot or will not be shut out of the lake coal business. A reduction in the present Pittsburg rate would undoubtedly, as we view the situation, be followed by a similar or equivalent reduction in the other lake cargo coal rates from the competing fields and then the Pittsburg operator would be in the same position as he is now. The railroads would suffer to the extent of the reduction."

Alabama

Birmingham—A $15,000,000 coal company for the development of the Warrior coal fields, with English capital, is in prospect, and has progressed so far that the financial backers are in this country for an investigation preliminary to the formation of the company. This information comes from L. A. May, recently returned from London, member of the New York & London Financing Co. and well known in Birmingham.

Colorado

Denver—The Rocky Mountain Fuel Co., in support of a petition for an injunction restraining the miners of the northern Colorado coal camps from interfering with their employees and committing alleged acts of violence, has filed in the federal court a large number of affidavits in which specific cases of violence, intimidation, threats of murder and arson are given in detail. One of these affidavits is by E. E. Shumway, president of the company, and he injects a new issue into the situation by charging that not only are the peace officers of Boulder County derelict in their duty, but that the employees of the Denver & Interurban and the Colorado & Southern R.R. are in full sympathy with the strikers and insult and abuse the employees of the coal company.

Illinois

Marissa—The coal miners of Marissa are promised steady work until Apr. 1 through the purchase of the maximum capacity of the mines up to that date, by the Illinois Central R.R. Heretofore the work has been slack, owing to failure of the railroads to furnish enough cars, and, as a result, the miners were leaving Marissa.

Chicago—It was announced, Mar. 1, by John P. White, president of the United Mine Workers, that representatives of miners and operators in the bituminous coal industry would meet in Chicago Tuesday, Mar. 5, to make arrangements for a second joint wage conference before the expiration of present contracts on Mar. 31.

Petition for an injunction against the Illinois Central R.R., filed by coal operators to prevent the enforcement of the railroad's new car-distribution plan was dismissed, Feb. 28, by U. S. Judge K. M. Landis. The bill prayed to enjoin the Il-

linois Central from putting into effect an order of the Illinois railroad and warehouse commission, directing that car distribution be regulated by the mine capacity of operators. An appeal from the commission's order is now pending before the Circuit Court of Sangamon County, and Judge Landis ruled that therefore the United States Court has no jurisdiction, the filing of the appeal serving as an injunction to delay the enforcement of the new schedule.

Belleville—The Belleville Savings Bank has brought suit to foreclose a mortgage of $1,100,000 on the mines of the Southern Coal & Mining Co. The mining company claims that they will oppose this suit and that it is a misunderstanding. The mines on which the mortgage is held are the following: Walnut Hill, Avery, Harmony, Oak Hill, Shiloh, Glendale No. 2, Germantown, Muren No. 1 and Muren No. 2, all located on the Southern Ry.

Danville—Officers of the Brazil Block Coal Co., who are operating the mines formerly known as the Dering Nos. 2, 3 and 4, have made out a statement showing the total payroll for the second two weeks of January; the number of men employed; the average pay per man, and the average pay of the men at the different mines. It is as follows:

Gross pay roll	$48,132.10
Total number of men	1118
Average per man	$43.05
Average per man per day—	
No. 2 Mine	$3.24
No. 3 Mine	$3.41
No. 4 Mine	$3.43

Indiana

Sullivan—Judge Bedwell, of the circuit court, has overruled a motion to quash the affidavits against the Monon Coal Co., charging that the company failed to maintain washhouses. He also held the law constitutional. The coal company will appeal to the supreme court.

Boonville—The Wilson-White Coal Co. has changed its name to the Cypress Creek Coal Co., and has elected C. P. White president.

Terre Haute—The moderation in the weather has not lessened the demand for coal at Indiana mines, and all except those on the Chicago & Eastern Illinois are operating at full capacity. Most of the present output is for storage. The dealers have in their yards enough for their trade until Apr. 1 when a suspension of work will take place through failure of the operators and miners to agree on a wage scale.

Kansas

Pittsburg—An accumulation of gas exploded in mine No. 6 of the Mayer Coal Co. in the morning of Feb. 16. Props were torn out, empty powder cans and dinner buckets sent in every direction and doors blown from their fastenings but none of the 150 men at work at the time was injured. The immediate cause of the explosion is unknown. State Mine Inspector Besson ordered the mine shut down until steps had been taken to free the mine of gas.

Turck—Mine No. 4 of the Fleming Coal Co. has been shut down by order of Mine Inspector Besson, since Feb. 2, because it was found that the company was not complying with the state mining laws. Rapid advance was being made toward old workings that are filled with water and necessary precautions were not being taken.

Kentucky

Providence—One of the largest coal-land transactions in this section for some time is now under way. Options on 5000 acres of mining rights will be taken up and about $500,000 paid to the owners. The land lies in Webster and Hopkins Counties, and was bought in by a French syndicate about two years ago.

Harlan—M. M. Hamilton and G. W. Middleton, of Shawanee, and F. F. Cawood, of Harlan County, have purchased a tract of coal and timber land lying along the Clover fork of the Cumberland river, 21 miles east of Harlan, on the extension of the Wasiota & Black Mountain R.R. The tract contains more than 300 acres and lies adjacent to the railroad right-of-way which has been surveyed up the Clover fork. It is understood that development of the property will begin at once.

Louisville—The Stony Fork Coal Co. and other coal companies of the Middlesboro field have attorneys at Washington pressing a case before the Commerce Court which promises to be of great interest to coal shippers all over the country. The defendant companies are the Louisville & Nashville and the Southern Railway Co. The point at issue is, whether an action involving tariffs, etc., may be filed in the Commerce Court in the first instance, instead of applying to the Interstate Commerce Commission and then taking the matter up on appeal, if necessary. The allegation is made that, due to disputes as to tariffs, the two defendant railroad companies refused to furnish cars to the complainants at the busiest season of the year, hundreds of empty cars standing on the side tracks in the meanwhile. As a result the coal operators lost heavily. It is suggested that a similar case was filed with the Interstate Commerce Commission from Illinois. It was not decided until one year later. Such a condition would be intolerable, it is pointed out, with perishable freight waiting to be handled or large orders of any commodity waiting on cars for moving. The decision therefore will be awaited with much interest.

Missouri

Kansas City—After a short session the conference between representatives of the locals of the United Mine Workers of America in Missouri, Kansas, Oklahoma and Arkansas and of the Interstate Southwestern Coal Operators Association adjourned, Mar. 1, subject to call. The contract of the miners expires Mar. 31, and the wage scale that will be in force during the next two years will be adopted at the meeting which, it is believed, will be held here this month.

Ohio

Columbus—The defense in the government's suit under the Sherman anti-trust act against six railroads and three coal corporations charging conspiracy in restraint of trade and monopoly of the bituminous coal industry of three states, rested its case before the U. S. Court of Appeals, Feb. 29. According to facts brought out in court, the Chesapeake & Ohio controls the Hocking Valley and the Kanawha & Michigan roads, while the Lake Shore & Michigan Southern controls the Zanesville & Western and the Toledo & Ohio Central railroads. It was stated that the Hocking Valley was bought by the Chesapeake & Ohio R.R. in order to extend its trunk line system and that the public has been much benefited by this purchase.

Attorney-General Hogan, of Ohio, has made a ruling of considerable importance in the matter of the new state mining code. The code provides that in the case of shaft mines there must be two separate and distinct shafts. The Golden Rod mine of the Guernsey Coal & Mining Co., of Newark, Ohio, did not follow out this ruling. In sinking, a hard rock formation was reached; the lower part of the main shaft was enlarged and a cement partition was used to form the two shafts. It was held that this arrangement does not comply with the law.

Oklahoma

McAlester—A deal has been consummated here whereby W. E. Beaty and associates comprising the Pocahontas Mining Co. have acquired the lease and mining property of the Indian Coal & Mining Co. at Pocahontas. The Indian Coal & Mining Co. was owned by J. A. Nichols and H. A. Miller, of Asheville, N. C.

Pennsylvania

Bituminous

Clearfield—The Conman Shaft Coal Mining Co. was recently awarded $145,830 damages by a jury in its suit against the Pennsylvania R.R. Co. for discrimination in coal car distribution. This makes the third verdict given at Clearfield

against the Pennsylvania R.R. and is the largest of the three.

Ebensburg—The extensive coal holdings of John C. Martin, near Portage, Penn., were recently sold to an Eastern syndicate. The properties comprise about 5000 acres and are being worked by 10 mines with an annual output of 800,000 tons. The new owners will not operate the mines but merely constitute a holding company and will continue the leases held at present by the various operating companies.

Osceola Mills—W. J. Davis, who for 17 years past has operated the Loch Lomond mine near Hawk Run, has recently secured control of the Eureka, No. 21 mine, at Osceola, formerly operated by the Berwind-White Co. This mine taps the "D" or Moshannon bed, which here averages 4 ft. in thickness. Mr. Davis is equipped to begin operations at once.

Johnstown—Continuing the campaign against alleged violations of the mining laws, Inspector Thomas D. Williams has caused the arrest of six men employed in the Puritain mines in Cambria County.

Du Bois—Bids have been received by the Buffalo, Rochester & Pittsburg R.R. for a 4-mile extension of the road, into Jacksonville, and it is stated that construction work will be started as soon as the contracts are let. This extension will tap one of the largest tracts of coal land in Indiana County.

Brownsville — Twenty-five Russian Poles employed at the mine of the Monongahela River Consolidated Coal & Coke Co., two miles north of here, caused a riot at that place Feb. 26, in which nearly a dozen miners were slightly hurt. Recently the miners were ordered to equip themselves with safety lamps. Nearly all the 250 men purchased lamps but the 25 Polish miners refused, and when they appeared on the morning in question, the foreman refused to permit them to enter the mine. The Poles attacked some of the other miners.

Connellsville—A new coking corporation, the Aetna Connellsville Coke Co., recently took over a half interest in the Dunlap Connellsville Coke Co. A complete new organization was effected by changing the name of the concern from the Dunlap Connellsville to the Aetna-Connellsville company and taking in new stockholders. The new company will take over the works of the Dunlap concern. They have 119 ovens in Redstone township on the Dunlap creek. At present the company is operating 79 ovens, about three-fourths of its capacity. Inability to secure labor has been the cause of not running full.

The Crystal and Madison plants of the Sackett Coke Company of Smithfield have been purchased by the United Connellsville Coke Co. of Pittsburg.

Anthracite

Scranton—The case of John W. Peale, of New York, against the Marian Coal Co. has been appealed to the U. S. Court of Appeals by attorneys for the coal company. The case grows out of a contract entered into between the coal company and Peale, whereby the New York man was to handle the entire output of the company's washery.

A piece of ice falling to the foot of the Central shaft, West Scranton, Feb. 26, smashed through the hood of the cage, killed one man and injured two. The men were removing a fellow workman who was ill; he lay on a stretcher in the cage at the time of the accident and miraculously escaped injury.

Wilkes-Barre—At a conference of anthracite coal operators in New York, Mar. 5, the demands of the miners were formally refused. A committee of ten was appointed to convey this reply to the miners' representatives at the joint conference to be held Mar. 12.

Tamaqua—A route which may prove to be an extension to the Delaware & Hudson R.R. lines below Wilkes-Barre, is being staked out by engineers who have been at work for several weeks between Tamaqua and Danielsville. The engineers refuse to discuss the matter, but it is surmised that they are at work for the Delaware & Hudson, mapping out a road that will give that company an independent outlet to the big coal fields it recently acquired in the Schuylkill region.

Washington

Seattle—At a recent meeting of the stockholders of the Crown Coal & Coke Co., at Walla Walla, R. G. Belden resigned as president and was authorized to go to Europe to negotiate a $1,000,000 bond issue for the company. The Crown Coal & Coke Co. operates on about 5800 acres in the Crows Nest Pass district, of British Columbia.

North Yakima—A 14-ft. seam of high-grade bituminous coal has been discovered on a property along Taenum Creek, near Cle Elum, Wash. A company has been organized with $500,000 capital to work the strike.

West Virginia

Williamson—It is said that the Norfolk & Western in a short time will begin the construction of a 20-mile branch from Williamson to extend into the new coal field being opened just south of here. There are 15 large operators producing coal in this field and it promises to become one of the most productive in West Virginia. The town of Williamson is enjoying an unprecedented boom and real estate has jumped to enormous values.

Fairmont—The British government has placed an order with the Consolidation Coal Co. for 12,000 tons of George's Creek Coal. This will be loaded at Curtis Bay, Md., for shipment to Gibraltar.

Wyoming

Kemmerer—At a meeting held here recently by representatives of the various miners' locals of this district it was decided to proceed at once with the erection of a hospital in Kemmerer. Representatives were present from the locals at Sublet, Diamondville, Frontier, Susie, Glencoe, Oakley, and Elkol. It was their decision to erect a strictly miners' hospital to be presided over by the various affiliated locals. The need of a hospital in this district has long been known, but previous efforts in this direction have failed. It is expected that a temporary hospital will be in operation by Apr. 1, this year.

Canada

Winnipeg, Man.—Assurance that the Canadian Northern Ry. would immediately investigate the proposition of building a line into the Taber coal field, was given recently by Sir Donald Mann, vice-president of the railway. He said that a party of engineers would be sent out this spring to locate a line into Taber.

Great Britain

London—The national coal strike, after being in force for a week, still seems quite remote from an early settlement. The miners, although practically assured of a minimum wage, continue to demand the rates called for by their own schedule. Over 250,000 workmen in other industries have been thrown out of employment. Railroad service has been cut down to a minimum and shipping is greatly hampered.

Chronology of Coal Mining for February

Feb. 1—The joint scale conference of bituminous operators and miners at Indianapolis adjourned without having reached a basis of agreement.

Feb. 2—Fire destroyed the breaker and colliery buildings of the Connell Anthracite Coal Co., Bernice, Penn. Loss, $150,000.

Feb. 6—Fire destroyed the boiler and engine houses of the North Breeze Coal & Mining Co., Breeze, Ill. Loss, $50,000.

Feb. 12—A serious mine fire broke out in the coal mines at Antonienhütte, Prussia. Twenty-seven men were reported to have perished.

Feb. 18—The plant of the Knickerbocker Briquet Co., at Murphysboro, Ill., was destroyed by fire. Loss, $100,000.

Feb. 22—A fire in the No. 5 mines of the Western Coal & Mining Co., Lehigh, Okla., resulted in the death of eight men.

Feb. 29—Over 1,000,000 coal miners in Great Britain went out on strike for a minimum wage.

Personals

Harry J. Young, for some time past salesman for the W. J. Hamilton Coal Co., has resigned to accept a position with the Consolidation Coal Co., with headquarters in Detroit.

Dr. J. A. Holmes, director of the U. S. Bureau of Mines, recently delivered an address before the Southern Appalachian Coal Operators' Association, on "Some Lessons from Recent Mine Disasters."

A. B. Crichton, mining engineer, of Johnstown, Penn., will remain in charge of the coal properties, near Portage, Penn., formerly held by John C. Martin, and recently taken over by an Eastern syndicate.

Cyrus Echard has been elected president of the recently organized Aetna-Connellsville Coke Co., of Connellsville, Penn. Other officers are: D. M. Parkhill, vice-president; Francis M. Ritchey, Jr., secretary and Joseph B. Echard, general manager.

Francis S. Peabody, president of the Peabody Coal Co., of Chicago, Ill., delivered an address before the students and faculty of the College of Engineering of the University of Illinois, Feb. 27, on "The Operation of Coal Mines from a Commercial Standpoint."

L. B. Lincoln, of Chicago, vice-president of the American Peat Society and the Peat Association of Canada, recently visited Mankato, Minn., and vicinity, with a view toward the possible development of a peat industry in that locality. Mr. Lincoln secured options on peat lands at Janesville, Waseca and Owatonna.

N. D. Monsurratt, vice-president and manager of mines of the Sunday Creek Coal Co., C. E. Fukes, chief engineer, and F. E. Knox, assistant to the president, all of Columbus, Ohio, were recently in Charleston, W. Va., and visited the Sunday Creek company's plants at Longacre, Harewood, Carbondale, Mammoth, Cedar Grove and Shrewsberry.

Major James H. Allport, for many years prominently identified with the development of coal lands in the Barnesboro region of central Pennsylvania, has become connected with the Clinchfield Coal Corporation, of Dante, W. Va., in an important capacity. Major Allport will not give up his Barnesboro residence at present, but will devote most of his time to the West Virginia concern.

F. William Hausmann, for the past six years chief mechanical engineer for the Sloss-Sheffield Steel and Iron Co., of Birmingham, Ala., has recently resigned from this position. Mr. Hausmann, as mechanical engineer for all the coal and ore properties of the Sloss-Sheffield company, has inaugurated a number of important improvements, and has many friends in the Birmingham district.

Obituary

John Carver, aged 65, one of the pioneer coal operators of the Kanawha Valley and brother of Enoch Carver, died recently at his home in Charleston, W. Va. Mr. Carver's health had been failing for some time. He was associated with the firm of Carver Brothers until about a year ago, when this concern became financially involved. Mr. Carver came to America from England in 1864. He is survived by a wife and eight children.

Construction News

Birmingham, Ala. The Stith Coal Co., of Birmingham, contemplates the construction of a coal-washing plant.

The Gas Light Coal & Coke Co. contemplate building a coal washer.

Seattle, Wash. The Poulson Coal Co. will erect coal bunkers on the water front, Bellingham Bay, Wash. Harry Yarrow and former State Senator Poulson control the properties.

Middlesboro, Ky. The Nicholson Coal Co. has increased its capital stock from $60,000 to $120,000 and will spend $15,000 on the installation of a coal-washing plant and other equipment.

Duluth, Minn. The contract for construction work on the first section of the Island Creek Coal Co.'s new dock has been awarded to Whitney Bros., of Superior, Wis. The estimated cost is $600,000.

Saginaw, Mich. The Roberts & Schaeffer Co., Chicago, Ill., is preparing plans for new coal docks to be built at Saginaw for the Pere Marquette R.R. Estimated cost, $25,000. A. R. Merrick is superintendent.

The Pacific Coast Coal Co. will erect a $250,000 plant for the manufacture of coal briquets near Renton, Wash. Plant is to have a capacity of 400 tons per day. Plans are being prepared by James Anderson, engineer for the company.

Block, Tenn. The Tennessee Jellico Coal Co., which has recently acquired the property of the Block Coal & Coke Co. will, during the summer, complete the tipple and washer at Block, increasing the daily output to 1000 tons. Robert Wedekind, Louisville, Ky., is president.

Waverly, Ky.—The Alabama Coal & Coke Co., which recently purchased the Drury Coal Co.'s properties near here, will install new boilers, pumps and coal-cutting machinery and will build additional houses, remodel and repair the tipple, etc. R. M. Auxford, Birmingham, Ala., is general manager.

Charleston, W. Va. The Sunday Creek Coal Co. is preparing to build a power plant at its Longacre property, to take the place of one that was recently destroyed by fire. The new plant will be much more extensive and complete than the one destroyed. C. E. Fukes, Columbus, Ohio, is chief engineer.

Hinton, W. Va. The West Virginia Power Co., recently organized with $5,000,000 capital stock, is reported to contemplate the construction of a hydro-electric power plant at the Sandstone Falls of New River, west of Hinton. Paul T. Brady, of New York, and Fred Auld, of Charleston, W. Va., are among the incorporators.

Publications Received

THIRTEENTH ANNUAL REPORT OF THE MINING INDUSTRY OF IDAHO for 1911. By Robert N. Bell, state inspector of mines. 134 pages, 6x9 inches, illustrated.

THIRTY-SECOND ANNUAL REPORT OF THE DIRECTOR OF THE U. S. GEOLOGICAL SURVEY for the year ending June 30, 1911. By George Otis Smith, director. 145 pages, 6x9 inches, 2 plates. Government Printing Office, Washington, D. C.

QUARTERLY OF THE COLORADO SCHOOL OF MINES for January, 1912. 30 pages, 6x9 inches.

This number contains the proceedings of the Colorado Mining and Metallurgical Association at the mass meeting held in the House of Representatives, Denver, Dec. 28, 1911.

JOURNAL OF THE WESTERN SOCIETY OF ENGINEERS, February, 1912. 200 pages, 6x9 inches, illustrated. 50c., office of the society, Chicago.

The papers presented in this issue are: "Notes on Structural Steel Designs," by Albert Reichmann; "The Use of the Great Lakes," by Robert R. McCormick; and an article on the "Going Value" of business enterprises, by Frank F. Fowle.

Trade Publications

Ingersoll-Rand Co., 11 Broadway, New York. Leaflet, Form 4111. Type BC hammer drills. Illustrated, 16 pages, 6x9 in.

Goulds Manufacturing Co., Seneca Falls, N. Y. Booklet. Triplex power pumps. Illustrated, 16 pages, 6¾x8¼ in.

Stromberg-Carlson Telephone Manufacturing Co., Rochester, N. Y. Booklet No. 290. Private telephone systems. Illustrated, 20 pages, 3½x6 in.

Allen & Garcia Co., McCormick Building, Chicago, Ill. Attractive booklet describing and illustrating consulting and construction work executed by this firm of engineers: Coal mining plants, bridges, coal-washing plants, factory buildings, etc. 20 pages, 6¼x9½ in.

Industrial Notes

The Pennsylvania Storage Battery Co., of Philadelphia, Penn., manufacturer of an electric lamp for miners, has removed to a larger plant, at Nos. 221-227 North Twenty-third St.

The Ruggles-Coles Engineering Co., 50 Church St., New York City, recently received from the Toltec Portland Cement Co., Mexico, an order for one of their Class A-10 machines. This is the third dryer of this class ordered by this concern, the two they now have being used for drying coal.

The Goulds Manufacturing Co., Seneca Falls, N. Y., announces that at the annual meeting of the board of directors, Feb. 26, all the officers who served during the past year were reëlected. The annual report on the business of the company showed a slight increase over the preceding year in both the gross amount of sales and net profits.

The Metropolitan Coal Co., of Boston, Mass., is to abandan its present yard in Chelsea, Mass., and will occupy new and larger quarters on Broadway of the same city. This new coal-handling plant which, with its equipment, will cost in the neighborhood of $100,000, is being designed by Monks & Johnson, architects and engineers, 7 Water St., Boston, Mass.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The coal market has experienced an activity during the past week verging on a panic. Another touch of cold weather, in addition to the possibility of labor troubles, has developed an almost unprecedented demand at some of the largest distributing centers in the East. The requisitions for spot fuel have been so urgent that there is a strong probability of a sensational advance in prices, should the situation continue unrelieved.

The shortage is most acute at seaboard points and is being further aggravated by transatlantic steamers coaling for the round trip because of the strike in Great Britain. The larger buyers in the market are seeking to cover their requirements through May. In anthracite the consumption for February was the largest in years, and all possible receipts for the current month are already covered; supplies are fair at some points, but no additional stocks are accumulating.

In the Pittsburg district the car situation is much improved and the mines are working up to 80 or 90 per cent. of their full rated capacity; the demand is urgent and any coal available for Eastern shipment commands almost unprecedented figures. At other points, particularly in northern New York, Canada and in through Ohio, the railroad congestion is still acutely evident, with no prospects for immediate relief; the Ohio mines are only working from 35 to 50 per cent. of normal. Some recession in prices has occurred in the South, but the trade continues brisk. There are many inquiries for April tonnages, but the operators are refusing to quote beyond Apr. 15.

The market in the Middle West is extremely erratic, prices fluctuating rapidly and over a wide range. The dealers believe they have sufficient coal *en route* on cars, while the shippers claim much of this is being confiscated by the railroads, some of whom are dumping coal on the right-of-way for storage purposes.

Another fall in temperature has caused some activity in the Far West.

Boston, Mass.

The principal change in the situation here is the demand from transatlantic companies for bunker coal to make the round trip. This marks a further depletion of stocks already short, and shippers of bituminous may well wonder where supplies are to come from in sufficient volume. Prices for spot coal are therefore somewhat firmer, although no pronounced lift over last week can yet be reported. The larger buyers are seeking to cover their requirements for May, and in order to be safe for April are buying spot coal at high prices. Occasional rumors are heard of contracts being placed for the entire year, but as yet there is no general move in that direction. Meanwhile the current market is active and likely to become more so.

The trustees of the Boston City Hospital closed for 3000 tons of New River lately, one cargo each of 1000 tons for March, April and June, at $4.90 alongside the wharf. At $1.25 freights this would net $2.75, f.o.b. Newport News. Water rates today are strong at $1.25, and for 1500-ton barges $1.35 is asked below bridges. To Providence and other Sound ports, $1.25 has been paid.

The higher grades of Pennsylvania coal remain out of the market, and others that are available are steadily advancing in price. Of these there are relatively only small amounts at either New York or Philadelphia.

Supplies of anthracite are not gaining any, and all the dealers are anxious over shipments due or promised. It will take a large March tonnage to give Eastern dealers, not any surplus, but enough to keep them going.

Wholesale prices are as follows:

Clearfield, for shipment, f.o.b. mines	$1.65@2.00
Somerset, for shipment, f.o.b. mines	1.80@2.00
Pocahontas, New River, f.o.b. Hampton Roads	3.25@3.40
Pocahontas, New River, Boston, on cars	5.00
Pocahontas, New River, Providence, on cars	4.90@5.10

New York

The bituminous situation here at New York has hardened during the present week to an unusual extent. The supply of coal at the piers is shorter than in years, and buying by shippers who are short on their contracts has caused an advance in prices until even coals of unknown quality are being held at $3.65, f.o.b. piers, which is equivalent to $2 at the mines. These are the grades of coals that ordinarily do not find a ready market on a basis of 80c. at the mines. Demand is unusually heavy, both spot and contract, and shippers are having all they can do to satisfy contract obligations.

As is usually the case where there is such a heavy demand, coal business is being hampered by a short car supply and slow movement on the railroads, which tends to aggravate the situation and make the present shortage keener.

The strike in England has had a marked influence on the coal business here. The additional demands from abroad have caused consumers added uneasiness about the labor situation, and the efforts of coal buyers to accumulate stocks amount to almost a panic.

Philadelphia, Penn.

Added impetus was given to the retail trade by a snow storm last week. The impression that winter was still with us, in addition to the uncertainty of the labor situation, has again started an increased flow of orders toward the dealers. The situation, locally, had eased up somewhat on egg and chestnut sizes, they being in better supply, but the reminder that more cold weather might be expected, has had the effect of making them again active.

From a careful survey of the situation in this locality, it appears that few, if any, of the dealers have been able to accumulate any stocks whatever. Of course, some of the yards have considerable coal in them, notably the large ones, but any cessation in fresh supplies would soon reduce these to a minimum. As far as the prepared sizes and pea are concerned, none of the dealers report any going into stock for the future, all of these going out as fast as new coal comes in. The month of February has perhaps been one of the most favorable in the history of the trade in this vicinity. Almost to a unit, the yards have been going at full blast for the entire month, which is quite unusual, and so far in March there is not the slightest indication of a cessation.

Pittsburg

Bituminous—The output of coal is now limited only by the transportation facilities, all mines in the district operating as full as the car supply will admit. There is a little stocking of coal at mines, but as a rule, not much. Mines are operating on an average of between 80 and 90 per cent. of the full rated capacity. The car supply is fair, being almost satisfactory at many mines, and in no districts is it materially below what would be sufficient in times of normal demand. Consumers have thus far stocked relatively little coal, having been deterred at first by general business uncertainties and later by the advance in prices. The railroads have been stocking

coal very freely. Slack is decidedly scarcer than screened coal.

Greensburg district coal has sold as high as $1.60 and Clearfield at $1.70. Some brokers have standing orders to purchase everything available at $1.50 because of the urgent demand in the East. We quote: Nut, $1.20@1.30; mine-run, $1.25@1.35; ¾-in., $1.35@1.45; 1¼-in., $1.50@1.60; slack, $1@1.10 per ton at mine, Pittsburg district.

Connellsville Coke—Spot furnace coke has moved up about 5c. per ton in the past week, due to continued demand for a moderate tonnage, while there is practically no surplus available. The demand has been from brokers and operators, short on their contracts, more than from consumers. No interest has been manifested in contract coke. We advance prices on prompt furnace 5c. per ton and on prompt foundry 5c. to 10c. per ton: Prompt furnace, $1.85@1.95; contract furnace, $1.80@1.90; prompt foundry, $2.25@2.40; contract foundry, $2.20@2.40 per ton at ovens.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Feb. 24 at 391,253 tons, a decrease of 2000 tons, and shipments at 4505 cars to Pittsburg, 5248 cars to points West and 985 cars to points East, a total of 11,735 cars, a decrease of 100.

Baltimore, Md.

A somewhat sensational rise in prices of practically all grades of bituminous coal took place in the Baltimore market during the past week. The low grade bituminous product which the trade has heretofore been only too willing to sell at prices ranging from 90c. to $1.10 per ton, has been selling during the week for $1.50, with consumers eager to purchase. The next best grade brought about $1.60 per ton, while the Big Vein Georges Creek coal sold at not less than $1.30, and was scarce at that figure. The market was the most favorable from the standpoint of prices and demand that the trade in Baltimore has known for some time.

Buffalo, N. Y.

Coal shipments continue to be held up on most of the railroads about as badly as a week or two ago, and there is not likely to be much relief until warmer weather appears. The Canadian roads are in particularly bad shape, and consumers in the Dominion are finding deliveries much delayed. There is not much talk of actual distress among consumers, but their supplies in some instances are near the vanishing point.

The most trouble for several weeks has been in northern New York, as supplies in that section are growing quite small. Deliveries from the mines in the bituminous district have been held up for weeks on sidings a long way from their destination. Cars have been piling up at Dewitt, on the New York Central, and equipment appears to be insufficient to handle them.

Prices have been holding with great firmness on spot coal, and there is not much to be had, the difficulty being to keep the customers supplied on old orders. Salesmen are not making much effort to land new business, and in some instances have been called in from the road. Pittsburg quotations are $2.60 for three-quarter, $2.50 for mine-run and $2.25 for slack, with Allegheny Valley about 30c. less. Coke remains firm at $4.25 for the best Connellsville foundry and $3.50 for stock.

Cleveland, Ohio

Conditions in the past week and up to the present writing, are worse than they were the week previous, owing to the continued shortage of cars. A great many of the mines in the Ohio fields have been closed down on account of this, and those that are working are only running about 35% of their capacity, 20% of which is absorbed by the railroads.

In the Cleveland market today, however, there are not over a dozen cars of coal of all kinds on track, where under normal conditions there should be from 300 to 400. Prices in consequence on all grades have increased from 20 to 30c. per ton, in fact it is not a case of price at all with parties requiring the coal. Reports are that a number of factories in Cleveland and the vicinity have been reducing their output and discharging men, and that a number have closed down altogether. The general impression among coal dealers is that conditions will become very serious in the near future.

Columbus, Ohio

Demoralization on all railroads leading from the Ohio coal fields and especially congestion at junction points have not been relieved and as a result the coal traffic during the past week was cut down to a small percentage of the usual figures. Suffering still continues in Michigan where many schools were compelled to dismiss, and practically all of the manufacturing establishments in many parts of Michigan have been compelled to close down.

Prices are still firm in every variety and district. Operators and jobbers do not anticipate any decline and it is generally believed that quotations will rule high from this time on. While the circular has not been advanced, premium coal is now the rule and any spot fuel will bring considerably more than the circular figures.

As a result of the transportation troubles it is almost impossible for railroads to get the empties back to the mines and the production in all the Ohio fields has been quite low. It is estimated that between 35 and 50 per cent. of normal will cover the output. Some of the sections are selling quite a tonnage of railroad fuel.

Retail trade has been good despite the warmer weather. Many of the domestic consumers were compelled to make their second orders as their supply was exhausted. The usual winter prices are prevailing in the domestic trade.

Prices in Ohio fields are as follows:

Hocking Valley	
Domestic lump	$1.60
¾-in.	1.40
Mine-run	1.15
Nut	1.20
Pea and slack	0.85
Coarse slack	0.75
Pittsburg No. 8	
¾-in.	1.15
Mine-run	1.05
Coarse slack	0.90
Pomeroy Bend	
Domestic lump	1.75
¾-in.	1.50
Nut	1.50
Mine-run	1.25
Small sizes	1.00

Hampton Roads, Va.

With the price of spot coal at Hampton Roads advanced to $3.50 yesterday, an increase of 80c. in two days, it is the opinion of a number of local coal men that the price will go to a high figure should the strike in England continue for any length of time. Four steamers have been chartered by the British Admiralty to load coal here, the charter calling for Gibraltar, but it is likely that they will be sent to another port from there, the freight rate being $4.80. One or more of the steamers are expected here this week, the ships under charter being the British steamers "Bleamoor," 2403 tons; "Corby," 2280 tons; "Kassala," 2498 tons, and "Teespool," 2938 tons.

An agent of one of the local companies said he had been approached by representatives of the Italian government for prices. He has furnished samples of coal and claims the prospects look good for a large shipment to that country. Representatives from Brazil have also been making inquiries regarding the price of coal from this port and it is likely that considerable business will be done with South America if the strike continues.

Coming as it does, when the coal operators shipping from here are swamped with orders and handicapped by lack of cars, the strike has caught the local shippers in a bad way. The price of coal on contract has not advanced any, nor will it, according to the local agents, but that spot coal would perhaps advance to $7 or $8 a ton in 60 days, should the strike in England continue, seems reasonable to believe.

It seems to be the prevailing opinion among the coal men, however, that the English government will bring the operators and miners to terms and the matter be settled before it reaches large proportions.

Louisville, Ky.

In a few instances retail coal dealers are advertising reductions in the price of coal despite the fact that March promises to more than retain its record for winter temperatures. Kentucky lump is being advertised at $2.75 a load; Kentucky nut at $2.65; Jellico lump, $3.40; Pocahontas, $3.25; Jellico nut and slack, $2; Straight Creek lump, $3.25.

These prices do not stipulate a 2000-lb. ton, however, and as a rule the dealers are holding, as yet, to their old prices. A number of them advertise the fact that they did not increase prices during the severe winter, now passing, and in this respect Louisville certainly made an enviable record.

Nashville, Tenn.

This section of the South is still experiencing good coal-selling weather, and the demand continues unusually brisk for this time of the year. Quite a good deal of coal has been sold during the past week in the West Kentucky field, for deliveries commencing Apr. 1, at good prices. It looks as though the nonunion field will certainly reap a rich harvest in event of a strike.

Up to the present time little railroad coal is being stored in this territory, but there are many inquiries for heavy tonnages in April, while few of the operators are inclined to quote for delivery after Apr. 15. Quite a good deal of coal has been booked for the first two weeks in April. Although there is still a good demand for screenings, on account of better car service during the past week, and plenty of domestic coal being mined, the situation has eased off considerably.

Indianapolis

The operation of several mines along the rivers and low lands was considerably interfered with by high water during the past week. Some mines were closed for a few days during the earlier part of the week, owing to the heavy snow, the miners not being able to get to the mines.

The demand for coal is good and the mines have orders booked to keep them busy on full time for several months.

Chicago

There has been a slight slump in domestic, while the price of steam coal remains unchanged. A lot of coal held out by the railroads has arrived on the market with a resultant weakening of some prices.

On the other hand, a continuation of buying for storage purposes has strengthened the market in other directions. Franklin County coal, which was selling several days ago at $2.25, wholesale, is now being disposed of at $2 and $1.75. The screenings market has advanced about 5c. a ton while some weakness has developed in anthracite. The price for Pocahontas mine-run is firm at $1.25 or better with occasional sales at $1.35. Coke is strong, Connellsville and Wise County being scarce; the market for the latter shows a 10c. advance. Hocking Valley coal has been slow in arriving at the market.

Prevailing prices at Chicago are as follows:

Sullivan County:	
Domestic lump	$2.62
Egg	2.62
Steam lump	$2.37@2.57
Screenings	1.97@2.07
Springfield:	
Domestic lump	$3.05
Steam lump	$2.32@2.42
Mine-run	2.07@2.17
Screenings	1.87@1.97
Clinton:	
Domestic lump	$2.57
Steam lump	$2.32@2.42
Mine-run	2.17@2.27
Screenings	1.87@2.00
Pocahontas and New River:	
Mine-run	$3.25@3.55
Lump and egg	4.20@4.30

Coke—Prices asked for coke are: Connellsville and Wise County, $4.85; byproduct, egg and stove, $4.95; byproduct, nut, $4.75; gas house, $4.90@5.

Minneapolis—St. Paul

Wholesale men say there has been a slowing up in the demand from the Northwest as the dealer refuses to stock up in anticipation of the much talked of strike. Retail merchants claim they have coal *en route* and figure that by the time deliveries are made on orders placed now there will be no market for the product and they will have to carry it over. Wholesalers argue that they should not bank too much on these shipments as the railroads are confiscating large quantities of coal for their own use and will continue to do so more freely from now on.

The steam users and retailers are laying in very little coal for storage purposes. The fact that during previous strike periods the docks at the head of the lakes have always been able to furnish supplies leads them to think that no matter what happens they will be able to get sufficient coal. This year they may find things different if the labor troubles continue very long, as stocks on the docks will most likely be cleaned up by Apr. 1. Prices at the docks on bituminous coals are reported to be at circular. Screenings are scarce and only small quantities can be had here and there. Southern Illinois coal is selling all the way from $1.75 up to $2.50.

St. Louis, Mo.

The St. Louis market is in a very unsettled condition. One day the demand will be exceedingly good and the next the supply will exceed the demand to such an extent that there will be a dropping off from 15 to 25c. per ton. The later part of each of the past two weeks a heavy snow set in, tying up the railroads for a day or two and pushing the Standard prices out of sight. It also stimulated the market to some extent on the other coals, but as soon as the weather moderated, prices went off again.

The railroads are still buying heavily, with the exception of the Frisco, which did not start until Monday of this week. The Illinois Central, it is understood, has purchased the output of approximately one-fourth of the mines on the St. Louis division, and this coal is being stored on the right-of-way. It is understood that the Burlington has bought in the neighborhood of 500 cars of Standard coal and also 300 of Eastern coals. There is some storing in the manufacturing lines in St. Louis and outside, but not to the extent that has been anticipated. Indications are that the market, both Standard and high grade, will grow stronger unless weather conditions are abnormally warm.

The high-grade coals from the inner district are bringing $1.25 and are in good demand; anthracite is moving fairly well at the current circular. Eastern smokeless is coming in slowly, but is in good demand, and gas-house and byproduct coke is moving freely at the prevailing circular of $4.75, St. Louis.

An approximate quotation of prices is as follows:

Franklin County	
Lump and egg	$1.75@1.85
No. 1 nut	1.70@1.85
No. 2 nut	1.60@1.75
No. 3 nut	1.35@1.40
2-in. screenings	1.10@1.20
Carterville	
Lump and egg	$1.70@1.85
No. 1 nut	1.60@1.70
No. 2 nut	1.50@1.60
No. 3 nut	1.30@1.40
Screenings	1.10@1.20
Mine-run	1.30@1.40
No. 1 washed	1.60@1.75
No. 2 washed	1.40@1.50
No. 3 washed	1.30@1.40
No. 4 washed	1.20@1.25
No. 5 washed	0.75@0.90
Standard	
6-in. lump	$1.75@1.80
2-in. lump	1.50@1.65
Screenings	1.05@1.15
Mt. Olive	
6-in. lump	$1.75
3-in. lump	1.75
2x6-in. egg	1.50
No. 1 nut	1.30

Salt Lake City, Utah

The past week has seen a brisk demand for coal, owing to a renewal of cold weather. Beginning Mar. 1, Wyoming coal is being sold in the Salt Lake market at the same price as the Utah; heretofore, Wyoming coal has demanded a slightly increased price.

Among the coal dealers there is great interest in the development of a big deal in Emery County coal properties by William G. Sharp, president of the United States Smelting, Refining and Mining Co., and Thomas Davis, of the Davis coal interests of West Virginia.

Mine prices are: Lump, $2.45; nut, $2.25; slack, $1.50.

Portland, Ore.

One cargo of Australian coal arrived here a few days ago from Newcastle, and the vessel is now at Astoria discharging part of it. The remainder will be brought to Portland. There is already an over-supply of Australian coal here, and this will probably have to be carried over for next season. Another cargo, due to arrive here in March, will be diverted to Puget Sound.

The demand for coal in this section will not be heavy until the wood supply runs low, or the opening of the Panama Canal, when there will be a demand for bunker coal; it is almost certain that a number of steamship lines will be established to ply between Pacific Coast ports and Europe.

San Francisco, Calif.

Last year foreign coal imports here aggregated 343,525 tons, of which 193,890 were from British Columbia and 149,635 from Australia.

The main source of the coke supply is Belgium and England and the imports for 1911 were 20,000 tons from the former and 15,000 from the latter, these figures include foundry, smelting and gas-house cokes. Owing to a sharp advance in freight rates, spot prices and for forward delivery are high, about $13 to $13.50 for foundry and $11 for gas house.

This winter has been marked with typical Californian weather and the movement of coal has been sluggish. Stocks on hand, while not large, are accumulating, but with the undoubted influx of people who will come here to participate in the building of the World's Fair in 1915, the coal merchants have every confidence in the future.

Current prices in the trade are as follows per long ton:

Wellington, British Columbia	$8.00
Pelau Main, Australia	8.00
American Cannel	8.15
Rock Springs	9.00
Cumberland	12.50
Peacock (Rock Springs)	7.90

Production and Transportation Statistics

Erratum

In the table of shipments over the Norfolk & Western Ry. for the months of January, 1911-12, appearing in Coal Age, Vol. 1, p. 662, the headings "1911" and "1912" should be reversed.

Baltimore & Ohio R.R.

Shipments of coal and coke over the lines of the B. & O. R.R. for the months of January, 1911-12, were as follows:

	1911	1912
Coal	2,352,240	2,443,528
Coke	271,217	329,556
Total	2,623,457	2,773,084

Imports

Imports of bituminous coal into the United States for January were 124,788 tons, valued at $349,709 as compared with 144,457 tons valued at $401,147 for the same month last year.

Exports

Comparative statement of fuel exports for January, 1911-12, is as follows:

	1911	1912
Bituminous	740,974	667,263
Anthracite	251,737	221,854
Coke	87,578	53,114
Bunker coal	481,874	552,965
Total	1,562,163	1,495,196

Island Creek Coal Co.

Severe winter weather has cut down production for the last two months. January output was about 125,000 tons and February was 145,000 tons. This is 80,000 to 90,000 tons less than the normal output for those months, had weather troubles been less acute.

Foreign Markets

France

The French imports and exports of coal for the year 1911 were as follows:

Imports

From	1911	1910
Coal		
Great Britain	9,099,265	8,470,527
Belgium	3,910,824	4,052,045
Germany	2,994,297	2,156,726
Other countries	226,317	227,965
Totals	16,230,703	14,907,263
Coke		
Belgium	482,655	495,610
Germany	1,787,853	1,737,645
Other countries	48,993	30,839
Totals	2,319,501	2,264,094
Briquettes		
Great Britain	121,989	121,006
Belgium	790,957	671,828
Germany	189,390	109,315
Other countries	86,990	72,366
Totals	1,189,326	974,515

Exports

	1911	1910
Coal	1,335,195	1,278,698
Coke	184,416	168,977
Briquettes	114,495	131,457
Totals	1,634,106	1,578,132

Egypt

Imports of coal into Egypt for the year 1911 were 1,581,620 tons, showing an increase over the year previous of 208,485 tons.

Great Britain

Coal is practically unobtainable on the market today, and in consequence business is at a standstill. Quotations for both large and small steams are purely nominal, as follows:

Best Welsh steam coal	$4.68@4.80
Seconds	4.32@4.44
Thirds	4.08@4.14
Best dry coals	4.50@4.62
Best Monmouthshire	4.20@4.26
Seconds	3.96@4.02
Best Cardiff small coals	3.42@3.54
Seconds	3.12@3.24

The prices for Cardiff coals are all f.o.b. Cardiff, Penarth, or Barry, while those of Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage, and for cash in 30 days—less 2½% discount.

Spain

Comparative statement of Spanish fuel imports, practically all from England, for the years 1910-11 is:

	1910	1911
Coal	2,021,116	2,055,468
Coke	294,158	316,448

Russia

Coal production of the Donetz Basin for the year 1911 was 16,380,000 metric tons, an increase of 7% over that for the year previous. Of the total 4,553,640 tons were destined for the use of railways, 3,701,880 tons were consumed by metallurgical works, 982,800 by sugar works, 7,108,920 by other consumers. and 32,760 tons were exported.

Financial Notes

A $15,000,000 company, backed by English capital, is being formed for development of Warrior coal fields near Birmingham, Alabama.

The earnings of the Philadelphia & Reading Coal & Iron Co. in January were so large that it is believed the officers expect a coal strike. The gross earnings of the coal company for the month showed an increase of $719,220, or about 17 per cent.; net earnings increased $243,888.

The International Coal & Coke Co. was closed from April to November last year on account of labor troubles, but since November it has been adding to the output until at present it is about 1000 tons a day. Expectations of a resumption to the 6% dividends is supposed to be back of the demand for the company's stock, in which the trade is active.

There are reports abroad that the Colorado Fuel & Iron Co. directors are planning to make a payment on the preferred stock of some of the accumulated dividends. On the $2,000,000 8 per cent. preferred stock that is outstanding the company owes something like $1,480,000, or 74 per cent. What seems to support the reports is the fact that the company's charter expires in October. It is said that before it can be renewed the indebtedness on the preferred stock must be paid off. Likewise, the preferred stock is selling around 115. Though dividends have not been paid since 1903, the company earned 62.98 per cent. on the preferred last year and in 1910 it earned 75.34 per cent. on the preferred.

The committee of the directors of the Sheffield Coal & Iron Co. appointed by the executive committee in November to work out a plan for the relief of the company's properties, some of which have lain idle since November, 1910, sent out a circular to stockholders recently giving balance sheets as of May 1, 1909, when the company in its present form began business, and of Jan. 2, 1912. There is a decrease in assets of $112,595 in the period. An accompanying statement of resources and their application shows for the period, losses on operations totaling $245,793. It was the default in the payment of $63,580 January interest on the first mortgage bonds and the approaching maturity of $82,000 of the company's notes on Apr. 1 which has brought matters to a crisis.

Deliver Clean, Unbroken Coal

To meet the present demand for clean, unbroken coal, the "Link-Belt" arrangement of Loading Boom and Picking Table has proved to be the most effective means of reducing breakage and delivering coal free from foreign matter.

As shown in the illustration, the coal is received from end of Shaking Screen and delivered to railroad cars with practically no breakage, as it is lowered—not dropped—to the bottom of the car.

Let our experienced engineers give you some practical suggestions for reducing the breakage of your coal to a minimum.

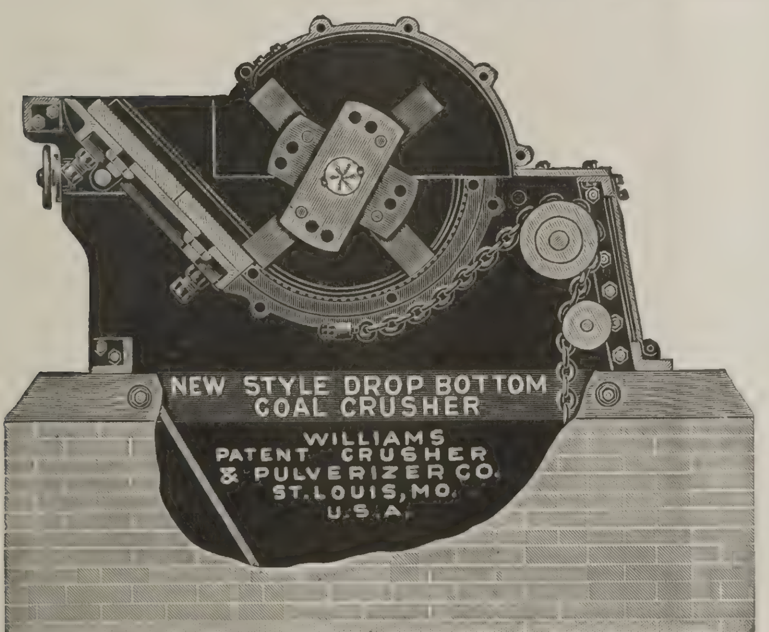
A Better Method of Crushing And Its Better Results

Williams Coal Crushers



THE METHOD. The Hinged Hammer method of Coal Crushing is a succession of rapid impact blows caused by centrifugal action and heightened by the flexibility of the hammers which, with each revolution, strike the material between the points of the revolving body and the breaker plates and cage. The cage is the stationary grinding surface. Every other method of crushing is a constant rubbing between the grinding parts which creates friction and uses up power. In Williams Crushers every wearing part is adjustable to itself, to wear, and to every other wearing part.

THE RESULTS. Williams Patent Hinged Hammer Coal Crushers can crush more coal with less power and lower cost of maintenance than any other crusher on the market—and because of the feature of adjustability, the product is always uniform. That is why there are more than 2,000 in daily use. Our Catalog No. 5 gives full information. Write for it.

Manufactured and Licensed Under 87 Separate and Distinct Patents.

The Williams Patent Crusher & Pulverizer Company

Old Colony Building, Chicago

347 Monadnock Bldg., San Francisco, Cal.

Factory: 2701 No. Broadway, St. Louis.

POSITIONS VACANT

Advertisements under this heading 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Wanted—An experienced mine electrician who can wind armatures and keep in thorough repair, a half dozen direct current generators, a dozen locomotives, and several motors located at different mines; salary $100 per month; location a plain mining camp, on short branch in central West Virginia. Wanted, by same company, a superintendent-foreman for small mine having an output of 400 tons per day, man who can survey preferred; state age, experience fully, where obtained, in what positions, education and where obtained, married or single, teetotaler or otherwise, and salary expected. Address Box 16, Coal Age. Mar. 9.

SITUATIONS WANTED

Advertisements under this head 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Position wanted as mining engineer by young man, 25 years of age; technical education; five years' experience as engineer of mines in operation and construction of new mining plants in the bituminous coal field; open for engagement April 1. Address Box 15, Coal Age. Mar. 9.

Commissary man wants position; if you have an opening for a store manager, write to the National Commissary Managers Association, 801 Manhattan Building, Chicago; good men will be recommended without charge; inquiries treated confidentially if desired. Mar. 23.

Experienced store manager desires to make a change; has made good record; will furnish best references. Address Box 14, Coal Age. Mar. 23.

Moments with the Advertising Editor

A Department for Subscribers Conducted by the Service Department of Coal Age

No good paper is owned by its advertisers. The readers hold title—free, clear, paid-up and no assessments beyond the subscription price.

And this is as it should be—and often is not.

Because there are certain classes of advertisers who seem to think that payment for space in the advertising pages entitles them to the use of the reading columns, and to dictate the policy of the paper, the color of the cover, the cut of the editor's clothes and the nature of his religion.

And there are some publications weak-kneed enough to fall for this sort of dictatorial policy on the part of big advertisers, with the result that the paper loses its greatest asset—the confidence of its readers.

And with the loss of the readers' confidence goes the value of the paper to advertisers.

No useful engineering paper can be established and prosper long that is not published first, last and all the time for the reader, that is not helpful to him, honest with him, showing him how to better his work or his condition. One that will take the side of a reader as against its best advertiser when the reader's interest is at stake.

And this is the principle upon which Coal Age is published—and we want readers to know that such is a *principle* with us and not a "happen chance."

We say that the confidence of readers is not to be trifled with, and that the placing in the reading columns of manufacturers' cuts and fulsome praise of their output is trifling with the reader and belittling his intelligence. Is it interesting and informative, is it new and news?—that is the measure which must decide, and the editors must be the judges and writers and the paper must make and pay for the cuts.

And Coal Age does these things, not because it likes to spend money, but because it knows that it is the best thing to do.

Every "house organ," every catalog, every circular holds a brief for the fellow who publishes it—and that is natural, and fair enough when the advertising is naked and not disguised in false whiskers and green goggles.

You accept the statements of manufacturers only after you have sifted and weighed their claims.

You look upon the editorial statements as authoritative because you know that the editors aim to make them such, and that they have the resources and knowledge necessary.

And so the good paper, the worth while paper, draws the sharp line between its reading and advertising pages and says, "Thus far and no farther."

If this sounds like a reflection upon the advertising pages it is poor shooting. We're proud of them.

We know that no technical paper carries a better lot of advertising, and none has better concerns represented. We know that, as a rule, the advertising is interesting and informative.

We believe that every advertiser has grasped and applied the fundamental principle of profitable advertising—sincerity and truth.

We have confidence in our advertisers and want our readers to share it.

But advertising in this paper must be done in the name of advertising, and not try to sneak in at the back door.

Then the readers win—they know where they're at; the advertisers win—they share the readers' confidence. The paper wins—its stand is recognized and appreciated.

And *that* is a trinity, close-knit, that carries no such word as failure in its lexicon.

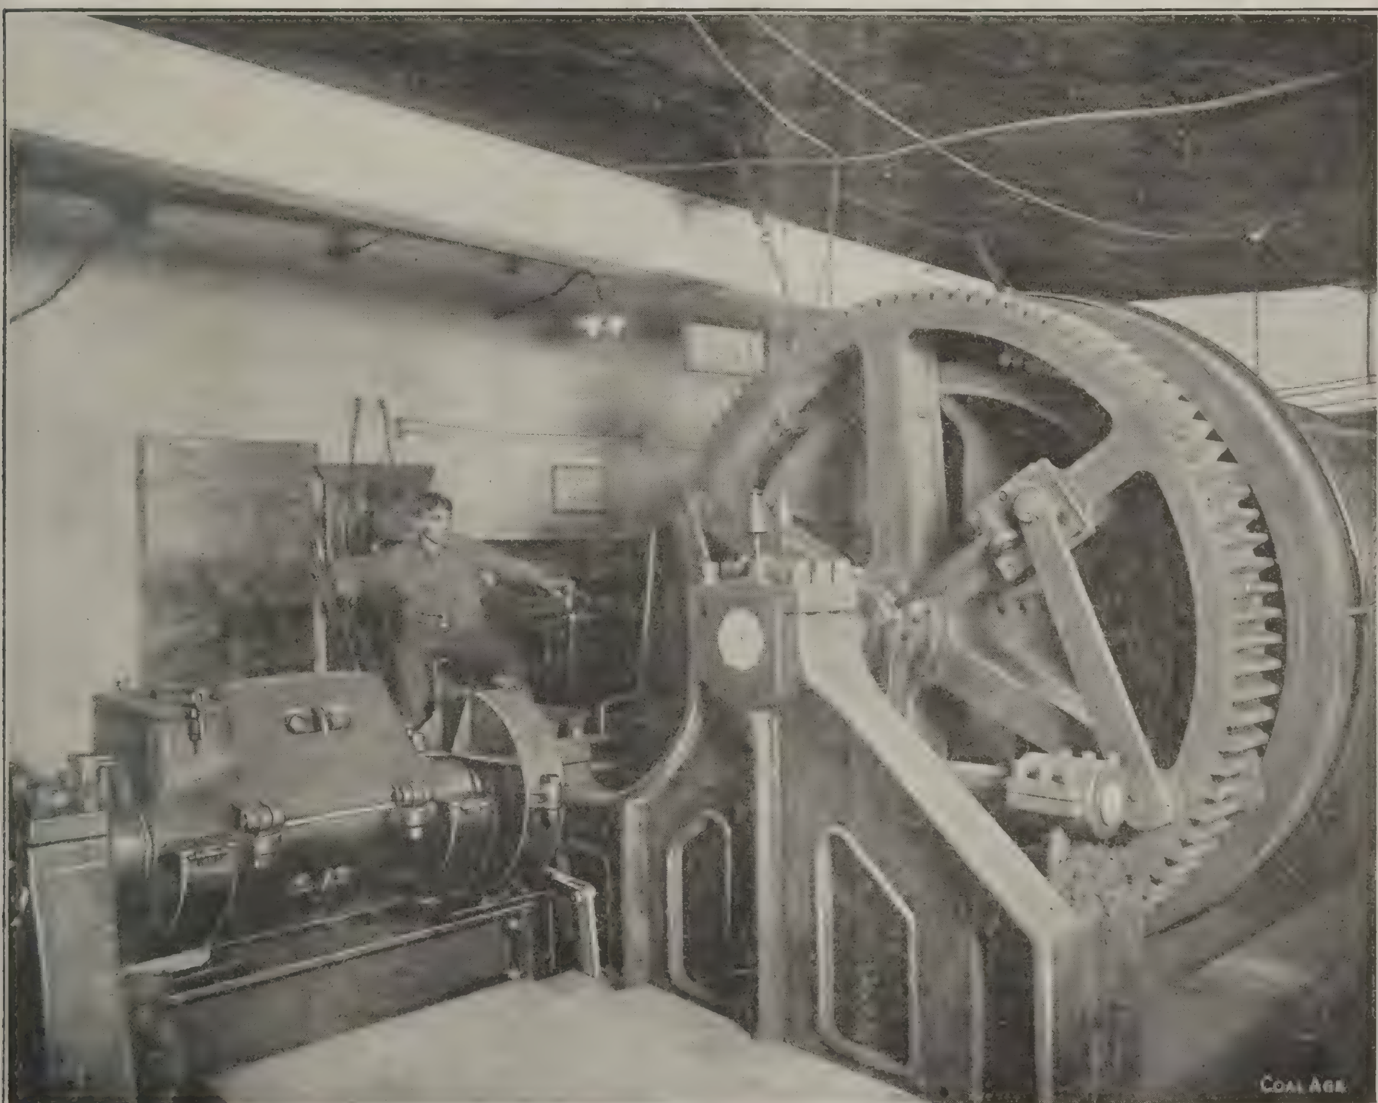
COAL AGE

Devoted to Coal Mining and Coke Manufacture

Volume 1, No. 23.
Issued Every Saturday.
Hill Publishing Company.

NEW YORK, MARCH 16, 1912

Ten Cents per Copy.
U. S. and Mexico, $3 per Year.
Canada, $4; Other Countries, $5.



An Electrically Driven Slope Hoist in the East Cooper Workings of the D. L. & W. Company's Woodward Mine, Kingston, Penn.

This hoist handles 5-car trips at a speed of 500 ft. per min. It is equipped with a 6-ft. diameter drum, which winds 3600 ft. of 1-in. rope, and is driven by two 80-hp., 500 volt, totally incased motors. A clutch drive and band brake permit the length of haul to be adjusted, and a load to be lowered, without operating the motors. The motor casing forms a guard for the transmission gears as well as a protection for the electrical parts. This installation illustrates the application of an electric drive to an equipment formerly operated by steam power.

COAL AGE

Vol. 1 NEW YORK, MARCH 16, 1912 No. 23

THE anthracite mines in Pennsylvania are practically the only important collieries in the world that are operated under a system where the state inspectors are selected by popular vote instead of appointment. The latter plan was abolished in 1901 when the Pennsylvania Legislature amended the anthracite law in compliance with the demands of the miners.

The present statutes, like those formerly in force, provide that no man is eligible to serve as an inspector until he has answered ninety per cent. of the questions propounded at a specially authorized examination. Nominations for party election, therefore, have to be made from among those who have successfully qualified for the position.

The former system, based on selection by appointment, was not perfect, but when compared with the present vicious practice, founded on the uncertain whims of temporary political fancy, it was as the sublimity of virtue contrasted with the evil of vice.

In seeking the change, the miners were led to believe that their interests and safety would be better guarded if inspectors were elected. It was asserted to them that the new scheme would eliminate corporation control of the men chosen, and that the proposed plan would open the way to quicker advancement for ambitious miners.

The plain truth is that the standard of mine inspection in the anthracite field has been lowered. What was intended to be a remedy has proved nothing less than a worse disease. The dignity of the office has been reduced and efficiency and independence largely destroyed.

Under the present plan, the inspector must cater to the wishes of political leaders. He is often made the instrument of retaliation, and at times is obliged to leave his post of duty, and precipitate himself into the midst of a political campaign, spending weeks in electioneering and thus neglecting the work for which the state pays him.

Furthermore, the perniciousness of such an election system doesn't end with inefficient colliery inspection; it extends to the actual operation of the mines, in that it has a direct bearing on the selection of mine foremen and firebosses. The inspector is a member of the examining board, and recent cases have occurred where candidates unqualified in training, but possessing political influence, have secured foreman and fireboss certificates when all facts argued their incompetency.

Interested parties backed by certain papers have recently suggested a still further step toward the complete demoralization of the anthracite inspection service. They advocate that all mine foremen be made eligible for election as inspectors, and recommend the abolition of the present system whereby only candidates who have successfully passed an examination, are permitted to go on the ballot.

In addition to all that has just been stated, the present method of choosing the inspectors is unfair. Instead of the voters in a certain district electing their own inspector, the people (including farmers and tradesmen) in another nearby district, vote for the candidate who aspires to serve at mines in which they have no interest or acquaintance.

Laws are of no avail unless they are enforced. If the public approves an inspection system that encourages laxity in the observance of vital legislation, then the people, or rather their representative, the state government, should assume responsibility in case of accidents.

Last year in New York City, there were 35,000 burglaries—how many more were not reported we hesitate to guess. This record of crime, which in comparison, makes Hell's Kitchen, Arizona, look like a Sunday meeting of the Y. M. C. A., was caused by corrupt politics. Each man from the top official down to the lowliest patrolman is so busy "getting his" he hasn't any time to do duty as a policeman.

In contrast, look at our fire departments. Here "big business" has stepped in and declared: "We can't have fires; millions in property are at stake." What is the result? Efficiency, courage and an "always on the job" spirit pervade the service. Politics hasn't been permitted to embrace the department in its deadly clasp, and the men are seldom changed. By years of service they become experts in execution and models in obedience. Start to a New York fire and ten to one you will meet the engines coming back.

Why is it we view the safety of life in our anthracite collieries with less concern than we do property values? And why do the men themselves, who are most vitally concerned, permit self-interested leaders to hoodwink them into advocating and supporting a system fraught with danger to mines and men? Let us have any system, where the candidates are examined and appointed by the governor in the order of merit, rather than the present practice, where an inspector is liable to be ousted just when he has become familiar with his properties, and is prepared to be of maximum service to all concerned.

What do our readers think about this question?

Mining Methods in Illinois

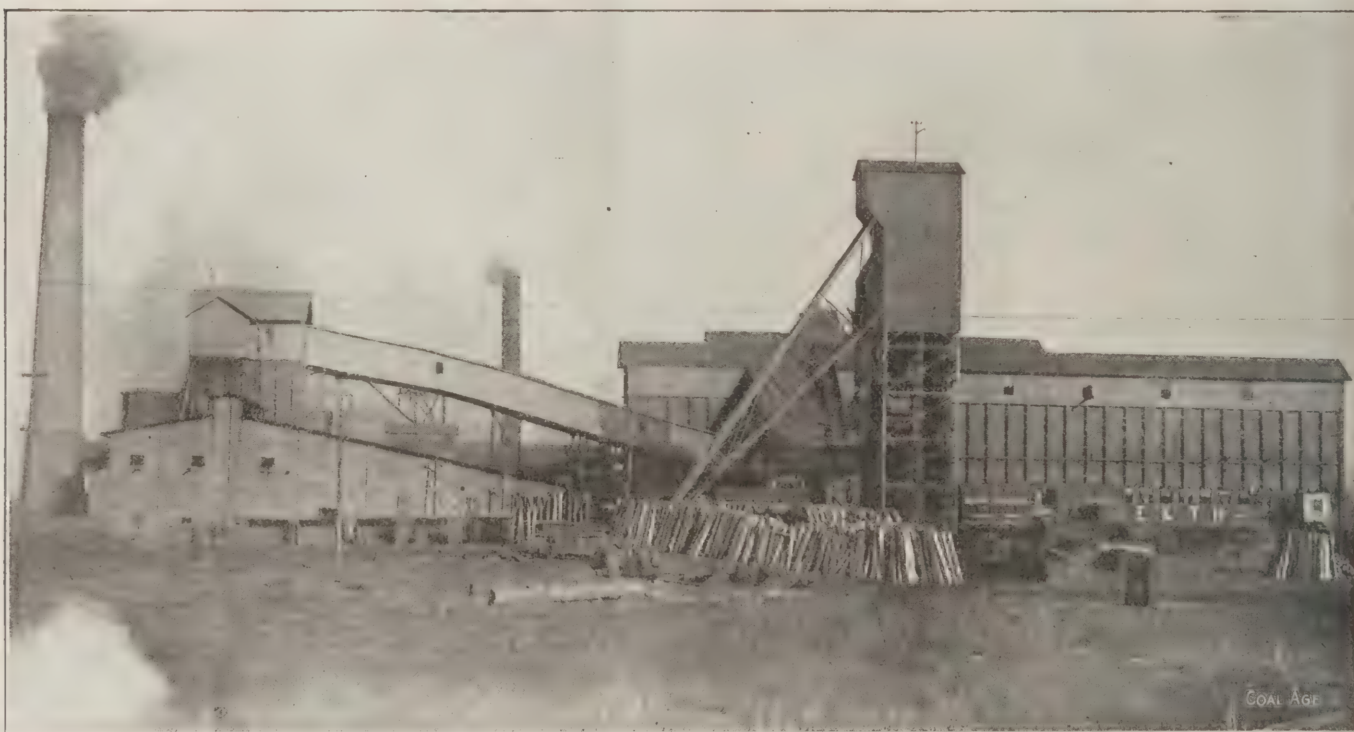
By M. F. Peltier*

A general description of one of the most important fields in Illinois. The equipment of the plants is modern in every respect and large tonnages are produced. The mines are mostly shaft openings, but comparatively shallow.

*Mining engineer, Peabody Coal Co., 2535 South Park Ave., Chicago, Ill.

The Williamson County coal field or, as it is better known, the Carterville Bed, underlies the whole north half of the county and is found at different depths up to 200 ft. This field belongs to the Eastern Interior Coal Field, and the seam is designated by the Geological Survey of Illinois as the No. 7 seam. The thickness is from 8 to 9 ft. throughout the developed portions of the seam.

The salient feature of the field is an elongated basin, toward which the strata dip from every direction. The highest portion of the basin is in the southern part of the county. The coal outcrops about 1½ miles north of the city of Marion. The central part of the field is disturbed by a sharp fold or fault, with a down-throw of several feet. This fault extends from the outcrop in a northerly direction, and crosses the property of the Chicago & Big Muddy Coal Co. near their main shaft. The displacement at this point is nearly 50 ft., which necessitates using an incline to handle the coal.



Surface Plant at the Peabody Coal Co.'s Mine No. 3, Marion, Ill.

Historical

The exact date of the discovery of coal in Williamson County is not known, but as early as 1850 coal was mined on the farm of Elijah Spiller, at Spillertown. The methods employed in mining, those days, were primitive. The coal having a light cover, they usually sunk a shaft about 8x10 ft., and mined out only a small portion within easy reach, abandoned the shaft, and sunk another.

This coal was used only for smithing purposes, wood being so abundant at that time that coal was not used for fuel. It was hauled by wagons to Franklin, Saline and Jefferson Counties for the leading blacksmiths, and was known as the Famous Peacock Smithing Coal, on account of its peculiar formation and beautiful coloring effects.

The first incorporated company and shipping mine was formed in 1872 at Carterville, and was known as the Carbondale Coal & Coke Co. This mine was operated as a slope and very primitive methods of mining were employed. The mining was all done by hand, powder or other explosives not being used; only screened coal was marketed, the slack and dust being left in the mine. The Herrin field was opened up in 1896, the Big Muddy Coal & Iron Co. being the first to operate a mine in this district.

The first railroad built in the county was known as the Carbondale & Shawneetown R.R., and extended from Carbondale to Marion, a distance of about 18 miles. This road was completed on Jan. 20, 1872, at Marion, and later was extended to Paducah, Ky. The road changed hands several times and was finally taken over by the Illinois Central R.R., the building of which caused considerable activity in coal mining in this region.

Production and Quality of the Coal

The Carterville bed is remarkable, not only for its variations in quality and thickness, but also because it is free from horsebacks, slips and other irregularities, encountered in other fields. This and the Franklin County field are considered the most important in the state. The coal shows a calorific value as high as 13,000 B.t.u. The following analysis of a sample from the Peabody Coal Co.'s Mine No. 3, at Marion, may be taken as typical of the field as a whole:

Moisture	5.70
Fixed carbon	55.31
Volatile combustible	32.00
Ash	5.91
Sulphur	1.08

Williamson County is the largest producing county in the state, and according to the Illinois Coal Report produced 5,908,544 tons of coal last year; this is considered a remarkable record, in view of the fact that the average number of working days during the year was only

161. This reduction in work at the mines was caused chiefly by the delay in the operators and miners reaching an agreement upon a wage scale because of which mining was suspended from Apr. 1 until Sept. 10, 1910.

There are 38 shipping mines in the county and 17 small local mines. Williamson County has advantages over other mining districts, in regard to transportation, having six large railroads traversing it, which not only insure a good supply of cars, but give the operators an unlimited market for their product.

System of Working

A general uniformity in mining methods prevails throughout the county, with the exception of slight modifications which are rendered necessary where the seam dips from 2 to 3 per cent.; then the main entries follow the dip and the side, or stub, entries are turned off at angles to secure easy haulage and drainage. The room-and-pillar system is universally used throughout the entire field. The mines are nearly all opened by shafts, although there are a few local mines opened by drifts where the position of the outcrop renders it possible.

The majority of the mines are laid off in panels. The main and stub entries are driven 12 ft. wide and 20-ft. pillars are left between entries. Rooms are turned off the stub entries at right angles on 34-ft. centers and driven 250 ft.; they are 20 ft. wide, have 14-ft. pillars, and crosscuts every 60 ft., as prescribed by the state mining law. The main and side entries are protected by a barrier pillar from 50 to 100 ft. in thickness.

Pillars are not drawn in this field, but when a room is completed a start is made from the face and a slab taken off along the rib, leaving only a thin pillar to support the roof. Complete robbing of the pillars has not been very successful, owing to the thin covering and weak roof; when there is a large space left open it generally caves to the surface, giving considerable trouble, due to surface water.

The roof throughout the different mines is considered only fair; the majority of the operators leave a portion of the top coal in the entries to support the roof and when this gives way immediate timbering is necessary to secure the slate above it. At the main landings, near the shaft bottoms, the roof is supported with steel I-beams on masonry walls, or heavy white-oak posts. The rooms are all timbered with a double row of posts spaced at least 6 ft. apart.

Water Problems and Mining Methods

Most all the mines have considerable water to contend with. Small pumps are used to collect the water from the workings near the coal face and deliver it to a large sump, which is generally located at some convenient place near the shaft bottom; from here the water is thrown to the surface by a single large pump. There are a great many different types of pumps used, the electric being one of the favorites for inside work.

The mining conditions in general are quite favorable for both picks and machines. In the pick mines, the coal in the rooms is all blasted from the solid with black powder. The entries are cut or sheared in the center by the miner, who uses a light short pick for that purpose. The cutting is made from 8 to 10 ft. long, and only sufficiently wide to admit the miner.

An Underground Scene at the Peabody Coal Co.'s No. 3 Mine

In the machine mines the undercutting is done in the bottom coal, both in rooms and entries. The electric chain breast machine seems to be preferred, although there are a great many punching machines used, which are operated by compressed air. Over 33 per cent. of the entire tonnage was cut by machines in Williamson County last year, notwithstanding the unfavorable machine mining rate, there being a differential of only 7c. per ton between machine and pick mining. The pick miner receives 54c. per ton of mine-run while the machine runner, helper and loader receive a total of 47c. per ton.

The holes for blasting are drilled with the usual hand drills; the depth of the holes depends entirely on the length of the cutting. The amount of powder used is measured by the number of inches in the length of the cartridge; a 2-in. cartridge, which is generally used, contains a little over one pound to the foot. The miners are not very particular in regard to the amount of powder they use, as they are paid on a mine-run basis, and the more powder they use in blasting and breaking up the coal, the less the labor of producing it.

Map of the Peabody Coal Co.'s No. 3 Mine, in Williamson County, Illinois

Mining Details

According to the Illinois Coal Report, there are 24 mines in which machines are not in use; 6 mines in which machines are used exclusively, and 9 in which both pick and machine mining are used. There was approximately 1,832,915 tons mined by machines and 3,714,443 by hand. After the Cherry mine disaster the state legislature passed a law, compelling all operators to install telephones in the different mines, for use in case of accidents or fires. The telephones are used, not only for communicating in cases of threatened danger, but also in the general operations of the mines.

There are two different kinds of haulage in common use in the mines, mule and electric. The mules are used for gathering the cars from the coal face and delivering them to a parting; the electric motors take the coal from the partings to the shaft bottom where it is hoisted to the top. Gathering motors, used instead of the mules, would be of material advantage, owing to the fact that most of the mines use a large mine car, some of which have a capacity of from 3½ to 4 tons.

In all of the large mines the track on the main haulage roads, where motors are used, is laid with 35- and 40-lb. steel on large white-oak ties. The side entries and rooms are laid with 16-lb., and the bottom partings at the shaft with 60-lb. steel.

There are two methods employed in caging the coal. In some mines the coal is caged on both sides of the shaft while in others all the caging is done on one side, the empties being taken off on opposite side. The method of caging on one side is more generally favored. The mines throughout Williamson County are well ventilated. The type of fan generally used is the blower, and is generally reversible. The mining laws of the state require that the quantity of air in circulation shall not be less than 100 cu.ft. per minute, for each person, and 600 cu.ft. per minute, for each animal in the mine.

Preparation of the Coal

A great deal of attention is paid to the preparation of the coal, every precaution being taken to see that the product is well cleaned and sized. The coal is all hoisted with self-dumping cages, dumped from the mine car into a weigh pan, and then passes over a double shaker screen. The top screen has 3-in. perforated-plates that allow the nut and slack to fall through on the bottom screen, which separates the nut

from the slack, or collects the two together as may be required. The portion of the coal that goes over the 3-in. perforated-plate, then passes over a section of 6-in. perforated-plate, making a 3-in. egg and a 6-in. lump. Four railroad cars are loaded at one time by this method.

Coal washing is carried on extensively throughout the field; at mines, where they have washing plants, all of the 3-in. or small coal is washed. The principal impurities in the coal are ash, in the form of slate, and sulphur in the form of pyrites. The large pieces of slate and sulphur can be removed from the egg and lump by hand picking. After the coal is thoroughly washed it is carefully separated into different sizes. Washed coal finds a ready market, as it has a greater calorific value.

Summary

The mining districts throughout the county are all pleasantly located, especially at Herrin and Marion. Marion is the county seat and is an enterprising city of nine thousand inhabitants. The miners are of superior intelligence, mostly Americans. The majority of them own their own property.

The shafts throughout this field have double hoisting compartments, and the tipples are built mostly of steel and equipped with all modern appliances to handle and screen the coal with the least amount of breakage. The engine houses are generally built of fireproof material and first-motion engines are mostly used. The boiler houses also are built of fireproof material and are usually equipped with tubular boilers.

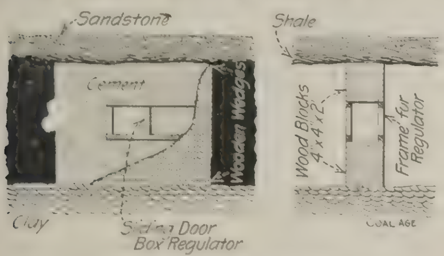
The same conditions exist in this district as in the whole competitive field, that is, the output far exceeds the market requirements. The competition is so keen and the selling price so close to the actual cost of production that there is often nothing left to take care of the depreciation of the plant and equipment, much less a fair interest on the investment. The chief beneficiaries of these conditions are the railroads, who generally name the price they will pay for coal.

Wood Block Stoppings

By Joseph Daniels*

Although gob, brick and concrete are widely used for mine stoppings, the use of timber blocks for this purpose is by no means common. In the mines of the Roslyn Fuel Co., at Roslyn, Wash., however, wooden blocks, 4 in. square and 2 ft. long, are in general use for building stoppings and dams.

The floor in the crosscut, or passage, in which the stopping is to be erected, is leveled off and the rib coal is cut away to a depth of 4 in., and for a distance of 2 ft. along the length of the passage, 2 ft. being the length of the blocks used. Also, the roof is straightened up as well



Wood-block Stopping

as possible. A course of blocks is laid on the floor and in each succeeding course the joints are broken or staggered. The 4-in. notch in the rib coal permits of a better bond than would otherwise be possible, and when the courses of wooden blocks are laid up to the full height of the opening, wooden wedges are driven in around the sides and top of the stopping to make the whole mass as compact and secure as possible. Later, both faces of the stopping are covered with a cement mortar, mixed from one part cement and two parts sand.

When the stopping is part of an overcast, the construction used is practically the same as described above, except that wooden stringers are placed on top of the stoppings to carry the bottom timbers of the overcast proper.

In some cases it is necessary to provide a door regulator in the stopping. With the wooden-block form of construction, this is easily accomplished by making two frames of the desired cross-section and placing these in position when building up the blocks. The necessary opening is thus left and the usual sliding door for regulating the amount of air is placed on the outside of the stopping, as is common practice.

The advantages claimed for this method of building a stopping are: 1. Low first cost; an ordinary workman can erect a stopping 6 ft. wide and 5 ft. high in eight hours, and the cost of materials, wood and cement facing, are exceedingly low. 2. The stopping is absolutely airtight and any squeeze or pressure coming on the wall compresses it and holds it together better than would be the case with other materials. For building dams, a similar method of construction is employed, the size of the blocks and their length being varied to suit the particular conditions existing at the mine.

*Department of Mining, University of Washington, Seattle, Wash.

Coal Famine at Butte, Mont.

Editorial Correspondence

Our worthy contemporary, *Fuel*, says in a recent issue:

> While there never was what might be truly termed a coal famine in Butte, Mont., there have been times in past winters when there was danger of one. Since the Roundup Coal Co. commenced to send its supply to Butte, however, all danger of a coal scarcity was eliminated. The late W. W. Taylor, general superintendent of the coal property of the Milwaukee R.R. Co., once said that all along the line of the road in this state there never would be a scarcity of coal, even if the road had to buy its own fuel. His statement has been borne out by facts and over the Milwaukee line, from the famous Bull Mountain field, has since come a continuous supply of coal which has increased in volume from month to month. The figures for all the months of the winter show large increases over last year. Even if less coal is consumed on the hill at the present time on account of the use of compressed air for hoisting purposes supplied by electricity, the diminished demand for coal has not affected the Roundup company.

With due respect to Mr. Taylor as a man who stood at the top of his profession in the West, other operators in Montana will probably take exception to the above statements.

In the fiscal year ended Oct. 31, 1911, Musselshell County, in which the Roundup mines are located, produced 643,648 tons. During this same period, Cascade County produced 948,823 tons while Carbon County showed a production of 1,226,783 tons, or nearly twice that of Musselshell County; in fact, the production of Musselshell County is only a trifle over one-fifth the total output of the state, and in addition to this, heavy tonnages of Wyoming coal are shipped into Montana.

Despite the reassuring words of *Fuel*, we do not believe that any particular congratulations are due the consumer in Butte because of the Roundup mines.

Anthracite Storage Possibilities

Apropos of the impending strike, facilities for accumulating surplus supplies are of interest. Eliminating the storage facilities in yards and on piers at seaboard or lake points (for which there are no figures), it is estimated that the storage capacities of the principal operating anthracite companies are as follows, in long tons:

Lehigh Valley R.R.	1,585,000
Reading	1,110,000
Pennsylvania (Susquehanna Coal Co.	880,000
Erie (Pennsylvania Coal Co.)	565,000
Central R.R. of New Jersey (Lehigh & Wilkesbarre Coal Co.)	560,000
Delaware & Hudson	270,000
Lehigh Coal & Navigation Co.	240,000
Lackawanna Coal Co.	200,000
Ontario & Western	180,000
Total	5,590,000

Coal Mining Institute of America

A meeting of the board of directors was held in the office of S. A. Taylor, Pittsburg, Mar. 9. Seven members of the board were present. It was decided to hold the summer meeting of the institute in Johnstown, Penn., June 19 and 20, and to confine the sessions to a discussion of practical problems.

Electrical Machinery for Coal Mines

By Sydney F. Walker*

The shunt-wound continuous-current motor and the three-phase induction motor are the types best adapted for general use in colliery work. The similarity of the two forms, their advantages and disadvantages, are here discussed with special reference to their constant speed and self-governing properties.

*Bloomfield Crescent, Bath, England.

For practical purposes, the shunt-wound continuous-current motor and the three-phase induction motor, are best adapted for use in colliery work. Series-wound, and compound-wound continuous-current machines are, of course, readily obtainable, but except in special cases, the shunt-wound continuous-current type is the one most suitable for almost every kind of colliery work that can be named.

Comparison of the Two Types

The shunt-wound continuous-current motor and the three-phase induction motor have gradually forced their way into general use, not only in coal mining, but in a great many other industries. There is a striking similarity in their behavior, particularly in the matter of government. The shunt-wound continuous-current motor, and the three-phase induction motor are the most perfect self-governing machines for the delivery of power, that have been devised up to the present.

It will be remembered that when driving machinery with steam engines, even those having the latest modern governors, a certain sensible time is required to admit the additional steam demanded with an increased load, or to shut off the steam that is not required with a decreased load. Further, it will also be remembered, that while steam engines are now made to maintain a uniform speed within about 2 per cent. of the normal, government for an increase or decrease of load is always preceded by a slight slowing up or increase of the speed of the engine, the speed returning to its normal value only after the new conditions of steam requirements are accomplished. The same remarks apply to engines driven by compressed air. And the reason for this is that there are three or four sets of apparatus which have to take part in the operation.

In the case of a steam engine, for instance, if the load increases, the engine slows slightly; the governor balls fall inward slightly, and either the throttle valve is opened a little more, or the slide valve or its equivalent, is caused to remain open for a little longer portion of the stroke. In any case, the operations one after the other take a certain sensible time, and while they are going on, the driven apparatus has its speed varied

With the shunt-wound motor, and the three-phase induction motor, the operation is practically instantaneous, and is perfectly automatic. In the case of both machines, with an increased load, the rotating portion slightly decreases its speed and this decrease of speed allows the necessary increase of current to pass through the coils of the machine to furnish the increased power required. With a decrease of load, the rotating portion slightly increases its speed, thereby automatically cutting off the excess current that is now no longer required. In both cases there is a difference in the speed at which the motor runs with different loads, but the difference throughout a wide range of variation of load, is trifling.

In the case of the three-phase induction motor for instance, what is called the slip is never more than 4 per cent., except when an excessively abnormal load is being driven. As explained in a previous article, the motor will go on slowing up, and will deal with largely increased loads at lower speeds, but for ordinary work, such as would be dealt with by a well governed steam engine, the variation of speed between no load and full normal load, is trifling. For all practical purposes the speed is constant. In the case of both classes of motor, it can be made absolutely constant, if the machine itself is made large enough.

How the Government Is Accomplished

As mentioned above, the governing is perfectly automatic; it depends upon the application of the same principles in the two machines, but in a slightly different manner. The government of the shunt-wound continuous-current motor depends upon the fact that the armature of the motor, when revolving, creates a reverse pressure, tending to reduce the current passing through the motor coils. When the motor is at rest, the whole pressure of the service, if allowed to do so, would drive a large and destructive current through the motor coils. To prevent that, the well known starting switches and resistances are employed, which reduce the pressure applied to the motor on starting, and until it has come up to its normal speed. The conductors upon the armature of the shunt-wound motor, being in motion in the magnetic field in which the armature as a whole revolves, obey one of the laws of magneto-electric induction, and create an electrical pressure in their own coils, directly opposing that of the current which is causing them to rotate.

The working current with a continuous-current motor is the difference between the service pressure, and the reverse pressure created by the armature coils when running. This difference of pressure is usually a very small percentage of the service pressure. The energy taken by the motor, and converted to mechanical power, is measured by the electrical pressure delivered to the terminals of the motor, multiplied by the current passing through the motor coils; but the current passing through the motor coils is due to only a small pressure, usually a few volts. The electrical resistance of the armature coils of a continuous-current motor is small, and therefore a small pressure is sufficient to drive the necessary current through them. Hence it follows that a very small increase or decrease of the pressure causing the current to flow through the armature coils, is sufficient to cause a comparatively large increase or decrease of that current. Hence the automatic and perfect government.

The Government of the Three Phase Induction Motor

In the case of the three-phase induction motor, the currents passing in the rotor coils are due to the difference in the speed of rotation between the rotor itself, and the revolving magnetic field. This difference is called the slip. If it were possible to eliminate all the load upon the rotor, it would revolve at the same rate as the magnetic field, and the current created in the coils of the rotor would be nil. With a light load, the rotor increases its speed, and thus decreases the slip, and with it the current created in its own coils. With an increased load, the rotor increases its slip, and with it the current created in its own coils.

Again the electrical energy delivered to the three-phase induction motor is measured by the pressure at the terminals and the currents passing. To find the actual amount of energy, the power factor, and another factor required by the three-phase system, have to be taken into account, but they need not be mentioned here. The currents passing in the rotor coils are "induced" in them by the variations in the currents passing in the stator coils. The action is exactly like that in the stationary transformer, with the difference that in the case of the three-phase induction motor the secondary coils are in motion, whereas in the ordinary static transformer they are fixed. The same series of operations, however, goes on.

The quantity of current passing in the stator coils is determined by the load upon the rotor, and this again determines the amount of slip between the rotor and the revolving field. While the variations of the currents passing in the stator coils induce the currents in the rotor coils, the latter also react upon the currents in the stator coils. When the slip is small, that is to say, when the load is light, the inductive effect of the rotor coils upon the stator coils tends to decrease the current passing in the stator coils, by causing an increase in the reverse pressures, much as with the continuous-current motor. When the load is increased, and the slip is increased, the inductive effect of the rotor coils upon the stator coils is lessened, with the result that more current flows through the latter, the effect being the perfect self-government that has been mentioned.

Another Point of Similarity.

Another important similarity between shunt-wound continuous-current motors and three-phase induction motors, but one which so far has not had any appreciable effect in colliery working, so far as I am aware, is the fact, that both machines are reversible in the sense of working as either a motor or a generator. When furnished with an electric current, they will deliver mechanical power; and, on the other hand, if driven by mechanical power, they will furnish electric currents.

The shunt-wound continuous-current machine is made originally to be used either as a motor or a generator. Its reversibility comes into play in a case where it may be driving some machine as a motor, and under certain conditions, the machine takes charge of it. The electric tram car illustrates this point. If shunt-wound continuous-current motors are employed in driving tram cars, they furnish mechanical power, under all conditions, except when going down hill. When descending a steep gradient, it should be possible to use them as efficient brakes. The power delivered to them by the descending car, should pump current back into the trolley line. It has been found somewhat difficult, however, to arrange for this in practice.

The three-phase induction motor will behave in exactly the same way, although I believe there have been no cases where this property has been made use of. It might be, however. It should be mentioned that all motors and generators are interchangeable; that is to say, they will all work as motors or generators, but the conditions of working, the conditions under which they will produce motive power or current, are usually different from those ruling with shunt-wound continuous-current, and three-phase induction motors. The great advantage about these two forms of motor is the practically constant speed. As mentioned above, it is not actually constant. It varies with the load, but only slightly; and when reversal of operation takes place, when a machine that has been running as a motor, furnishes current as a dynamo, its speed should be approximately the same.

Speed Regulation of the Two Types

This is the point at which the two forms of apparatus part company. The speed of the shunt-wound continuous-current motor can be regulated within wide limits. The shunt-wound motor, as ordinarily constructed, can be made to vary its speed 25 per cent. on either side of the normal, if required, by varying the current passing through its field-magnet coils. Weakening the current passing through the field, allows the motor to run faster; and if more current is at the same time allowed to pass through the armature coils, more work will be done, and *vice versa*.

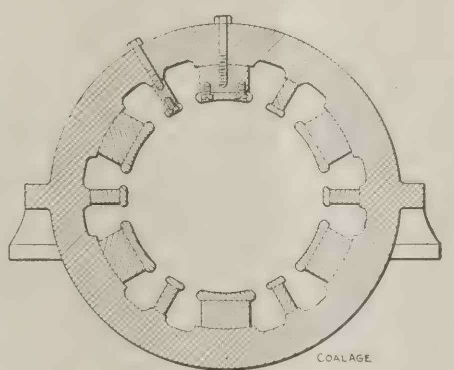


Fig. 1. Field of Interpole Type of Motor

There is a limit, however, to varying the speed of the shunt-wound motor, owing to the increase of sparking at the brushes. The brushes are mounted upon a rocking arrangement, which allows them to be adjusted to meet the difference in the strengths of the magnetic fields produced by the field magnets, and the armature. It may be mentioned that it is the struggle, as it were, between the magnetic fields created by the two parts of the machine, which leads to a certain amount of the sparking. When the magnetic field of the electro magnets is decidedly predominant, sparking is reduced to a minimum. It increases with everything which lessens the difference between the strengths of the two fields. Hence, when the current in the field-magnet coils is reduced, and that in the armature coils is increased, the tendency to sparking also increases.

The sparking is reduced by moving the brushes through a certain arc, but a limit is found when reduction of sparking is no longer possible. For shunt-wound motors which require to have their speeds regulated between wide limits, special provision is made by the addition of what are called commutating poles, or interpolar field magnets. Small electro magnets are fixed on the inside of the containing cylinder, , pointing radially inwards, similar to, but smaller than the field magnets proper. The office of these is to neutralize the excessive sparking, by practically suppressing the current which passes in each coil as it moves under the brush. With commutating poles, the speed of shunt-wound continuous-current motors may be varied in the ratio of 1 to 6; that is to say, a machine running at 400 r.p.m. may be run at from 100 up to 600. Fig. 1 is a cross-sectional view of the containing cylinder and field magnets of an interpolar machine.

It should be understood that the shunt-wound continuous-current motor has two properties. When furnished with its normal field-magnet current, it will run at an approximately uniform speed, varying only slightly with large changes of load. It can also be arranged to have its speed varied within the wide limits mentioned above, and the two properties can be combined in the same machine.

It also has another property. It will go on furnishing power when demanded, by steadily slowly up, and allowing more and more current to pass through its armature coils, until the heating effect of the current is so great that the insulation is destroyed.

Speed Variation of the Three-Phase Induction Motor

With the three-phase induction motor, the means of varying the speed are but meager. Certain fractions of the normal speed may be obtained by cutting out a portion of the magnetic fields. It was mentioned above that there are several sets of coils in the slots of the drum forming the stator. Each set of coils and the set on the opposite side of the drum, represent a group of magnetic fields and a pair of magnetic poles. By cutting down the number of pairs of poles by half, the speed at which the motor runs is reduced in the same proportion. Similarly by cutting it down 25 per cent., the speed is reduced by 25 per cent.

The speed at which the motor runs depends upon the number of pairs of poles in the stator, and the periodicity of the currents. The usual periodicity with modern alternating-current machines is 50 periods per second, or 3000 per minute. For a machine to run at 500 r.p.m., therefore, there will be six pairs of magnetic poles, twelve sets of currents. By cutting out two sets of poles, the speed would be reduced by 33 1/3 per cent and so on.

News of the Coal Strike Situation

Special Correspondence

The demands of the anthracite miners have met with a blunt refusal; and modifications must be discussed or a strike called. The bituminous fields await the result of the joint conference in Cleveland, Mar. 20. Progress of strikes in Great Britain, Germany and France.

Over 1,000,000 miners have been on strike in Great Britain since Feb. 29; about 200,000 men are now striking in the Westphalian coal fields of Germany; two-thirds of all the French coal-mine workers recently indulged in a 24-hour exhibition strike to proclaim their unity in support of certain demands; 45,000 miners in Belgium now threaten to strike; and in the United States "coal strike" is being talked of from one end of the country to the other.

There is little doubt that the strike of British miners has exerted at least a moral influence in bringing about the minor demonstrations in Germany and France. It may be expected that it will also, to some extent, have a similar influence in the United States.

The demands of the anthracite miners in this country have met with an unqualified refusal from the operators, as was more or less expected by everyone concerned. The operators make it known, however, that they will consider any modified demands that the miners may arrange to present.

No definite conclusions regarding the outcome of the controversy in the bituminous field can well be drawn until after the joint conference, in Cleveland, on Mar. 20. Even if a basis of agreement is reached at this meeting, there will scarcely be time enough before Apr. 1 to arrange the various state contracts, but, it is just possible that in such an event, there will be no general suspension of work on the expiration of the present agreements.

The Illinois miners have, however, voted to go out pending the adjustment of a wage scale, and the Iowa and Indiana organizations are confidently expected to follow suit. Similar action has also been customary throughout Pennsylvania and Ohio. The mine workers of Missouri, Kansas, Texas and Oklahoma are bound by agreement to remain at work for at least 30 days after Mar. 31, pending a negotiation of the new contract.

Anthracite Conference

At the conference of anthracite operators, held in New York City, Mar. 5, a large number of independent coal men were represented, as well as officials of all the larger mining companies. The conduct of the meeting was reported to have borne some evidence of prearrangement. It was agreed to refuse the demands of the miners *in toto*; and a committee of ten was appointed to present this reply to the miners' representatives at the joint conference in New York on Mar. 13.

The opinion of the conference was unanimously expressed as against a one-year agreement, and although a five-year term was advocated by some, the majority favored a three-year contract. The demand for an eight-hour day was opposed on the ground that, to reduce the hours, means an increase in wages and a reduction of output. Recognition of the union and the "check-off" was refused partly because these provisions would virtually amount to making the operators act as agents to help support the Union. The abolition of the conciliation board was opposed on the ground that this board has proved itself an efficient means of maintaining stable conditions in the industry.

The demand for an increase of 20 per cent. in wages was declared by the operators to be exorbitant. However, the advisability of offering a 5 per cent. increase has received serious consideration from the heads of some of the large coal companies.

Bituminous Conference

Representatives of bituminous-coal operators and miners met in Chicago, Mar. 5, and agreed to hold the second joint-scale conference in Cleveland, Mar. 20. W. K. Field, of Pennsylvania; E. A. Cole, of Ohio; J. C. Kolsen, of Indiana, and H. N. Taylor, of Illinois, represented the operators. John H. Walker, of Illinois; Francis Feehan, of Pennsylvania; John C. Moore, Ohio, and W. D. Van Horn, Indiana, together with John T. White, president of the United Mine Workers, represented the miners.

The demands of the bituminous miners are briefly as follows: (1) Payment on the mine-run basis; (2) flat increase of 10c. per ton; (3) seven-hour work day, five hours on Saturday; (4) 20 per cent. increase for all day labor; (5) weekly pay days; (6) no limit to the deductions made by employers for miners' organizations; (7) readjustment of the machine differential at the basing points in the competitive states.

Illinois Convention

The convention of Illinois miners adjourned, Mar. 1, after adopting a scale of wages prepared by its scale committee, and after voting to quit work, Mar. 31, pending the conclusion of an agreement with the operators. The schedule of wages adopted would have the effect of adding about 2c. a ton to the present cost of mining even before the percentage increase is added that is called for by the demands of the national convention.

After a short session, Mar. 1, the conference between representatives of the miners in Missouri, Kansas, Texas and Oklahoma, and representatives of the Interstate Southwestern Coal Operators Association adjourned, subject to recall at any time. No steps of any consequence were taken in regard to deciding on an agreement, but it is expected that another meeting will be held in Kansas City as soon as some definite action has been taken in the central competitive field.

In strong contrast with reports from other fields is the news from Colorado that the strike of two years' duration in the northern field has been settled so far as the eight mines of the American Fuel Co. are concerned and several hundred men at Lafayette and Louisville have returned to work.

The British Strike

The British Government has been trying to bring the coal miners and owners together, and has at last succeeded, although the acceptance of the miners' delegates was coupled with the reservation that the principle of a minimum wage should be excluded from discussion. This, however, does not imply that the schedule of rates drawn up by the miners will not be discussed. The miners' representatives are not authorized to agree to any reduction of the federation's schedule of wages or to any scheme for determining these rates, without a new ballot by the miners.

Strike in Germany

A coal strike went into effect in the Westphalian coal fields, of Germany, Mar. 11, when more than 50 per cent. of the 350,000 miners, there employed, obeyed the call of their leaders to cease work. In some districts the cessation of work was practically complete, while in others only from 15 to 30 per cent. of the men went out. Several riots and numerous attacks on the men who continue at work and on the police are reported.

There is every probability of a coal strike throughout Belgium that will affect 45,000 colliers. The miners in the Liége basin have charged their delegates to ask for higher wages, and those in the vicinity of Charleroi have unamimously decided to ask for a 15 per cent. increase. If their demands are not granted they all threaten to go on strike.

A Successful Type of Rotary Dump

By A. E. Lindrooth*

The large number of disastrous mine explosions that have been caused by dust during the last few years has awakened the attention of mine operators to the need of controlling this source of disaster, particularly as regards accumulation of dust along the main haulage ways; and naturally, one of the most efficient ways to control dust is to prevent its formation. On haulage roads, a great part of the dust is caused by leakage of coal through the car doors, this coal being ground in the course of time into explosive powder.

The rotary dump shown in Figs. 1 and 2 was designed by the Link-Belt Co. for the Consolidated Fuel Co. of Hiawatha, Utah. It has now been in successful operation for the past 18 months and has entirely solved the question of leaky cars at this mine.

No motive power is required for operating this device. The pit cars are run onto the dump platform, which is equipped with locking horns and angle bars to keep the cars from falling off when overturned; and being pivoted on a shaft that is set somewhat off center, as soon as the foot brake is released the dump revolves and empties the car. After dumping, the counterweight causes rotation in a reverse direction and brings the empty car to an upright position, after which it is bumped off by the next following loaded car just as in the working of the ordinary cross-over dump. The operation is rapid, and is always under control of foot brake.

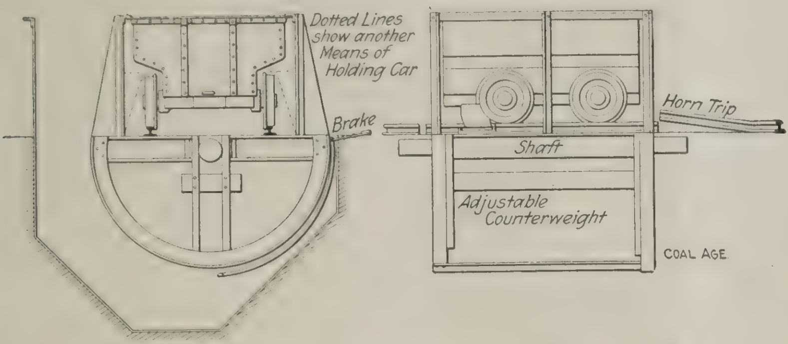

Fig. 1 Rotary Dump for Mine Cars

Fig. 2. Two Views of Rotary Dump, Showing Car in Normal and Dumping Positions

The advantage of this style of dump over the old-style end-tip dump is twofold. First, the elimination of the end door makes possible a perfectly tight car and thus entirely stops the leakage of coal along the haulage roads, a feature which is of obvious value in preventing waste and danger of explosions. The second point of advantage is the increased strength of the car. Without question, the weak points of the average mine car are the door and the door latch. Eliminating these two points, the car is made much stronger and entirely freed from the annoyance due to loose doors and broken latches.

This style of car dump has been in use for some time at other mines also and it is reported that the breakage of coal is no greater than with the ordinary end-tip form of dump.

*Boston Building, Denver, Colo.

Effect of Panama Canal on Shipping

When the Panama Canal is opened in the month of June, 1913, steamers *en route* from Europe to San Francisco will no longer go via Cape Horn, a route of 13,621 sea miles; but will save 6200 sea miles via the canal route. Steamers proceeding from Montreal to Sydney now cover 13,690 sea miles; but in the future will be able to do so over a route of 10,952 sea miles.

It is difficult to predict the effect of the canal upon freight traffic between Europe and Valparaiso, the Cape Horn route being only 2100 miles longer than the canal route. Passenger ships probably will pass through the canal, while the East coast of South America will be served by auxiliary ships sailing from West Indian ports. It is assumed that a part of the business from New Zealand to Europe, which today comes via Cape Horn, will pass through the canal hereafter, saving 1600 sea miles. The chief part of the steadily increasing business between New York and New Zealand should, therefore, proceed via the canal, rather than by the Cape of Good Hope, thus saving 2300 sea miles.

The probable changes in navigation routes will create equally great changes in the distribution of the coal trade, for which British firms are already making preparation. It is stated that British firms are now making arrangements to open a coaling station at Nukulopa, the capital of the Friendly Islands, and upon Pitcairn Island.

West Virginia Coal Mining Institute

The next semiannual meeting of the institute will be held during the second or third week of June in Charleston, W. Va.

The Japanese Coal Industry

By H. F. Bain*

The equipment of the Japanese mines is modern throughout. Larger volumes of water are handled as a rule than at any other collieries. Excellent sociological regulations are in force.

The Miike colliery, visited by one section of the American Institute of Mining Engineers, belongs to the Mitsui family, which, because of its wealth and age, has been not inaptly characterized as the "Vanderbilt family of Japan." The Mining Department of the Mitsui Gomei Kaisha (Mitsui firm) operates both metal and coal mines; and it was to the most famous among the latter that the visitors were taken.

Historical

The Miike colliery is situated on the Gulf of Ariake in the island of Kyushu. Coal has been known to occur at this point for many years, and was mined a little by native methods, even before the government in 1873 took possession, and under an English engineer opened the first modern pit. In 1889 the property was transferred to the Mitsuis, who made radical and extensive changes, opening new pits in succession, until there are now six working mines, with an average daily output of 6,000 tons. In 1910 the total output of the Miike mines was 1,799,489 metric tons, of which 41% was exported.

The Miike coal has a well established and enviable reputation throughout the Far East, for both its steaming- and its coking-quality. There are eight beds on the concession; but mining is, as yet, confined to the Miike or upper seam. This averages something over 9.5 ft. in thickness, has no clay bands, a hard sandstone roof and a firm fire-clay floor. The coal has been mined for a distance of nearly two miles along the strike, and is open nearly as far down the dip, which is 10 per cent. The deepest shaft, the Manda, which is 41x12 ft. in cross-section, is 900 ft. deep. From the bottom the workings extend down the dip to a total deph of 1132 ft. below sea level.

Large Volumes of Water

As the overlying material is a soft Tertiary sandstone, the amount of water to be handled is unusually large. Only in the Pennsylvania anthracite district are there any American collieries where the ratio of water to coal is comparable, and even there it is less.

At the Miike mines, 12 tons of water must be raised for each ton of coal won. At the Manda shaft alone, the ratio is 20 to 1, and roughly 1000 cu.ft. per minute were being pumped on the day we visited the pit.

To raise such a quantity of water from such a depth requires large and expensive pumps, and those at the Manda shaft are said to be the largest at any colliery in the world. The most impressive are the 4 Davey Cornish pumps, with compound steam-cylinders, of which the high-pressure is 45 in. in diameter, the low-pressure 90, the water-ram 22 and the stroke 12 ft. The pump has a speed of 8 to 10 strokes per minute, and two of the pumps are held in reserve. In addition, there are 5 Janesvilles, each capable of handling 300 cu.ft. per minute against a head of 900 ft., and various smaller pumping engines.

*667 Howard St., San Francisco, Calif.
Note—Abstract of paper in the January number of the Bimonthly Bulletin of the A. I. M. E.

Map of Japan, Showing Railroads and Mines

The final capacity of the pumps at this shaft is to be 3000 cu.ft. per minute against a 1000-ft. head. An aggregate of over 16,000-hp. is used in pumping, but, despite this, less than 10% of the coal mined is used at the colliery. Coal is also burned to generate steam for many purposes. The amount will be reduced when improvements now under way are completed. At present coke is made in beehive ovens, of which 60 are in operation, burning 300 tons of coal per day and making 180 tons of 48-hour coke. About one-half of the gas is now used. There are now building, however, Coppee ovens; and with the gas from these two, 2000-kw. gas-engines, will be driven to supplement the five 1000-kw. Curtis steam-turbine generator-sets now in the central power station.

Mining Methods and Sociological Conditions

The coal is worked on a retreating pillar-and-room system; the roadways being 20 ft. wide and spaced at 130 ft. intervals. The coal has an extremely irregular cleavage, and is mined without either powder or shearing. The miners (called "hewers" as in England) pick the coal from the face with small single-pointed picks, and are paid by the ton, as in America. The coal is forked into cars holding 1400 lb. and taken to the shaft by means of horses and endless rope. The close cleavage and the system of mining give a large percentage of fine coal, there being 45% of lump over a 2-in. screen, 10% of nut, between 2-in. and 7/8-in., and 45% under 7/8-in. The lump coal is sent over a picking belt, where women take out the slate. Nut coal is washed, and the fine coal is made into coke.

There are 11,700 mine workers, of whom 33% are women. The miners work in 8-hour shifts, but surface workers put in 10 hours. Nominally, wages are low, miners getting 35 to 40c. per day and women coal-pickers about half as much. This, however, does not tell the whole tale. For example, house rent is free in some cases, and nearly so in others. Food sold at cost or below. For rice, the staple food, the price is fixed; varying only with the term of service of the employee. Miners who have been with the company for five years are now buying their rice at about one-third what is costs the company in the open market.

There is a charge of 7½c. per month for sanitary service; but the boiled drinking-water is furnished to all miners' houses. Schools, hospitals, a day-nursey for children, sick-benefits, accident and

death-benefits, and amusements are all provided by the company; and, to serve miscellaneous wants, a store is maintained, with prices so regulated that in three years the total profit was less than $8. This is not the American way of doing things, but quite accords with the Japanese notion of regarding a business as a family enterprise and the employees as members of the family.

Excellent Management

The yield of coal per miner is about 2 tons per day, or 1 ton per employee. A larger supervising staff is employed than in the United States, there being 40 bosses for 2200 men. All the work about the shaft and indeed the whole property, has been excellently designed and executed.

A particularly commendable feature is the permanent character of the steel tipples, brick stations and stables, heavy rails underground, set on large ties and with rock ballast. When it is remembered that a modern colliery lasts 40 to 50 years and often longer, the real economy of such features, coupled with retreating mining, is apparent. That in a country of high interest charges such as Japan, the directors should go to expense in this direction, is especially striking.

The technical work at the mine is under the direction of a skilled force of engineers, graduates of the Imperial University of Tokyo. Among those at the mine may be mentioned Messrs. H. Uyeki, Vice-manager of mines; J. Fujioka, Mining Engineer; T. Tomita, Superintendent at the Manda shaft; T. Takasu, Superintendent of Transportation; D. Kurita, Superintendent of the Harbor; and K. Akabane, Manager of the Sales department.

The Practical Side of the Engineer

By H. G. Haffner*

Some notes and observations on the relations of the engineer to the underground officials. Maximum efficiency in mining is attained only by those in each department having a thorough understanding of the work done by the other branch of the industry.

The mining engineer should have two main objects in all his dealings with inside foremen and other inside employees:

First, their safety from any accumulated bodies of water, or gas, in any old workings of their own, or adjoining collieries.

Second, that the mining and robbing be done in such a manner that the greatest possible percentage of coal is removed at the least possible expense.

In order to see that the first object is carried out, the engineer should give the foreman safe distances to drive, when approaching old or abandoned workings containing accumulations of water or gas; also give courses, distances and dips at which to drill holes to tap these bodies of gas or water.

He should also give lines for driving all places along barrier pillars between his own and adjoining collieries for the present, as well as the future safety, of the inside employees.

His Responsibility

At many collieries, now working in this field, and operated years ago by individual owners, there are a large number of crop falls made in the Mammoth and Buck Mountain veins, which are now filled with water. The engineer should see that the inside foreman's attention is called to any workings approaching these crop falls, and have the water removed from them either by pumping it out or filling in; where practical, they can be filled with silt.

The engineer further aids the foreman by furnishing him with blueprints, to the scale of 100 ft. to 1 in., of all workings, or, better still, tracings which are posted every three months. Tracings are better for the foreman, as by having them he can, by fitting one over the other, see how the workings in one seam are in relation to the others. The prints, however, have the advantage that they can be taken into the mine and examined on the job. Personally I feel that the foreman should have both.

*Mining engineer, with Lehigh Valley Coal Co., Wilkes-Barre, Penn.

Note—Abstract of paper read before the Shamokin Y. M. C. A. Mining Institute, Mt. Carmel, Penn.

In flat or pitching seams, the engineer should place lines for driving all breasts. Where two or more splits of any seam overlie each other, with small partings of rock or slate between, breasts should be driven over breasts, and pillar over pillar, in order that the overlying strata be better supported, and the robbing of pillars carried on to the best advantage. Where the foreman wishes to drive counter gangways, for the purpose of reclaiming pillars lost in previous mining, the engineer can aid him by giving the proper elevation at which to start.

The engineer can also aid the foreman by seeing that the robbing is carried on systematically; that is, that the overlying seams are robbed in advance of the underlying.

He can also establish chain pillars for the support of the upper gangways, protection of tunnels, shafts and surface improvements, such as boiler houses, breakers, engine houses, etc. Where silting is to be done, he can lay out plans for the method of conducting the material to the different areas to be silted. After silting is completed, it should be carefully marked on the maps and tracings, in order that the foremen can readily see which areas have been silted in relation to the removal of the pillars.

The engineer should also keep the foreman advised as to where surface falls, from mining or robbing, are likely to occur adjacent to any bodies of water, culm, railroads or other surface improvements; where mining is done under towns this is a serious and difficult matter. It seems as though practically all the towns in this section of the anthracite coal fields were built over the coal basins, thus entailing an enormous additional mining expense to the coal companies, as well as the loss of considerable crop coal left in for the support of surface improvements.

Assisting the Foreman

In estimating the cost of new improvements, the engineer can aid the foreman materially, as these estimates are generally prepared by him and he is familiar with the cost of doing this class of work. This includes work such as tunnels, pumps, engines, column and steam lines, steel timber, etc., and quite often a scheme which looks good is found impracticable on making a careful estimate of the cost.

Steel timber is being largely used in permanent places, such as slope bottoms, turnouts in the main haulageroads, pump and engine houses, etc., in order to save the maintenance cost and decrease the fire risk. The foreman, wishing to place steel timber in any given location, will state the size of good timber, which he would suggest using, and refer the requisition to the engineer for figures on the correct size of steel timber.

When the foreman wishes to drive a breast through to the surface, for the purpose of ventilation or for any other reason, he calls on the engineer to place points on the surface so that the work can be done from both ends, thus saving considerable time.

The engineer on his trips to the mines often sees points which, in his opinion, could be improved, and he should offer suggestions to the foreman in regard to them. This should be done, however, not in a spirit of criticism, but only with the thought in his mind that they are both doing what is to the best interests of their employer.

Electrical Equipment, D.L. & W. Mines

Special Correspondence

The electrification of the D. L. & W. coal properties is unusually complete and extensive. Motors are installed, having a total rated capacity of 27,618 hp. The central-station and substation practice and the distributing system are here outlined as are also the applications of electric power to haulage, hoists, pumps, and other auxiliaries. The equipment of the Truesdale colliery is taken up in detail.

The electrical equipment of the collieries of the Delaware, Lackawanna & Western R.R. Co. is unusually extensive and the central-station and distribution systems are excellent examples of modern engineering. About 20 collieries are comprised in the operations of this company, all of them situated in Lackawanna and Luzerne Counties, in the northern, or Wyoming, anthracite coal field of Pennsylvania, their output for the year 1910 being approximately 8,000,000 tons. All these collieries, with two exceptions, use electricity for both light and power, and even these two have small isolated generating plants for lighting service only.

Most of the mines have had electric service for a number of years, the original equipment consisting of direct-current engine-driven generators, some of which are still in operation, while others are now held merely as reserves. The main sources of electric supply, at present, are two central stations, equipped with steam turbine-driven generators; one of these serves the upper district in the vicinity of Scranton, and the second supplies the lower district around Nanticoke.

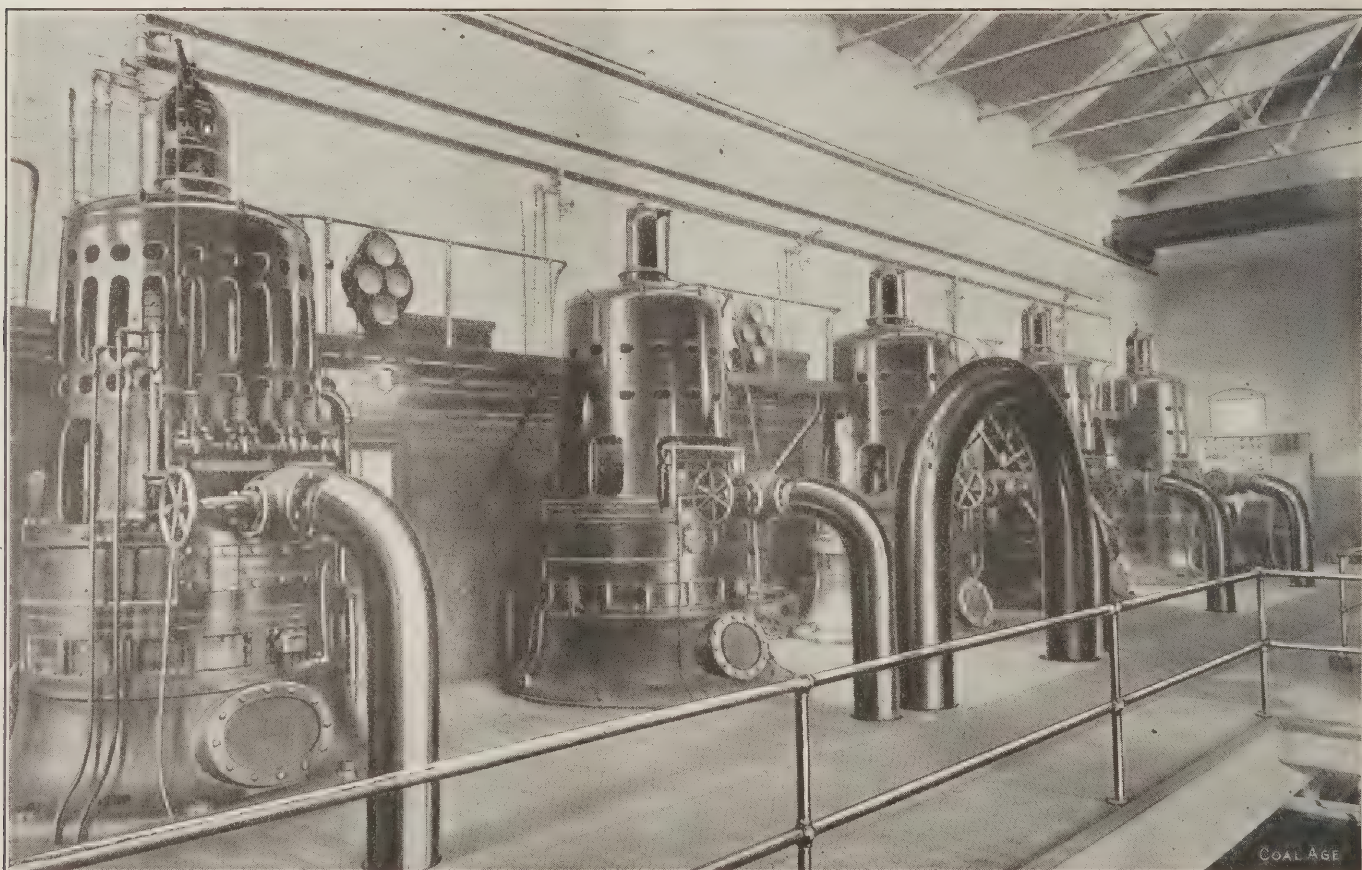
At the Hampton station, in Scranton, current is generated at 2300 volts, three-phase, 60 cycles, while the Nanticoke alternators are 4150-volt units. Three potentials are used in transmission. They are: 2300, 4150 and 16,000 volts. The capacity of the Hampton station is 6500 kw., that of the Nanticoke power plant is 2500 kw., and, in addition to these, there are engine-driven sets having a rated output of 2390 kw., so that the aggregate available generator capacity is 11,390 kilowatts.

Twenty-one rotary-converter substations are located at the various collieries, while a few of the more distant mines are not supplied with converters, but continue to operate the old engine-driven generator sets. The total number of rotary converters at present installed is 26, and their rated capacity is 6650 kilowatts.

Mine Haulage

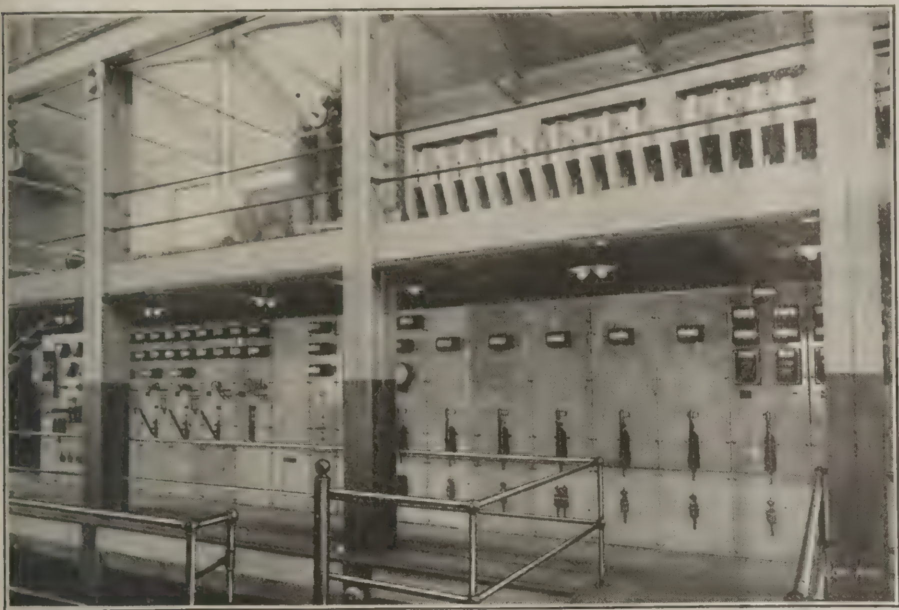
Electric mine locomotives are extensively used by the Lackawanna company, there being 170 now in service; 125 of these are 6½-ton cable-reel motors, and 45 are 10-ton straight-haulage units, making a total motor capacity of 10,750 hp. A large number of these locomotives operate at 250 volts, and current is normally supplied at 275 volts in order to take care of the line drop involved by the length of the feeders. In one mine 550-volt current is used for this service, and in five of the mines, direct current for haulage is supplied through a three-wire system at 275 and 550 volts. Also, five collieries have direct-current engine-driven sets arranged to operate in parallel with the rotary converters, and in this way reduce the investment cost of the current-distribution system. The distance covered by the feeder systems for locomotive haulage is more than 148 miles, while the transmission distances from the turbo-generator stations total about 35 miles.

One of the most important applications of electricity in these mines, aside from



Curtis Turbine Generators, Hampton Power Plant, Scranton, Penn.

that of mine haulage, is found in the use of electrically driven hoists. For these, both alternating- and direct-current motors are used. There are 27 of the former type, having a total capacity of 3570 hp., and 25 direct-current motor hoists, taking about 2420 hp.; an aggregate of about 6000 hp. is required for this class of service.



Switchboard, Hampton Power Station

Pumping Service

The notable improvements in the design of centrifugal pumps during the last few years have resulted in numerous installations in the mines under consideration, both for auxiliary pumps and for operation at the main sumps. As in the case of the hoists, both alternating and direct-current motors are used, although, due to the characteristics of the induction motor, all the newer stationary pumping sets are driven by alternating-current machines. These with their high efficiency at constant speed and uniform load, are peculiarly adapted for the operation of centrifugal pumps.

There are 46 alternating-current motors, aggregating 5670 hp., used in pumping service, and 48 direct-current motors, with a total capacity of 1400 hp., used for driving pumps of both the centrifugal and plunger type. Most of the direct-current sets are small auxiliary units, and a number of them consist in 300-ft.-head portable plunger-pumping outfits mounted on trucks, which can be hauled to various locations in the mines and operated from the locomotive feeder wires.

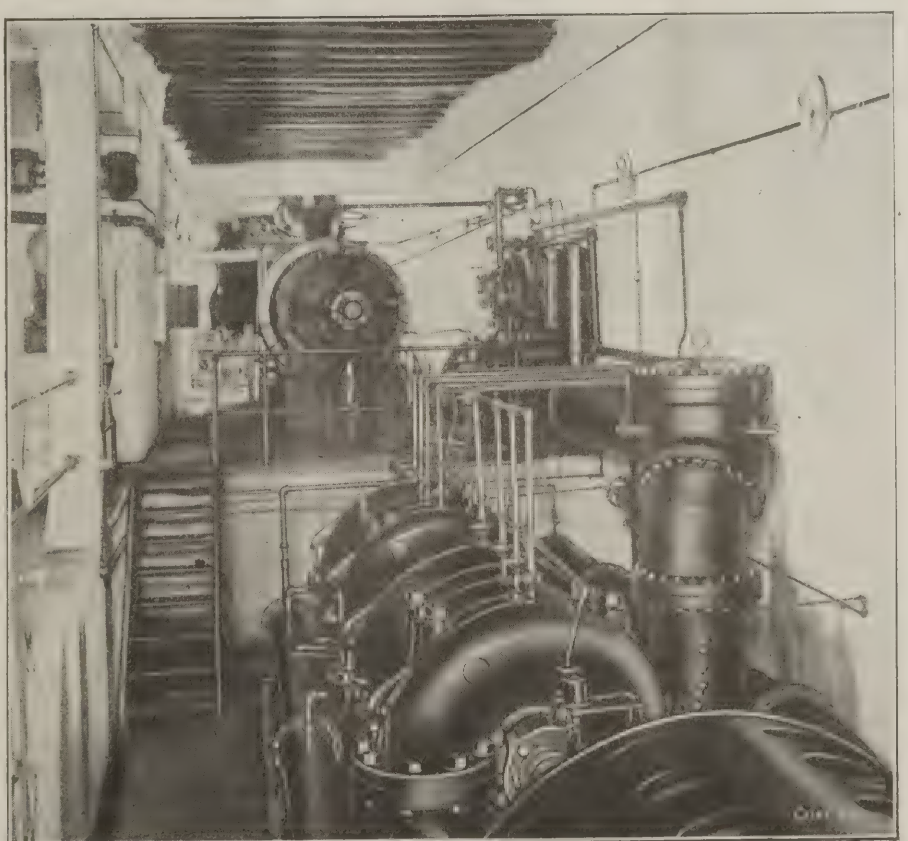
In addition to the motor-driven water-hoisting equipment, the sump at Hampton is served by two six-stage centrifugal pumps operating at 720 r.p.m. against a 500-ft. head. Each pump delivers 5000 gal. per min., and is directly driven by a 1000-hp., 2300-volt induction motor. Inasmuch as these two centrifugal pumps and the water hoist represent a total demand of 2800 hp., they constitute a most important factor in determining the peak load of the Hampton generating station, and for this reason they are normally operated at night, the sump being of sufficient size to take care of ordinary drainage during the day time. As the demand on the power station diminishes toward the end of the working day, the load on the generators is brought up to approximately normal level by successively throwing into service the two centrifugal pumps and the water-hoisting outfit.

The water which is elevated from the Hampton sump is utilized in various ways before it is discarded. It first passes to a reservoir where it is used for the operation of barometric condensers in connection with the steam-turbine plant; and from the condensers it passes to a washery, being thereafter used for slushing ashes, crushed rock and other mine refuse through bore holes into worked-out sections of the mines.

Breaker Drives and Auxiliaries

In addition to those already enumerated, there are 127 alternating-current motors, aggregating 530 hp. in capacity, and 12 direct-current motors, totalling 225 hp., that are used for auxiliary service at the mines and collieries. Fifteen of these are employed to drive rock crushers, by means of belt drives, and a number are belt-connected to fans, although most of the ventilation in these mines is still carried on by means of engine-driven fans.

An interesting application of individual motor drive is found in three of the breakers operated by the Lackawanna company. These are equipped with induction motors, direct-connected to various driving shafts, thereby minimizing the number of belts required, and reducing the friction losses inseparable from the operation of breakers by means of



Six-stage Motor-driven Centrifugal Pumps

steam engines. Individual drives for these breakers were adopted about seven years ago, and their efficiency is indicated by the records of the Truesdale breaker, which handles between 3500 and 4000 tons per day with a power consumption of approximately one kilowatt-hour per ton of coal, including the hoisting of the coal to the top of the breaker.

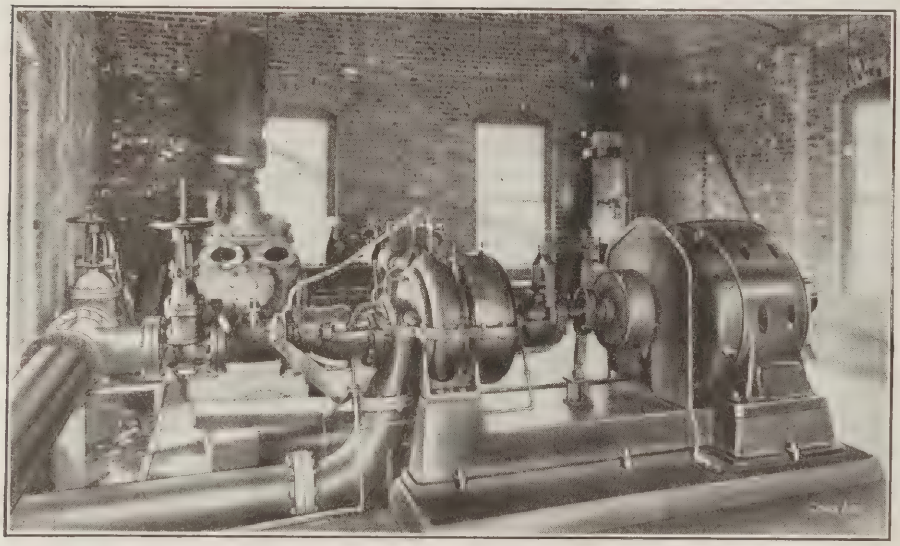
The extent to which electric drives have been adopted at these collieries is shown by the following list of aggregate motor capacities:

	Hp.
Direct-current locomotives	10,750
Alternating-current hoists	3,571
Direct-current hoists	2,420
Alternating-current pumps	5,670
Direct-current pumps	1,402
Alternating current, miscellaneous	3,580
Direct current, miscellaneous	225
Total, alternating current	12,821
Total, direct current	14,797
Grand total	27,618

third of this being required for the breaker.

The local current distribution and control are provided for by means of a switchboard containing a totalizing panel, and feeder panels for the various alternating- and direct-current circuits.

There are 16 locomotives in operation at this colliery, having a total capacity of 1150 hp., but, as they constitute an intermittent demand, the 500-kw. rotary converter is of ample capacity for their operation, and in addition it serves five motors with a total rated capacity of 937 hp. for driving car hoists on slopes. When the day load diminishes, the direct-current equipment is switched over to the 200-kw. rotary converter, which was originally of ample capacity to carry the entire load, but is now normally held for night operation or emergency service.



Two-stage Motor-driven Pump, Truesdale Washery

Truesdale Colliery

The electrical equipment of the Truesdale colliery will serve as a typical example of the substation practice of the coal department of the Delaware, Lackawanna & Western R.R. Co. Power is transmitted at the generator voltage from the Nanticoke station and received at a transformer substation located at the colliery. The substation equipment includes stepdown transformers and two six-phase rotary converters, one of 200 kw. and one of 500 kw. capacity. The current, which is received at 4150 volts, is stepped down in the transformers to about 200 volts for the operation of the rotary converters, and separate transformers supply 440-volt circuits for the induction motors.

Steam is still used at Truesdale for hoisting in the shafts, operating ventilating fans and heating the breaker, but all other operations are carried on electrically. The total current consumption averages 12,000 kw.-hr. per day, about one-

Of the 13 pumps at this colliery, which have a total capacity of 610 hp., all but one are located in the mines. The track or portable pumps are driven by direct-current motors, while all stationary units are of the induction motor-driven centrifugal type.

Three 250-kv.-a. 4150- to 440-volt transformers are provided for the alternating-current circuits on which 30 motors, with a total capacity of 700 hp., are operated. Most of these are used for individual drives in the breaker and the remainder operate the conveyor lines, a rock crusher and ventilating fan.

In the operation of the breaker improved working conditions have been attained by the installation of a 75-hp. motor, which drives an exhaust fan for clearing the breaker of dust.

Improvement of Power Factor

Owing to the number of induction motors used at this colliery, the question of maintaining a high power factor is an important one, and it has, therefore, been decided to substitute a 100 kv.-a. synchronous motor for the 75-hp. induction motor now driving the fan. This will mean that the synchronous motor will be loaded to approximately 70 per cent. of its capacity, and the necessary leading current for raising the power factor locally will be most economically obtained.

Practically all the transformers used in this equipment are three phase, 60 cycle. The cables are carried into the mines through bore holes or down the hoisting shafts where they occupy space that could not otherwise be utilized. The electrical apparatus described above was supplied by the General Electric Co., Schenectady, N. Y.

The Fuel Situation in California

Oil is used almost exclusively in the state of California for the manufacture of gas and, with a few exceptions, for generating steam in stationary plants, railroads and on the coast steamers. The bulk of the ocean steamers trading regularly at San Francisco, San Pedro and San Diego are also equipped for oil burning. Also the Southern Pacific, Union Pacific, Santa Fé and Western Pacific railroads use absolutely no coal on their Pacific Coast divisions; consequently this latter fuel is practically eliminated as a factor in steam producing and its use at the present time is confined almost entirely to household requirements.

To meet this demand, since there is no local coal, other than a second-grade lignite, this market is entirely dependent on foreign and Rocky Mountain coals. Twenty to thirty years ago considerable house coal was imported from Great Britain, chiefly English Cannel, Scotch Splint and Westminster Brymbo, but since the opening up of the British Columbia coal fields the bulk of the domestic fuel has come from that source. For the past ten years a high-grade domestic coal has been imported from Australia which has found solid favor in this market. The f.o.b. price of this coal is now, and has been for the past five years, $2.70 per long ton, and its delivered value is naturally dependent on fluctuations in freight rates.

Accurate data as to Rocky Mountain coals coming in by car are unobtainable, but there is little doubt that it is making considerable headway, especially the Wyoming and New Mexico products; this is due to their cleanliness and comparative freedom from soot and also to the high prices of the British Columbia and Australian products which ruled in this market for some time.

Never hook a trolley feeder around a trolley clamp. This practice, common in mines, is a sure source of trouble as they are almost certain to work loose.

Some Coal Statistics for 1911

Special Correspondence

Some of the more important statistics of fuel production and transportation for the year 1911. The volume of coal handled as a whole shows little change over the previous year. A new high record was established in anthracite, while the coke industry showed a falling off in sympathy with the curtailment in the production of pig-iron.

Note—Excerpts from the "Monthly Summary of Commerce and Finance," including the completed statistics for 1911.

The volume of coal traffic during the past year, as reported by the leading Eastern coal-carrying railroads, shows but little change from the high figures of the preceding year. The same is not true of the coke movement, which, in sympathy with the curtailment of pig-iron operations, shows a considerable decline.

The anthracite coal shipments from Eastern producing territory aggregated during the past year 69,954,299 long tons, the largest annual total recorded during the past decade, and exceeded by over 5,000,000 long tons the high record of the preceding year. Over 20 per cent. of the total shipped, namely 14,651,441 long tons, was handled in and around New York for shipment to New York proper or to New England destinations. Coastwise shipments of anthracite from Philadelphia during the past year totaled 2,197,750 long tons, while similar shipments from Baltimore are stated as 257,025 long tons. The domestic Lake shipments of anthracite coal during 1911 amounted to 4,374,100 short tons, of which 4,074,383 short tons proceeded from Lake Erie and 254,419 short tons from Lake Ontario ports, the 1911 shipments by Lake showing about the same rate of increase as the total and coastwise movements.

The movement of bituminous coal, as reported by 12 leading Eastern coal-carrying roads, totaled 144,623,992 short tons in 1911, as compared with 141,901,097 short tons in 1910 and 122,057,662 short tons in 1909. Coastwise shipments from the five principal Atlantic seaports totaled 26,986,348 long tons in 1911, compared with 25,835,029 long tons in 1910.

Of the total for the year, 10,749,988 long tons are credited to New York, 4,856,626 long tons to Philadelphia, 4,002,809 long tons to Baltimore, 2,678,156 long tons to Newport News, and 4,698,769 long tons to Norfolk, all the ports except Newport News showing larger figures for 1911 than for the preceding year. The largest relative gain of over 1,000,000 tons is reported by Norfolk, and is due mainly to the increase in tidewater shipments by the Virginian Ry. from its Sewell's Point piers.

The Lake shipments of soft coal for the past year, 17,081,355 short tons, show a considerable shrinkage from the 1910 figures of 18,406,469 short tons. It should be remembered, however, that the demand for soft coal at the upper Lake ports in the year 1910 was exceptional, owing to the shortage in the supply of Ohio, Indiana and Illinois coal during part of the year, as the result of the miners' strike. As a matter of fact, the 1911 shipments by far exceed those of any previous year except the year immediately preceding.

The coke movement from the Connellsville district in 1911 is reported to be 16,334,174 short tons, compared with 18,689,722 short tons shipped in 1910 and 17,785,832 short tons shipped in 1909. The number of active ovens reached its maximum about the second week of April, when out of a total of 39,399 ovens 28,514 were in blast. Since that date the proportion of active ovens has varied between 60 and 70 per cent., being about 68 per cent. at the end of the year.

STATEMENT OF THE OHIO COAL TRAFFIC ASSOCIATION FOR DECEMBER AND THE YEARS 1910–11 IN SHORT TONS

Railroads	December		Year	
	1910	1911	1910	1911
Hocking Valley	475,500	315,268	4,777,478	3,621,794

Our Noncontiguous Possessions

The following is a comparative statement of fuel shipments to the noncontiguous territories of the United States for the years 1910-11, in long tons:

	1910	1911
Alaska (coal)	28,659	28,799
Alaska (coke)	174	261
Hawaii (coal)	61,655	1,713
Porto Rico (anthracite)	3,035	2,414
Porto Rico (bituminous)	105,070	101,385
Philippines (bituminous)	118,389	

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

New Safety Catch for Cage

The following is a translation of an article by Guido Nirtl, superintendent of the Austria Shaft III, near Karbitz, Austria, and extracted from the *Zeitschrift des Zentral-Verbandes der Bergbau-Betriebsleiter*.

The idea which led me to the design of my safety catch for cages was to make a mechanism which, in contrast to those at present commonly used, would be entirely independent of the hoisting rope, and which would act not only if the rope should break, but also should the cage attain more than a certain maximum velocity in descent. My catch depends on the resistance which the air opposes to a rapidly moving body.

The plate A, lying free at the bottom of the cage, will be raised up when a certain velocity, which can be chosen at leisure, is exceeded. The plate will thus strike against the latches B and C, whereby the springs are released and the catches are made to engage.

The theoretical basis rests on the following calculations: The air resistance in a shaft is

$$R = 0.000531\, Sv^2$$

in which S is the surface moved in square feet and v the hoisting velocity in feet per sec. at that time. To take a convenient example, I choose:

$S = 1$ square foot;
$v = 45$ ft. per sec.;

so that we get

$R = 0.000531 \times 1 \times (45)^2$;
$R = 1.075$ lb. per sq.ft.

A plate which weighs 1.075 lb. per sq.ft. would, therefore, be balanced by the air resistance if it attained a descending speed of 45 ft. per second.

The construction of the safety-catch mechanism is as follows:

It should first be stated that the mechanism for restraining the fall of the cage is placed not, as is now general, under the roof, but under the cage bottom.

A rectangular frame of channel iron is fast connected to the cage bottom, and on this, the iron plate A lies free, being merely guided when it lifts by the four guide rods D.

Four eccentric catches E are placed outside, below the cage bottom. Each pair is joined by an eccentric rod F, which can turn in the bearings G. On each of the eccentric rods are keyed two crank pieces H, which are linked with the crossheads I by connecting rods J, which are keyed to the crossheads. Through the crossheads pass the piston rods K, which belong to the movable pistons L, traveling in a wrought-iron cylinder M.

The ends of the two piston rods form engaging blocks N by which, through the latches B and C, which can turn in the bearings O, these piston rods are so pulled that the pistons hold in compression the buffer spring P in the cylinder, making them press against the cylinder heads.

If now, as already suggested, the hoisting-cage safety catch comes into action through the plate A being raised by the air resistance and brought against the latches B and C, then the piston rods are unlatched, the pistons thrust together by the liberated springs, and the eccentric rods, by reason of their connection with the piston rods, are compelled to turn through a certain angle, whereby the eccentric is made to press into the guides.

The movement of the latches is seen in Fig. 3; that of the pistons and eccentrics in Fig. 2.

The compression of the spring after each action of the safety device is performed by auxiliary cords fastened to the piston rods and passing over the rolls Q, and over similar rolls below the cage root and connected with the hoisting rope. By the tension of the hoisting rope, the auxiliary ropes are tightened, and with them the springs.

For the regulation of the compression of the springs, the piston rods are connected to the crossheads by a screw thread, the middle part of the crossheads

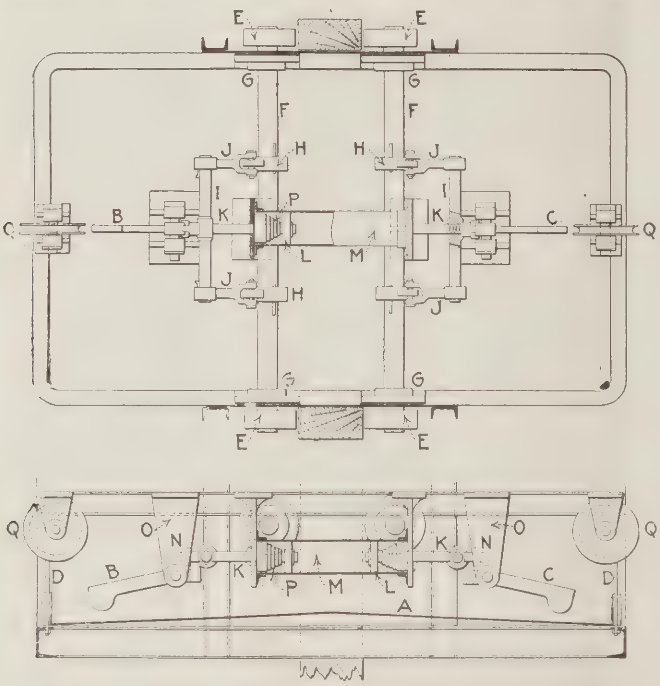

Fig. 1. General Arrangement of Safety Catch

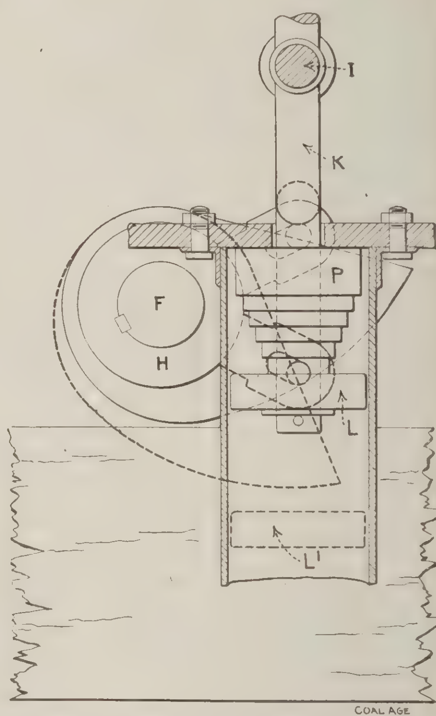

Fig. 2. Pistons and Eccentrics

forming the nuts in which the piston rods can be turned.

The advantages of my construction are as follows:

1. It removes the uncertainty connected with safety catches that are actuated by the breakage of the rope, that is through its relaxation of tension. 2. Joints are avoided, so that a failure to act by reason of foulness is prevented. 3. The springs are inclosed in a cylinder, so that they are protected from external influences, especially dirt. 4. The safety catch consists of two entirely separate halves. If, therefore, through breakage of the spring or other part, one half refuses to act, the other half will nevertheless take hold. 5. The entire construction is simple and easy to inspect, also easy to control, and it can be applied to any existing cage. 6. The prescribed tests of its action can be made simply by bringing the cage down on a post, whereby the bottom plate is raised and the entire mechanism made to act.

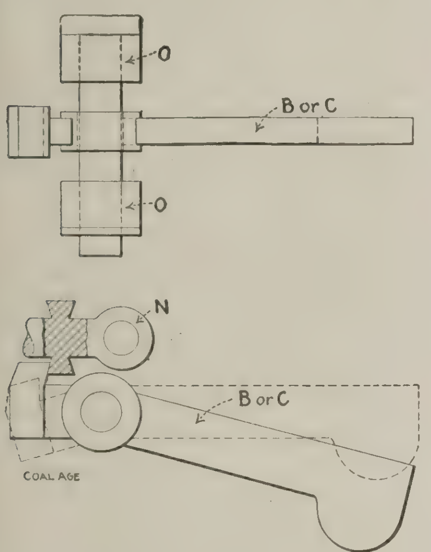

Fig. 3. Latch Movement

Plates of different weight can readily be adjusted to the bottom of the cage, so that the speed limit may be suited to varying conditions. Adjustable valves could be placed in the plate *A*, and by these speed at which it would act might be regulated.

This safety catch of improved design could be used when hoisting men in addition to the ordinary safety catch, so as to provide increased security. When hoisting material, the plate can be fixed by an appropriate appliance, so as to be temporarily out of service. Tests of its principle, which already have been made, have given good results.

The general manufacturing right on this hoisting-cage safety catch has been acquired by the "Erste Brüxer Eisengiesserei, Kesselschmiede und Maschinenfabrik in Brüx."

Natural Oil in Coal Mines

When the Yorkshire section of the Society of Chemical Industry held a recent session at Leeds, J. B. Cohen and C. P. Finn read an article on "Paraffins from a Yorkshire Coal Seam," from which we have abstracted the following observations:

"About three years ago, our attention was drawn to a curious oil which dripped from the roof of the Haigh Moor seam, of the Hemsworth collieries. This oil, it was stated, had been running for about seven years, and at one time there was such a quantity that the workmen had been in the habit of using it as a lubricant. It was further stated by the officials who were connected with the colliery before it was sold to its present owners, that when a road was driven through the place mentioned, what they expressively described as 'balls of vaseline,' were found. As the flow at this time (1908) was slow, arrangements were made to collect a supply of the oil, but a fall of roof caused the breakage of the collecting vessels, and as the place had to be timbered up, the opportunity was lost.

Oil Oozed from Fault

"A description of the position where the oil was found will be of interest. The two shafts of the Hemsworth collieries pass through several seams of coal, the principal being the Shafton, Barnsley and Haigh Moor beds. At present only the two last mentioned are being worked, at depths of 1839 ft. and 2058 ft., respectively. A fault is observed in all these seams. Its maximum throw is only 11 ft. The oil was found in the Haigh Moor seam, at a place where the road from the pit bottom crossed the fissure of the fault. This was at a depth of about 2070 ft. from the surface, and in a bed of bluestone bind, part of which contained ironstone bands and was interstratified by a white, soft and permeable sandstone rock. At first sight, it seemed that the oil had an origin in some stratum above the Haigh Moor seam, and that it had come down the fissure of the fault. As it was not found in the Barnsley seam, it possibly came from the strata near or below that bed.

"Early in 1911 it was decided to drive a drift, which would cross this fault in another place. While this was being done, a careful watch was kept for any possible flow of oil. The expectations were fulfilled, and where the drift crossed the line of fault, the surrounding strata were found to be saturated with oil. The oil as it ran out was of a yellow color, but turned a dark brown on exposure to air. No evidence of any natural gas was found.

"Previously recorded instances of oil occurring in the coal beds of Great Britain are few outside of the historic find by Young near Alfreton, in Derbyshire.

Briceville Disaster

Joseph A. Holmes, the director of the Bureau of Mines, addressed the Southern Appalachian Coal Operators' Association, at Knoxville, Tenn., Feb. 13, on "Some Lessons from Recent Mine Disasters." After reviewing the subject of mine accidents in general, in referring to the recent Briceville disaster, he said:

"There should be at every mine or group of mines a sufficient number of men equipped with breathing apparatus, who can begin rescue work in a mine as soon as a disaster occurs, with the expectation of being relieved or aided when other rescuers arrive.

"The more training and experience a miner has in this new type of rescue work, the more efficient he becomes, and the more he can accomplish within a given space of time; and the less is his risk of losing his life. But even after a week's training, such as is given by the government mine-rescue car, a miner should be further trained if he is to take part in the actual rescue work following a mine disaster. Under no ordinary circumstances should a man who has had no previous training in wearing the helmet and its outfit make a trip to a remote part of the mine filled by poisonous gases. This should be done only by men who have already had training for at least a week.

Helmets of No Value to Untrained Men

"The number of men trained and supplied with modern rescue equipment should be rapidly and greatly increased in every important coal field. It is hoped that within a few years more, this system will be developed to such an extent that should such a disaster occur as that which happened at Briceville, within a few hours after its occurrence there can be assembled on the ground from 50 to 100 men, who are well trained and fully equipped with special breathing apparatus; and who are also fairly familiar with the immediate mining district.

"With a force of this kind it would be possible, within a few hours, to reach all the remote portions of the mine. With the present limited number of trained men in different parts of the country, this is impossible. At no disaster previous to that at Briceville, have we been able to bring together within a short time as many as a dozen experienced and well equipped men. For a short time at Briceville, there were as many as 20 men who had some training in the use of helmets, but one half of these were without experience in actual rescue work, and not one of them was familiar with the mining conditions in that region. A week was therefore required to accomplish results, which should have been accomplished in less than 24 hours."

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

There is one other man who knows as much about mining anthracite coal as does our friend Sam D. Warriner, but I have forgotten his name and can't remember his address. And right here let me remark that "S. D." is a living, forceful, convincing refutation to the popular idea that no man hampered with a university training can carry this burden and at the same time climb the ladder to success.

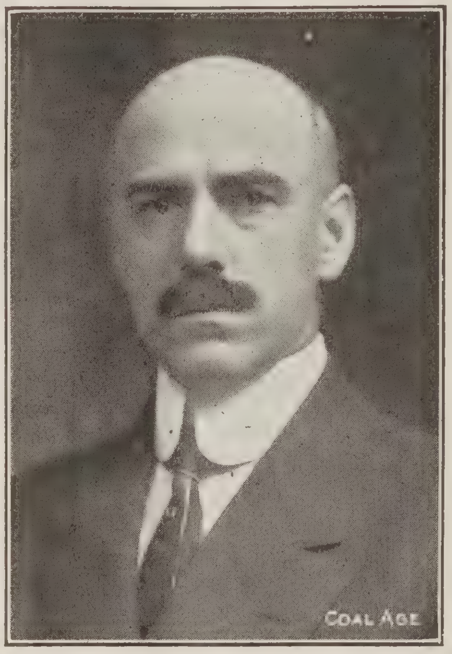
Of course, I don't mean to insinuate that it's as easy for a fellow to succeed when he has been loaded down with a college degree, as when his handicap in the way of an education has extended only as far as elementary algebra in the red school house on the village green. Nor would I have you believe that a sheepskin signed by the president of a great university is equal in value or force to the diploma carefully deposited on your right jaw and bearing the signature of the left hind hoof of a husky pit mule. In truth, it's a fact that some managers owe their running start as well as their later rapid advance to the vigorous reactionary tendencies of an argumentative mine mule.

However, in defiance of revered tradition, and despite adverse odds in the form of a professional training supplied by an indulgent father, who, by the way, was a country minister, Mr. Warriner has measured up to expectations ana smashed all time records in getting to the very front of the procession.

Living up to the idea that, "champion once in one thing, champion always in everything," he has pitched curves around the heads of his competitors, just as he used to deliver fadeaways when occupying the box on the Lehigh University ball team. And with "S. D.," this matter of being a champion isn't confined to some specialized line of effort; with him it's wholly a question of season and style. I haven't the slightest doubt but that he would make as good a blacksmith, ping-pong player or ambassador as he is coal-mine manager.

Fancy a sitting of the anthracite conciliation board with Warriner pitching and Richards, of the Reading Company, catching. Can you imagine there would be many base hits on the part of the representatives of the Union? Someone told me a short time ago that the batting average of the miners on the board during the past decade figured out at minus twenty-three.

After graduating at Amherst, Sam Warriner took his E. M. degree at Lehigh in '90. No time was lost in useless meditation, and a few weeks later, he was busily occupied mining iron ore down in Virginia. No man is half an engineer today unless he has mined iron ore in Virginia, gold in North Carolina, or coal in California.



SAMUEL D. WARRINER

"S. D.'s" stay south of the Mason-Dixon line was limited, and before a year had passed he was back in Pennsylvania acting in the capacity of mechanical engineer for the Lehigh Valley Coal Co. Under the tutelage of that "maker of mine managers," W. A. Lathrop, Mr. Warriner advanced rapidly, and before leaving the anthracite field to take charge of development work at the Calumet & Hecla copper mines, in Michigan, he had won recognition as a clever engineer.

The years spent in Northern Michigan with the "C. & H.," furnished Sam Warriner the opportunity to prove his worth. That he discounted and cashed all chances, and at the same time sailed true to the compass, was evidenced by his being called back to Wilkes-Barre, to succeed Mr. Lathrop as general manager of the Lehigh Valley Coal Co.

Some twelve years ago, when Mr. Warriner thus returned to his first love, President Walters, of the Lehigh Valley, said: "As for those coal mines of ours, Sam, if you can only wipe out the annual deficit and split even on the deal, we'll be mighty pleased with the result." Suffice it to say, that last year the coal department of the Lehigh Valley earned a little more than 100 per cent. on its capitalization, and although the latter is small ($1,250,000), the progress made in a dozen years is quite remarkable.

I have hesitated all through this little story to start talking about Sam Warriner's head, and I am afraid now if I commence to write on this subject, the remainder of the page will be quickly filled. However, a sketch of "S. D.," without some remarks concerning his "thought factory," would be as incomplete as a picture of Theodore Roosevelt with mouth closed and teeth invisible.

The fellow who first remarked about a long-headed man was looking straight at Samuel. His forehead begins at his eyebrows and ends on the back of his head just above his collar. His thoughts have been so intense and so frequent in recurrence, that only one hair, which the artist has failed to bring out in the accompanying photograph, remains as a silent monument to the fact that other hairs once resided in the same vicinity.

Mr. Warriner's head would be the delight of phrenologists. Nothing could he hide from them when his hat was off, although it's a notorious fact that in everyday life he has been able to hide all things he didn't want the other fellow to know. Of those matters in which "S.D." is proficient, the art of listening is strongest developed, and if "silence is golden" then Samuel is a mint. Years ago he read the proverb, "A Quiet Tongue Shows a Wise Head," and the thought so impressed him, be became chief exponent of the idea in practical life.

Of all Mr. Warriner's opinions, none is more interesting than his belief that welfare work must be coöperative on the part of the company and the men. He says any other plan robs the men of self-respect and creates paupers.

In conclusion, let me say there is one sure way to make "Sam D." speak, and that is to mention the "check-off" system the miners are now demanding. If you think the subject of this sketch lacks in determination, or has any ring in his nose by which he is led, just watch the positive, direct-connected action of his jaws when he replies: "We'll close our mines forever before we agree to any such principle." And even when you have thus touched Sam on this particularly tender spot, his eyes are quiet and a little cold, in no way showing the fire that smoulders underneath. This ability to disguise every feeling is the most noteworthy characteristic of the man.

Issued Weekly by the

Hill Publishing Company

John A. Hill, Pres. and Treas. Rob't McKean, Sec'y.

505 Pearl St., New York.
6 Bouverie St., London, E. C.
Unter den Linden 71, Berlin.

Correspondence suitable for the columns of Coal Age solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Entered as second-class matter, October 14, 1911, at the post office at New York, New York, under the act of March 3, 1879.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of Coal Age, we will print 7000 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.

This journal has a direct aim—a single purpose—which is to help advance the coal-mining industry. Its creed embodies the dissemination of knowledge and the free interchange of ideas among its readers, all of whom are invited to become regular contributors.

Contents

COAL AGE

What a Strike Will Mean

Should both the anthracite and bituminous operators and miners fail to reach an agreement by April 1 the largest industrial suspension in the history of the country will be precipitated. The anthracite and most of the bituminous agreements expire simultaneously at this time, and approximately half a million men will be immediately affected. Through the curtailment in fuel supplies, and consequent restriction of operations at steam plants generally throughout the country, more than twice this number of men will be indirectly affected in a comparatively short time.

If the labor leaders control the situation to the extent they claim, and there are no reasonable grounds for belief to the contrary, 64.5 per cent. of the productive capacity of the country would be affected. In this estimate is included the entire state of Pennsylvania, with the exception of the Connellsville region, Ohio, Indiana, Illinois, and the Southwestern district, including Missouri, Kansas, Arkansas and Oklahoma. The Central district of Pennsylvania and the state of Iowa are not in the tri-state agreement, and while the former may possibly reach an independent settlement and continue at work, the latter will doubtless be governed by the results of the tri-state convention.

Of the remaining 35.5 per cent. unaffected by the strike, only 23.6 may be regarded as accessible to the markets supplied by the union mines. This includes the Connellsville district, West Virginia, Kentucky, Tennessee and Maryland. In event of urgent demand, some of the Alabama fuel might reach portions of the affected area, but with its total production of only 3.2 per cent. the amount would be negligible. The Rocky Mountain States, with their production of 5.7 per cent. of the country's total, may be regarded as too remote to offer any relief to a shortage in the Eastern markets.

The possibilities of obtaining assistance from foreign countries are *nil*. With the British miners out, and the German production seriously curtailed, the European stocks are being depleted, and in any event, sufficient coal could not be transported from those markets to be of material assistance. Local points along the north Atlantic coast will no doubt obtain some relief from Nova Scotia, but with the entire Canadian production equal to only 2 per cent. that of the United States, this will not affect the situation in general.

From this summary it seems fair to assume, as stated, that only 23.6 per cent. of our productive capacity will be available to supply markets with a consumption of 64.5 per cent. Nor can this 23.6 per cent. be regarded as surplus coal since there must already be a natural consumption for it, and only the overproduction will be free for use in other markets. In view of the well known and deplorable conditions existing in West Virginia as a direct result of over-production, and the extensive developments recently inaugurated in the Kentucky fields, we venture to assume that, under pressure, this 23.6 per cent. output may be doubled, leaving that amount available for other markets, and reducing our total fuel shortage to 40.9 per cent. What the effect of a forced reduction in fuel consumption of 40 per cent. will be on the industrial world remains to be seen.

From a monetary standpoint, the possibilities are even more alarming. For each working day our fuel production is curtailed 40 per cent. the miners will sustain a loss in wages of eight hundred thousand dollars. On the same basis the value of the product at the mine per working day is one million two hundred thousand dollars. This is the real loss which the industry will sustain if a suspension occurs.

It is not within the scope of this journal to pass judgment on the comparative merits of the issues under contention. But it is within our province to urge upon the contending principals the grave responsibilities of their position and the national importance of their deliberations. Labor has learned an important lesson from syndicated capital with its interlocking di-

rectorates, alliances, etc.—and has, in fact, become syndicated labor, with a latent brute power of passivity no longer denied. And between labor and capital there is a third, and entirely helpless and innocent party, who must eventually pay the enormous bill—the public.

In conclusion, we wish to express the belief that a national coal strike in this country is unlikely. Work in either the anthracite or the bituminous field may be suspended, but the chances of a shutdown in both branches of the industry are remote. The hard-coal operators will never consent to the check-off system demanded by the miners, and, for this and other reasons, it is probable the chief trouble will take place in the anthracite districts.

Coal Mines and Health

Some time ago Coal Age published a series of articles by Edwin M. Chance, entitled "Pathogenic Mine Atmospheres." Before publication, the title was carefully considered and finally the decision was made that as the caption was a brief of the original title under which the paper thus abstracted was read before the Franklin Institute, it would be well to retain the word "pathogenic" of the original manuscript, using the word in about the same sense, for instance, as it was used by Hahnemann and the original homeopathists.

In former years, the word "pathogenic" lay, in recognized usage, nearer its Greek origins. Later bacteriologic research which has absorbed the brightest thought of modern students of disease has made the word slip its anchor and it is less often used today than formerly to express broadly all forms of the quality of causing suffering. The average present day practitioner would in common parlance limit its reference more specifically to the quality of carrying germs, which have a distressing effect on the human organism. Thus we term the air exhaled by consumptives, the defecations of typhoid patients and the sloughings of those who suffer from small-pox, pathogenic bodies. Many harmful yet germless mediums are not regarded, in the modern sense, as pathogenic at all. They are called poisons, mild or severe. Few would now regard salicylate of soda, for example, as a pathogenic substance. So that viewed from this new standpoint, we would be inclined to state that the mine atmosphere is not pathogenic. It is rather germicidal as is the drug just mentioned.

It is customary to represent the mines as prejudicial to the health of the miner. We have never been able to accept that dictum in its application to American mines, which are not deep and therefore not warm. The heat of our mines is not sufficient to aid the growth of such germs as will thrive in the blood warmth of the human body. Those impurities which the air contains are usually harmful only as they create in the blood undesirable chemical conditions, or as they dilute that constituent, oxygen, on which the health of the human organism depends. In fact some have suggested that a slight depletion of oxygen has its advantages and may have a marked deleterious effect on certain micro-organisms which have a narrower range of accommodations to atmospheric change than is possessed by man.

The higher altitudes where the density of the air is less than at sea level are favorable to consumptives. Whether the relief they afford is mainly due to the physiologic effects on the patient or to like effects on the patient's deadly enemy, we do not know, nor does it concern us, but if the effect of rarefaction of air on the consumptive depends on the reduction in the oxygen density, we can readily see some justification for those who do not look with disapproval on slight depletions of that constituent.

The miner has always declared the mines unhealthy. Much the same has been said on the dangers of night air. A century past, sea air was also declared extremely unhealthy and the rich recuperated at inland watering places. The rugged health of the sailor might have borne witness to the contrary, just as the miner is a living confutation today of his own ill considered theories. But all evidences were long unheeded; the thrice-breathed indoor air and the heavy air of closed-in valleys were preferred. Yet today nearly everyone sleeps with open windows and crowds of health seekers throng the seaside boardwalks. The time is coming when we shall view the average mine, above sea level, as dangerous indeed to life and limb, but not biochemically unfavorable to the happy continuance of life and health in the animal organism.

We have heard almost all hygienic ills, thoughtlessly attributed to the mine water, coal dust and the mine atmosphere. An evil looking trinity it must be admitted they make, yet if you attack the coal miner's statement he will nearly always begrudgingly admit that his fellow workers are really not unhealthy and are subject less to rheumatism and consumption, for instance, than men in other occupations. As a matter of fact, hard as it may be to explain, neither of these ills, to both of which one would, *a priori*, expect him to be subject, often afflict the coal miner.

With lungs filled with dust, stooped by shoveling, greviously cramped in undermining, often doubled like a jackknife for eight long hours, the coal miner nevertheless resists consumption well. Working in water, in a continual draft of air, making long tramps from the mines to his home with his clothes frozen stiff over his body, we may be sure that differences of temperature in two adjacent parts of his skin must occur and this thermal inequality is by many thought to be if not the primary at least the accessory cause of rheumatism.

The miner is also subject to frequent skin abrasions. Dirt is an essential part of his toil and this dirt enters his wounds and though in the open air these conditions favor the pus-forming germs, no such results appear to follow in the mines. Not only do trifling abrasions heal without painful complications, but it has been noted by M. J. Shields of the American Red Cross Society, and the conclusion has been fortified by his diligent inquiries, that major accidents with accompanying crushings and manglings never result in lockjaw unless the injured mine workers are hurt in underground stables.

The air, the coal dust and the water which are the three ills confronting the coal miner are all probably rendered antiseptic by the pyrites in the coal. This pyrites turns to iron sulphate by oxidation, dissolving in water; reactions take place precipitating ferric hydrate and leaving the water impregnated with sulphuric acid. This evaporates slowly and the vapor probably renders the air and coal dust germicidal.

Small quantities of nitrous fumes from some explosives add a trifling amount of nitric acid to the air, though the comlete combustion of blasting powder and nitroglycerin does not exhibit such an action, the nitrogen being freed entirely.

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Shot Firing in Mines

(*Continued from March 9*)

Letter No. 4—In answer to the question from Seanor, Penn., regarding the disadvantage in the simultaneous firing of shots, I do not believe there is any disadvantage. Also the article on page 642, by W. Hartman, in which he states that electrical firing is more complex and expensive than by the old fuse method, seems exactly opposite to my experience.

In the first place, I have found it far easier, and quicker, to punch a hole in the dynamite, insert the wired detonator, than to peel off the fuse, slip the cap over the end, press it on, and then tie up the package. From a standpoint of cost, it certainly is far cheaper to fire with an electrical detonator than to buy, say, 10 ft. of fuse and a cap, the combined cost of which is far greater than an electric detonator to do the same work.

There may be a remote possibility of danger in the simultaneous firing of shots, providing the charges were extraordinarily heavy. This would be due to the interruption of the ventilating current, the compression and reaction tending to disturb the gas in the gob, and also displace doors, brattices, loose roof, etc., in the same manner as a small explosion.

There are several advantages in simultaneous firing, among which are greater safety to the miner, as he is sure the shots will go off at a certain time, and that there will be no "hang fire" caused by "kinked" fuses.

It is also safer from a standpoint of dust and temperature. If shots are fired in rapid succession, the first makes a certain amount of dust and a certain increase in temperature; the second results in two volumes of dust and two increases in temperature, and the firing goes on until we have dust and heat conditions which are ideal for an explosion.

Shots fired simultaneously perform greater work than when fired separately, that is, their efficiency is increased, and their yield in coal almost double. Therefore fewer drill holes are required, not so much powder, and there is less smoke, time and expense.

Summing it all up, I am of the opinion that the simultaneous firing of shots has all the advantages, and none of the disadvantages of the fuse and cap system of firing.

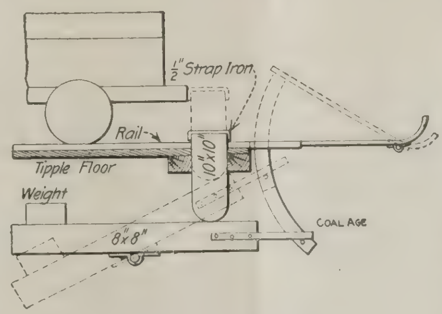
Johnstown, Penn.

A Novel Safety Device for Tipples

I hand you herewith sketch of a stop I have applied to a tipple which I find works satisfactorily and has saved me considerable time and delays by runaway cars striking the sword of the tipple dump. I believe the sketch is self-explanatory.



Sketch of Car Stop

When the dump is in a dumping position, the block is raised so that it will catch the bumpers of the car. When the dump is released to receive another car the block falls back in place. It is not an expensive construction, as it can usually be placed on timbers used for the construction of the tipple. By having the 8x8-in. timber properly balanced it does not interfere with the dump in any way.

Seismic Unrest and Falls of Roof

The editorial on danger periods in mines, in Coal Age, Dec. 16, was highly interesting and recalled some suggestive coincidences in the possible existing relationship between seismic disturbances and coal-mine holocausts, a matter upon which scientists and coal-mining authorities generally are divided.

It would appear that the evidence so far collected is regarded as being not quite sufficiently convincing to convert the entire community to this theory. However, whereas only a few years ago the bare mention of the possibility of such a connection was openly ridiculed, the correlation of certain facts, has resulted in the adherence to the seismic theory by a goodly number of scientists. There is also reason to believe that not a few mining professors and experts are inclined to accept the view, but it is not openly acknowledged because of the fear of being regarded as faddists by their constituents.

Admittedly the solution of this problem presents many difficulties to the ordinary man, and as colliery people have a way of regarding themselves as eminently practical, "new fangled notions" are looked upon by them with a certain amount of suspicion. There was abundant evidence of this when the coal-dust theory was propounded. Discussion raged furiously and there were not a few departures from friendly relationships. It is interesting to recall that this was less than four decades ago and today the man who doubts the theory is looked upon as old-fashioned and behind the times. Can it be that history may repeat itself in regard to the seismic theory?

There certainly seems to be a fairly general agreement that atmospheric changes and local emissions of gas from the mines have a close relationship, and in Great Britain, barometrical fluctuations are carefully recorded, warnings being periodically issued to mining communities when the conditions presage special danger from outbursts of gas. Beyond this it may be advanced that the theory holding the spasmodic or irregular earth breathings responsible to some extent for explosive conditions in mines, may not after all be wholly unreasonable.

Mine Inspectors Instituted Inquiries

Mention may be made of the fact that eight years ago the British inspectors of mines instituted inquiries—unfortunately neither uniform nor conclusive—to ascertain whether earth tremors had any tangible effect upon falls of roof in mines. They appear to have taken this course because, notwithstanding the adoption of new special rules to secure systematic timbering, falls of roof and side continued to be as fruitful a source of accident as in the pre-systematic days. Indeed this remark, after the lapse of a number of years, may still be held to apply.

So far as they go the results secured by the mine inspectors may be summarized: W. N. Atkinson selected a period of two months in the year 1902 and observed that 33 earthquakes were registered at the Kew Observatory. Mark-

ing upon a large chart the exact times of 156 accidents from falls in six inspection districts, he says he relinquished his inquiries because "there did not appear to be the slightest indication to coincide, between the times of the earthquakes and those of the accidents."

A diagram was prepared by A. H. Stokes which seemed to indicate that the winter months was the period of the year in which most accidents from falls occur, but he could not convince himself that climatic changes have a material influence upon the death rate therefrom. He was inclined more to the view that the increased time worked in the winter period was responsible for the increased death rate.

Not satisfied with that evidence, John Gerrard sustained the earth-tremors theory, and Henry Hall was severe upon the mine management in the statement of his conclusion that "we suffer from the fact that no very direct responsibility in these cases rests upon any individual officer."

That it was quite possible seismic movement of the earth's crust might be a deep seated and unsuspected cause of many accidents from falls, was admitted by W. H. Pickering. As he remarked, earth tremors, reaching the dignity of earthquakes, pass at times across the British Isles—but hitherto they have never been considered to be a factor in mining accidents.

London, England. S. T. A.

Vertical Curves to Prevent Derailment

Your readers may be interested in a method of calculating vertical curves that is better known to municipal engineers than to those who follow their profession in the mining fields. Curves of this kind are useful in preventing derailments and save a lot of grading by trial and error, which is too common where a true curve is not predetermined. To make a clear illustration, a somewhat extreme case is taken.

The plane to be built is 520 ft. long. The lower end has a 2 per cent. grade, the upper a 50 per cent. The plane starts at station 0 and the point of intersection of the two grades is 3 The profile drawn has vertical scale $2\frac{1}{2}$ times as large as the horizontal, resulting in a vertical distortion of $2\frac{1}{2}$. The elevations, above tide, of the subgrades at the ends of the plane and at the point of intersection are marked, as is customary, with small flags; the heights of the subgrades, that is, the elevations at which the ties are to be placed, as a result of calculation, are marked on the profile, in the appropriate places, without the use of flags.

To shorten the solution it will be assumed that a break in grade is made every 100 ft., though it would be well to make the break at intervals of 25 ft. The principle is the same. The point of vertical curve (*P. V. C.*) is chosen at a distance 200 ft. from the point of vertical intersection (*P. V. I.*), that is, at station 1. So the projected length of the curve will be 400 ft., the point of vertical tangent (*P. V. T.*) being at station 5.

Gradient at *P. V. C.* is 2 per cent., or 2 ft. per station.

Gradient at *P. V. T.* is 50 per cent., or 50 ft. per station.

The difference is $d = 48$ ft. per station.

The number of stations covered by curve is $n = 4$.

We obtain a value x from the equation

$$x = \frac{d}{2n} = \frac{48}{8} = 6.$$

Subgrade at *P. V. C.* = (Subgrade at Sta. 0) + 2 = 1107.9 + 2 = 1109.9.

Gradient at *P. V. T.* is $\frac{50 \times 25}{100} = 12.5$ ft. per station.

Algebraic difference (d) is 12 ft. per station.

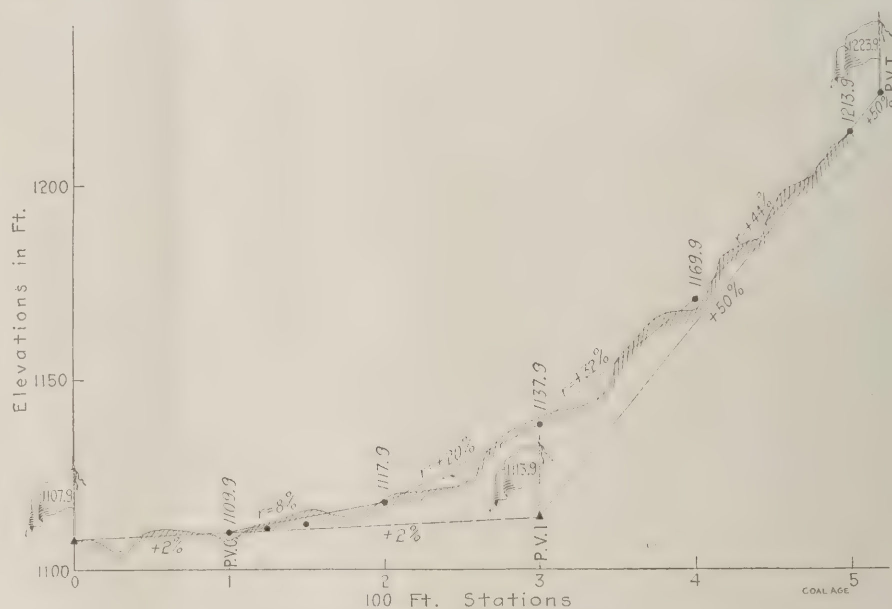
The number of stations covered by curve is 16.

We find, therefore, that

$$x = \frac{d}{2n} = \frac{12}{32} = 0.375.$$

The calculation is too long to complete, but commences thus:

$r = 0.5$	
$x = 0.375$	Elev. 1 + 00 = 1109.900
$r = 0.875$	$r =$ 0.875
$2x = 0.750$	Elev. 1 + 25 = 1110.775
$r = 1.625$	$r =$ 1.625
	Elev. 1 + 50 = 1112.400



A Vertical Curve on a Steep Plane

Proceed as follows, making rise per station $= r$.

$r = 2$	
$x = 6$	Elev. Sta. 1 = 1109.9
$r = 8$	$r =$ 8.0
$2x = 12$	Elev. Sta. 2 = 1117.9
$r = 20$	$r =$ 20.0
$2x = 12$	Elev. Sta. 3 = 1137.9
$r = 32$	$r =$ 32.0
$2x = 12$	Elev. Sta. 4 = 1169.9
$r = 44$	$r =$ 44.0
$x = 6$	Elev. Sta. 5 = 1213.9 Check.
$r = 50$. Check.	

This, it will be observed, is exactly the figure given for the *P. V. T.* If the length of the adopted distance between the breaks of grade is 25 ft. instead of 100:

Gradient at *P. V. C.* is $\frac{2 \times 25}{100} = 0.5$ ft. per station.

It will be observed that the first increase of grade is half the second, just as the first chord in a circular curve makes with the tangent an angle half that which it makes with its neighboring chord.

Such a curve will make derailments unlikely. Where rapid changes of grade take place vertical curves should always be inserted. In return car sidings where empty cars run continually into standing trips, it would be well to figure out vertical curves and to model the grade carefully from the beginning, instead of leaving the matter to adjustment by trial and error. It must be remembered that d is the algebraic difference; if one gradient is up hill and the other down hill, d is the sum of the two gradients per station. By taking only two stations, the apex distance can be easily determined. In this example the stations would be 200 ft. long and d would equal 96; $n = 2$, and $x = 24$. The elevation of the curve at the apex would be 1137.9, as already determined for the same curve with 100-ft. stations.

Sociological Department

For the Betterment of Living Conditions in Mining Communities

First Aid Methods of Lackawanna Company

By C. E. Tobey*

There was a time—not many years ago, either—when the poor injured miner was dragged out of the mines by willing, but rough hands; his injured parts were crudely wrapped up with a dirty handkerchief or any old piece of cloth available, such as a discarded pair of overalls or working pants, and if there were any open cuts or bruises, these were frequently smeared over with fresh quids of chewing tobacco. For in those days chewing tobacco was supposed to have a wonderfully healing effect, regardless of the mouth from which it was extracted. If any of these cuts severed an artery, the man frequently bled to death before a doctor could be procured to stop the flow of his life's blood.

No special care was taken to splint or support a fractured limb so as to prevent further injury, for the average man knew nothing about the danger of fractured bones piercing through the flesh, or how to prevent such an undesirable result.

Trained First-aid Men of the D. L. & W. Mining Department

The injured man was carried to his home, sometimes thrown over the shoulder of some strong, robust helper; sometimes two of his fellow workmen would carry him by the head and heels. If there was a saloon on the way it was necessary to stop long enough to drown the poor fellow's pain with rot-gut whiskey, and, incidentally, to furnish, in the same manner, more strength for those carrying him. If the patient survived this kind of treatment and was alive when they got him home, it was a question whether he even then got proper surgical and medical attention, as doctors were not as plentiful as they are now and they cost money, and the chances are that some quack heal-all or bone-setter would get hold of the patient and finish him.

D. L. & W. R.R. Rescue Corps

Those days are past. Each and every one of the D. L. & W. mines has one or more First Aid Corps, composed of six or eight bright, energetic young men thoroughly drilled and instructed by the best of surgeons in the proper manner of rendering first aid in all kinds of fractures, cuts, bruises, shocks, etc.

These men are equipped with all the necessary paraphernalia to give prompt assistance in time of injury. They have stretchers, splints and blankets, as well as a box containing antiseptic gauzes and bandages, and when a man is injured, word is immediately sent to one or more of these men, and they get to the scene of the accident with all possible haste, and assume charge of the injured. They first make him as comfortable as possible, and then locate the injury. If it should be a broken leg, they immediately rip open the trouser leg to see that no bones are protruding. The fracture is reduced, if possible, and the leg supported and bandaged so as to prevent any further injury in moving the patient.

A Frame for an Injured Leg

We have for this purpose in our mine hospitals a frame made of light rod iron, passing down each side of the leg and around the foot, and when the leg is securely bandaged in this frame you could safely throw the patient out of the window without the least possible danger of further injuring that leg. It is not absolutely necessary, however, to have these regular frames, or to delay the work until something of the sort can be procured, as the meaning of "First Aid" is the assistance of the patient and the making of him comfortable with such means as are available until such time as a regular surgeon can be reached, and even a pick or sledge handle can be made to answer the purpose of splint or sup-

*Superintendent coal department, D., L. & W. R.R.

Note—Address delivered at Penn. State Y. M. C. A. Convention, Bradford, Penn., on Feb. 23, 1912.

port, providing it is properly secured by bandages to the limb. Neither is it necessary to await the arrival of a regular stretcher, as a very comfortable appliance can be improvised quickly by placing two rods or sticks through the sleeves of two or three coats or jumpers.

If there should be any open cuts or wounds to contend with, our First Aid boys are fully alive to the dangers of infection and blood poisoning from the many germs lurking on their dirty hands and clothes. As the Irishman explained to his friend: "Pat, did you ever know that the doctors now claim that all diseases and sickness are caused by a 'bug'? If yez cut off yer thumb and die of lock-jaw, it was a 'bug' that done it. If yez catch cold on yer lungs and ye're carried off by consumption, it was a 'bug' that done it. If yez get hay-fever, it's a 'bug', and if yez has the grippe its another 'bug.' In Germany they call these 'bugs' 'Germs.' In France they be called 'Parisites,' and in Ireland they do call 'em 'Mikerobes'."

Our men are careful not to touch these cuts or wounds with their hands or dirty clothes, but they use antiseptic gauze, taken from their sealed packets. If an artery has been severed, our men know how and where to place the tourniquet so as to stop the flow of blood and thereby save the man's life. No liquor is given the patient, but if any stimulant is needed, a little aromatic spirits of ammonia is given in water.

Artificial Respiration for Five Long Hours

If the man has been completely "knocked out" and has the appearance of being dead, as is frequently the case in shocks or after-damp, his heart may continue to beat for several minutes after he stops breathing. Artificial respiration is then the only way of restoring life, and when properly done and persisted in, will force the man to breathe whether he wants to or not. We had a case of this kind in one of our mines when artificial respiration was kept up for three-quarters of an hour, and the patient is working for us today. Everybody but our superintendent pronounced the man dead, but he would not give up; nor would he allow the others to quit. We had another case in our company hospital where artificial respiration was continuously kept up for five hours, and the patient is still living to tell the story.

After the injuries have all been properly dressed and protected from dirt and contamination, the patient is placed on a stretcher, carefully covered with blankets so as not to get chilled, and hoisted to the surface without any unnecessary jars or jolts.

Iron Frame for Injured Leg

The ambulance has already been prepared and is in waiting, and the injured man is conveyed on a mattress to the Moses Taylor Hospital, which is in charge of one of the most skillful and capable surgeons in this country. There the patient is left under the watchful eye of a trained nurse, and is not allowed to leave the hospital until all danger is past.

The Hospital Car at Kingston, Penn.

The Interior of the Kingston Car

The Hospital Car

In our Wilkes Barre district, where the mines are located some 16 or 20 miles distant from the company hospital, we have a regularly equipped hospital car standing at Kingston Station under heat, and ready at a moment's notice to convey injured employees to the Scranton hospital.

If a regular passenger train is due at the time, this car is attached to that train, but if between trains, and the condition of the injured will not warrant delay, a switching engine is immediately attached and the car hurried to Scranton as a special. This car has cots and blankets and everything necessary to the comfort of the injured while being transported, and, if the conditions warrant it, the company surgeon located at Kingston, accompanies the patient to Scranton, and has been known to successfully reduce fractures and perform amputations and other operations while *en route*.

In conjunction with this hospital car we also have a rescue car fully equipped with helmets and rescue appliances, oxygen, etc., and at most of our important mines we have rescue stations similarly equipped and manned by employees thoroughly drilled in the use of these helmets and pulmotors. These men have been confined in sealed rooms filled with sulphur fumes and required to saw timber, shovel coal and dirt, crawl through low places, carry stretchers over obstructions, etc., while wearing these helmets, and they all have the necessary strength and nerve to enter a burning mine and rescue the men. This car was rushed to the scene of the terrible Pancoast disaster last spring, but, unfortunately, did not get there in time to save any of the 73 unfortunates who lost their lives.

We also have another car located at Kingston fully equipped with all kinds of fire fighting appliances, and, in case of a bad accident or big mine disaster, this special train, consisting of rescue car, fire car and hospital car, is immediately dispatched to the scene.

Inquiries of General Interest

All Questions Must be Accompanied by Name and Address—Not for Publication

Handling a Mine Fire in a Gassy Mine

Referring to the accompanying sketch, which shows a fire started at the face of the intake gangway in a mine, what would be the best method of fighting this fire so as to insure the greatest amount of safety to the men? As shown in the sketch, there are eight chambers driven to the rise of the gangway. In six of these chambers there is gas given off at the face. The direction of the air current is shown by the arrows and it will be noticed that the gas given off at the face of the chambers is being carried toward the fire. This question has caused considerable warm argument here and developed a great diversity of opinion among practical mining men.

ROBERT WILLIAMS.

Wilkes-Barre, Penn.

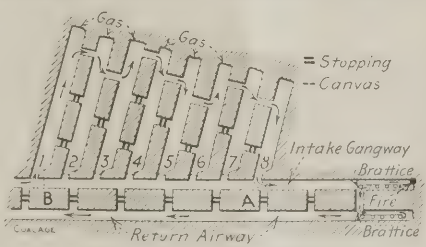
The first consideration, after withdrawing all men from the mine, is to keep the gas from the fire and to accomplish this before anything else is done the stopping at *A* should be partly opened. This would short-circuit the air at this point, and the gas being generated at the face of the chambers will be conducted directly into the return airway.

Since there has been, as yet, no explosion of the gas contained in the air current passing over the fire, it may be assumed to be safe to allow this air to circulate past the fire for the present and not to short-circuit the whole of the air current. For this reason the stopping at *A* should be opened only sufficiently, at first, to reduce the quantity of air passing the fire. Reducing thus the quantity of air will, to some extent, dampen the fire.

The next step is to arrange so as to carry all of the gas-laden air coming from the chambers, through the crosscut at *A*. This, however, cannot be done with safety until a portion of the intake current entering chamber No. 1 can be conducted through the canvas at *B* and along the gangway to the fire, so as to dilute the gases formed by the fire, which will rapidly become explosive when the current is reduced. This current will be fresh air containing no gas and will eventually replace the air from the chambers containing gas which is now feeding the fire.

In order to accomplish this it will be necessary to construct a box of sufficient size to conduct the air from the chambers across the gangway to the crosscut at *A* through which it passes into the return airway. This box can be constructed quickly by nailing canvas to suitable crossbars in the gangway. This box will form a sort of air bridge, at the roof of the gangway, and is represented by the dotted line drawn from the mouth of chamber No. 8 to the crosscut *A*. Before constructing this box or air bridge it will be best to open the canvas at *B* sufficiently to divert a portion of the air passing up the chambers, into the gangway. How much this current can be reduced in the chambers should be determined by a fireboss, who must watch the gas at the face of the chambers, and especially the condition of the current in chamber No. 8.

As soon as the air bridge at crosscut *A* is completed the air reaching the fire will



SHOWING LOCATION OF FIRE AND DIRECTION OF AIR CURRENT

be practically fresh air containing little or no gas. This current, however, should be only sufficient to allow men to approach close enough to the fire to extinguish the flame, and to avoid the possible formation of an accumulation of explosive gases (carbon monoxide), in the region of the fire.

All of the work should be done with safety lamps and every precaution should be used to protect all approaches to the return airway and prevent anyone from entering the return current. In the meantime, arrangements will have been made to conduct water to the fire.

Ventilating Pressures

If the water-gage reading taken on the fan drift is 2.2 in.; (*a*) What is the unit of ventilating pressure? (b) What is the mine resistance indicated by this reading if the fan drift, at this point, is 12 ft. wide and 10 ft. high? (c) What is the absolute pressure on the mine air at an elevation of 1000 ft. above sea level?

Fairmont, W. Va. J. B. W.

The unit of ventilating pressure is

$p = 5.2 \times 2.2 = 11.44$ *lb. per sq.ft.*

(b) The area of the fan drift is $10 \times 12 = 120$ sq.ft.; and the mine resistance is then

$R = pa = 11.44 \times 120 = 1372.8$ *lb.*

(*c*) The atmospheric pressure, at an elevation of 1000 ft., is 2041.1 lb. per sq.ft., and the unit of ventilating pressure being 11.44 lb. per sq.ft., the absolute pressure is $2041.1 + 11.44 = 2052.54$ lb. per sq.ft.

Pumping into Tank

We expect to pump water into a large tank 25 ft. above the ground. Would it be better to run the discharge line or column pipe to the top of the tank where it would have a free discharge, or to enter the pipe at the bottom of the tank? What would be the advantage in either case?

Dubois, Penn. MINE FOREMAN.

Although, by far, the most common practice is to enter the column pipe and terminate it at the bottom of the tank, this is not the absolute rule, as there are numerous advocates of extending the pipe up the outside and allowing it to discharge into the tank at the top.

Entering the pipe at the bottom reduces the head under which the pump must work when the tank is not full. There is a less length of column pipe to protect from freezing and a corresponding decrease in frictional resistance in pumping. The resistance to discharge at the end of the column pipe is practically the same in either case, whether the pipe discharges into the body of water in the tank or against the atmosphere at the top of the tank.

Pumping in Shaft

The column pipe in a shaft 200 ft. deep is 16 in. in diameter; and all the pumps are arranged to discharge into it. When not required, all the pumps are stopped but one, which has a 2-in. discharge. Would it be better if this pump had its own discharge or column pipe to the surface or will the pump do as well when discharging into the large 16-in. pipe?

MINE SUPERINTENDENT.

Pittsburg, Penn.

It is often the case that pumps arranged to discharge into the same column pipe do not work satisfactorily, when operated together. The fault is due generally to improper design. In the case in hand, the single pump having a 2-in. discharge will work as well or better when discharging alone into the large 16-in. pipe. The pipe friction will be less, for the same flow, than in a pipe of smaller diameter.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Questions Asked at Fireboss Examination, Held at Cumberland, Wyo., Jan. 29-31, 1912

(Continued from March 9)

Ques.—What are the dangers attending windy shots and how would you guard against them?

Ans.—A windy shot always produces a large disturbance of the mine air; and, in case dust is present in considerable quantity in the working place, a cloud of dust is raised and a local dust explosion may be produced, the fine dust floating in the air being ignited by the flame of the shot. If, as is often the case, gas has accumulated in the space over the waste or gob, this gas will be ignited and a local explosion produced. A windy shot often loosens the roof at the working face. Where safety lamps are used, the concussion of the air may force the flame of the lamp through the gauze and ignite the gas. The best way to guard against these dangers is to avoid producing a windy shot.

The following precautions are suggested: Avoid an overcharge of powder; drilling the holes too deep on the solid; drilling a "dead hole," by which is meant a hole perpendicular to the face of the coal. Such a hole has no opportunity to work, unless a suitable mining or side cut is made extending nearly or quite to the depth of the hole. Avoid locating a charge too close to a hard roof or near to a boulder. Cut away all projecting tops and bottoms that would prevent the shot from doing its proper work. Avoid firing two or more shots in quick succession in a close place. Never place one shot dependent on the work of a previous shot and fire these two shots at the same time expecting one of them to explode first, the work of the second depending upon that of the first. Where gas is generated always test the face of the chamber for gas before firing a shot. Avoid all accumulation of fine dust and coal, at the working face.

Ques.—What is meant by splitting the air current and what are the advantages of so doing, if any?

Ans.—By splitting is meant dividing the air current into two or more separate currents, each of which will ventilate its own section of the mine from the moment it leaves the main intake until it reaches the main return. By this means the ventilation of the mine is under better control, since the air current can be divided in proportion to the requirements in each section of the mine. Better ventilation is afforded at the working face, since the air is fresher, contains less gas, smoke and dust and travels at a more moderate velocity. Any explosion of gas occurring in one section of the mine is generally confined to that section. A larger quantity of air is circulated by the same power; or for the same quantity of air required the power producing the circulation is reduced. Splitting the air current in a mine reduces the number of doors required, but generally requires the use of regulators and the construction of air-bridges.

Ques.—How would you proceed to clear a shaft that is filled nearly to the top with carbon dioxide, without the use of a fan?

Ans.—In a deep shaft the removal of the blackdamp might prove a difficult operation and in most cases a fan would be needed for that purpose. Assuming, however, a shallow shaft and barring the use of a fan, recourse must be had to such simple methods as the emptying of several barrels of water into the shaft, in quick succession; the use of large bailing buckets lowered and hoisted rapidly; the use of a steam jet or blower at or near the bottom of the shaft. If there is a partition or manway extending down one side of the shaft, advantage can often be taken of the wind pressure by erecting a canvas or cowl, so as to deflect the surface wind into the shaft. It will, however, generally be difficult to remove a large volume of blackdamp from the shaft without the use of a fan, the employment of which would save much time and expense.

Ques.—How would you remove an accumulation of gas from a mine, with safety?

Ans.—Everything will depend on the character of the gas, its location in the mine and the strength of the air current. Assuming, however, a body of marsh gas (CH_4) accumulated at the head of a steep pitch, which is the probable meaning of the question: First, notify the men on the return of the air current and, if the body of gas is large, withdraw all the men from the mine before attempting its removal. Having done this and having stationed reliable men at all points necessary to protect the return airway and prevent persons from entering the same, increase the quantity of air passing in the affected portion of the mine, as much as possible. Then, having brought the air in sufficient volume to the foot of the pitch and having the necessary material at hand, proceed to erect a temporary brattice, to conduct the air current up one side of the chamber, allowing it to return down the pitch, on the other side of the brattice. Only safety lamps must be used and the work must all be done on the intake side of the brattice. Sufficient time must be allowed for the air current to sweep away the gas each time that the brattice is extended; the work is necessarily slow. All lamps should be kept at a safe distance back from the ends of the brattice. In this manner, the work should be extended up the pitch until the face is reached and the gas removed.

Ques.—If you were about to examine a mine for explosive gas, what would you consider your first duty as a fireboss before you entered on your rounds through the mine?

Ans.—Having filled and properly cleaned his safety lamp, the fireboss, before entering the mine, should ascertain that the ventilator is running at its usual speed. After lighting and carefully inspecting his lamp, on entering the mine, he should proceed at once to the foot of the downcast shaft, or to the nearest point accessible on the main intake airway; and, here, before proceeding further on his rounds, he should assure himself that the usual quantity of air is passing in the airway. In a very gassy mine or where the mining laws or mine regulations require, the fireboss should place a suitable danger signal at the mine entrance, which will remain there as a warning to all persons not to enter until he has returned from his examination and removed the signal. Before examining a gassy mine it is well, if the fireboss is able to do so, to make a special test of his lamp before entering the mine.

Ques.—If it is found necessary to increase the quantity of air in a mine, how would you do it without increasing the speed of the fan?

Ans.—Remove all obstructions from airways; clean up any roof falls; enlarge all breakthroughs or crosscuts and straighten the airways and shorten the distance the air must travel wherever this is practicable. Split the air current whenever this can be done to advantage or without reducing the velocity of the air current to a point too low to sweep away the gases and provide good ventilation at the working face.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

Strong interest is felt in government circles with reference to the British coal strike and its reflex effects upon our own coal trade. The immediate influence of the strike, as observed here thus far, has been the stimulation of export business. While full figures are not yet available at the statistical offices, it is known that large quantities of coal are being loaded at Atlantic ports for South American and European points which are usually supplied from English mines.

Should it prove possible to avert a coal strike on this side of the water it is believed that a large, and possibly permanent, gain in our foreign business will be secured. This makes it doubly desirable, according to the views entertained here, that there shall be no violent disturbance of existing conditions in our coal industry. Government officials incline to the opinion that, in view of the circumstances, the operators can afford to make some concessions in order to secure for themselves a valuable opportunity to expand their business in this new direction.

It is well understood here, of course, that the bituminous mines of the country have not been in a money-making position for some time, and this fact has been brought out repeatedly during the past few weeks, not only by statements before the Interstate Commerce Commission in connection with pending coal cases, but also in arguments before committees of Congress in connection with various bills under consideration.

Reports received in Washington, are to the effect that a month's supply of coal is already in sight at different points, and that heavy outputs will be maintained from now until the end of the current month, when prevailing wage agreements expire.

Altogether, the coal situation is regarded here with considerable anxiety and a good deal of attention is being paid to it in Congress. While it is believed that an agreement will be reached on some basis through the submission of modified demands by either side, there is not a little anxiety lest some serious dispute should be precipitated. Should difficulties of an acute nature arise, the national government, it is felt here, would almost necessarily intervene, perhaps along the same lines that were followed under the Roosevelt administration, for the purpose of effecting an adjustment. Such plans are, of course, purely tentative, but the fact that they are being talked of with seriousness is considered decidedly significant.

Provision for Government Coal Business

A specially interesting feature of the new Panama Canal bill, so far as the coal trade is concerned, is that portion which is intended to give the President power to sell coal and other supplies to passing vessels. This provision is found in Section 6 of the bill and reads as follows:

> The President is also authorized to establish, maintain, and operate drydocks, repair shops, yards, docks, wharves, warehouses, storehouses, and other necessary facilities and appurtenances for the purpose of providing coal and other materials, labor, repairs and supplies for its own vessels, and, incidentally, for supplying such at reasonable prices to passing vessels, in accordance with appropriations hereby authorized to be made from time to time by Congress as a part of the maintenance and operation of the said canal.
>
> Moneys received in the ordinary course of business from the conduct of said business may be expended and reinvested for such purposes without being covered into the Treasury of the United States; and such moneys are hereby appropriated for such purposes, but all deposits of such funds shall be subject to the provisions of existing law relating to the deposit of other public funds of the United States, and any net profits accruing from such business shall annually be covered into the Treasury of the United States. Monthly reports of such receipts and expenditures shall be made to the President by the persons in charge, and annual reports shall be made to the Congress.

Alabama

Birmingham—The Corona Coal & Iron Co., which L. B. Musgrove and associates have been operating for some years, was recently purchased by Edgar L. Adler of Birmingham, the price paid for the corporation and its physical holdings being approximately $1,000,000. The property includes about 45,000 acres of the Corona seam, which is a high grade domestic coal. The new owner expects to spend about $250,000 in betterments to the present equipment and for new openings, in an effort to produce 1,000,000 tons of coal annually. Heretofore about 500,000 tons have been obtained each year. The plants now in operation include the Corona, Coal Valley and Patten mines.

The bee-hive coke ovens of the Tennessee Coal, Iron & R.R. Co. at Bessemer and at Alice Furnace, Birmingham, have been put out of commission by the firing of the first battery of the company's new Koppers byproduct ovens at Corey. Other bee-hive ovens will be shut down as the balance of the new plant is finished, during the next few months.

Colorado

Meeker—A contract has been awarded for the immediate construction of a railroad from Rifle to Harvey Gap, which will tap the coal beds at the latter point. This line is being built by the Garfield Coal Co. and will open up deposits of coal that are among the largest in the state.

Denver—By an agreement entered into, Mar. 5, between officials of District No. 15, United Mine Workers of America, and the American Fuel Co., the strike in the Northern coal fields, which has been in progress for nearly two years, is virtually settled so far as the eight mines of this company are concerned. As a result, about 300 men have returned to work in Louisville and Lafayette and it is reported that nearly 1000 will return to work in the Northern field before long. Under the agreement, the men are given an increase of 3c. a ton on the run-of-mine coal and of 5 per cent. on day work. They asked for an increase of 5.55 per cent. on all work.

Fort Collins—The proposed development of a coal mine at Fort Collins has fallen through for lack of funds needed to purchase the property. Outside capital refused to invest in the company and it was compelled to relinquish its holdings.

Illinois

Chicago—Announcement was made recently that the Chicago & Eastern Illinois R.R. had purchased approximately 28,000 acres of coal land in Montgomery County, Illinois, for $2,500,000. This is regarded as the largest coal-land deal negotiated in Illinois for a number of years. The property was sold by A. R. Bird & Sons of St. Louis and the transfer was handled by the banking firm of Kuhn, Loeb & Co. of New York. The new acquisition increases the coal-land holdings of the Chicago and Eastern Illinois road to 38,000 acres. The purchase represents five mines. The railroad, however, will not operate these but will continue the present leases for a number of years. The property was acquired in order to in-

sure and safeguard the railroad's fuel supply, according to a statement made by the president of the company.

Representatives of the coal operators of western Pennsylvania, Ohio, Indiana and Illinois met with representatives of the United Mine Workers in Chicago, Mar. 5, and arranged for a conference of the joint scale committee to take place in Cleveland Mar. 20. Briefly, the demands of the miners are that the present working day of eight hours be decreased to seven hours, with five hours on Saturday at full pay, and a 10 per cent increase of the present wage scale.

Duquoin—The Chicago and Carbondale coal mine, at Ward has been taken over by the Mississippi Valley Mining Co. for a consideration of $75,000 and is now in operation. The town of Ward was almost depopulated on account of this mine not working during the past year. The mine had filled with water and was generally run down but the work of reclaiming has been going on rapidly and it is expected that an output of 500 tons a day will soon be attained.

Centralia—The Junction City mine of the Marion County Coal Co. recently broke its own record by attaining a production of 1800 tons in one day. The mine employs 375 men.

Streator—The Chicago, Williamson and Vermillion Coal Co. is putting down a number of bore holes northeast of here in hopes of locating a bed of coal that will justify opening a new mine. This company's present No. 3 mine, near here, will probably be worked out during the year.

Indiana

Logansport—In order to be prepared for a possible strike of the coal miners of the country, an official of the Wabash railroad recently made arrangements to store here a large quantity of coal for the railroad's use. The Wabash intends to store coal all along the different divisions and at all its terminals.

Terre Haute—Miners are in great demand in this vicinity, some coal companies advertising that they require as many as 80 additional men. A strike or suspension on Apr. 1 is regarded as inevitable and every effort is being made to get out as much coal as possible before that date.

Princeton—The Princeton Coal Company's mine, here, has been sold to the Deep Vein Coal Co., of Terre Haute.

Brazil—The Clay County board of mine examiners has secured an opinion from Attorney-General Honan, holding that the examining boards established by the last general assembly cannot legally issue certificates to mine workers except at the regular meetings of the board. In regard to apprentices, Mr. Honan holds that an apprentice must work under a qualified miner for two years and cannot legally be employed elsewhere in preparation for a certificate.

Indiana coal operators have sent a petition to the Indiana railway commission asking for secrecy regarding their daily reports to the commission which give the number of cars received and loaded, and the number of hours of work at each mine. The order requiring the reports to be made provides that they shall be made public property. The operators say that under the order, coal brokers are enabled to keep in touch with conditions at the mines, and, on that knowledge, often take advantage of shortages in cars or shutdowns to interfere with the sale of coal by the operators.

Iowa

Des Moines—A recent strike at the Ray coal mine southwest of here, originating in differences with regard to the double work system employed at the mine, was soon settled by an amicable agreement. It is said that there is not an idle miner in the Iowa fields at this time, unless it is because of accident or other special reason. The maximum amount of coal is being mined daily in order to store away as much fuel as possible. Operators estimate that in case the miners suspend work Apr. 1, there will not be enough coal stored away to last more than a month or six weeks.

Kentucky

Louisville—Information from Pikeville is to the effect that Congressman John W. Langley, of the tenth Kentucky district, and Congressman James A. Hughes, of the fifth West Virginia district, will wage a vigorous fight to secure appropriations of $50,000 each for dams on the Levisa and Tug forks of the Big Sandy River, in the annual rivers appropriation bill of Congress. The War Department, after assisting last year in securing the insertion in the rivers bill of authority for the building of these two dams has now concluded that a resurvey should be made before the projects are pushed to completion. These dams will be of inestimable value to the coal industry in western West Virginia and eastern Kentucky, and a delay of one, two or three years would be a serious matter to mining interests. Messrs. Langley and Hughes, in discussing before the House committee the need of appropriations for these two dams, pointed out that they would be of considerable value in demonstrating the importance of the further development of such projects along the Big Sandy.

Whitesburg—It is believed that a number of new towns will spring up this year in the vicinity of Whitesburg, as a result of the expenditure of millions of dollars in development work by the Consolidation Coal Co. and other concerns now active in this field. The Consolidation company has announced that it, alone, will spend $4,000,000 in development work. Jenkins will have 8000 population by Sept. 1, it is estimated. McRoberts, on Wright's Fork, is growing rapidly, and another town is planned for a point farther down on Boone Creek. Dunham and Burdine are growing fast and the Mineral Development Co., a Philadelphia concern, contemplates building a model mining town along Moore's branch, on a large area owned by the company.

Ohio

New Salem—Fire, Mar. 2, destroyed the large wooden tipple of the Buck Coal Co., just east of here. No water was available for fighting the flames but the fire did not spread from the tipple to surrounding buildings. The mine had been shut down for some time.

Alliance—Subdistricts 4 and 5 of District No. 6, United Mine Workers, held their convention here recently and elected officers but refused to discuss the probabilities of a strike, prior to the conference of higher authorities.

Columbus—The hearing before the Federal Court in Columbus of the suit brought by the Federal Government to compel the dissolution of interests alleged to exist between certain railroads and coal companies was brought to a close recently. During the hearing, several prominent coal men were on the witness stand. In summing up for the prosecution, the representatives of the government claimed that in spite of the defendants' pretense of complying with the antitrust laws, the competition which existed in the Hocking Valley coal fields previous to 1899, at which time the combination was formed, has never been restored. The government claims that this combination is still in force under cover, and that there has been at attempt to conceal the fact by a juggling of professed ownership among the various units of the big syndicate.

Oklahoma

McAlester—The 445,000 acres of segregated coal and asphalt lands of the Choctaw and Chickasaw nations will be sold to the highest bidders as soon as the departmental regulations can be put into effect and a land office opened in this city.

Pennsylvania

Bituminous

Brownsville—After a strike, lasting about 10 days, which threatened to involve the Crescent and Vigilant mines, the miners at the Chamouni works of the Monongahela River Consolidated Coal & Coke Co. have made a compromise agree-

ment, lasting until Apr. 1, and have returned to work. About 200 men went out on strike as a protest against the use of safety lamps.

McDonald—About 500 men, employed at the Jumbo mine of the Pittsburg Coal Co., went on strike recently, as the result of an order compelling the machine men to use safety lamps. It was reported that the miners at the company's Champion mine, at Sturgeon, would strike also.

Indiana—A large field of coal is now being optioned in the heart of the coal-producing section of Indiana County. There are no openings in the immediate vicinity. Options have been taken a number of times on this field, but for different reasons the deals were never consummated. The field in question separates large holdings, now owned by the Buffalo & Susquehanna Coal Co. and the Rochester & Pittsburg Coal & Iron Co.

Connellsville—Coke production has materially increased during the past week, and a number of idle plants are being put in shape to start up on short notice. Much new business is expected to come this way in the event of a coal strike.

Uniontown—The McKeefry plant has resumed coking operations, after a year's shutdown.

Scottdale—The Shannon Coke Co., which has been idle for over a year, recently resumed operations by firing 42 ovens.

Fayette City—The Pittsburg & Lake Erie R.R. Co. and the Pittsburg Coal Co. are having a dispute over a right-of-way claimed by the railroad over property owned by the coal company. Recently tracks were laid over the ground of the coal company and later, employees of the coal company removed them. To prevent further work on the part of the railroad, the coal company laid a steam line to the ground in dispute and fitted it out so that a shower of steam can be turned on any invaders.

West Newton—Five hundred and fifty-three acres of Pittsburg-seam coal, in Cross Creek Township, Washington County, were recently sold to Pittsburg interests for $100 an acre. The purchasing company has already begun the erection of a tipple and installation of machinery.

Pittsburg—Rapid progress is being made on the extension of the Monongahela railroad, being built out of Martin, Penn., and running southward to the Pennsylvania and West Virginia state line. It will be operated by the Pennsylvania and the Pittsburg & Lake Erie railroads and will also connect with the Buckhannon & Northern. The road will open up valuable coal lands in Greene County, Penn., and for this reason the New York Central system has been trying to obtain an entrance into the territory for some years. Forty-five miles of road are now under construction. It is expected that the work will be completed by June.

Anthracite

Scranton—The Delaware, Lackawanna & Western company recently became the owner of the Isaac Felts coal lands, in Taylor, some 120 acres in extent and said to contain several millions of tons of coal. The tract will be worked by the Lackawanna company from its Holden mine.

Although only a month has passed since the breaker of the Connell Anthracite Mining Co., at Bernice, burned to the ground, a temporary structure has been erected in its place, capable of turning out 1250 tons of coal daily.

Members of the district executive board of the United Mine Workers announce that active steps are being taken to build up the ranks of the union throughout the anthracite region. Fifteen national organizers have been ordered into Pennsylvania to round up into the union every man now employed.

Wilkes-Barre—The boiler house of Lance, No. 11, colliery, at Plymouth, was recently destroyed by fire. The breaker and adjoining buildings were in some danger but escaped injury.

Five houses were seriously damaged by a subsidence of the surface over old mine workings, at Plains, near here, Mar. 5, due to an extensive cave-in in old workings of a Delaware & Hudson mine.

Conservative estimates have it that fully 2000 foreigners have already departed from the anthracite region. These men are laborers in most instances, but a number of experienced miners also have started back home.

Pittston—Traffic on the Lehigh Valley cut-off was delayed several hours, Mar. 4, by a cave-in under the tracks at a point near the Butler breaker.

Utah

Salt Lake City—The National Fuel Co. has been organized with $1,000,000 capital to develop coal deposits in Carbon County. The company has taken over 1000 acres of land, 14 miles west of Helper, Utah, and announces its purpose of constructing a railroad from this tract to Helper, to connect with the Denver and Rio Grande. It is the intention to begin construction this summer.

The American Fuel Co., of Utah, which owns 1000 acres of coal land in Grand County, recently sold $50,000 worth of stock, and the money accruing from this sale together with that from other sales in process of consummation will be devoted to the construction of a railroad, 5 miles in length, which will connect the company's mines with the main line of the Denver & Rio Grande at Thompsons.

Washington

Palouse—Organization of the Palouse Coal & Oil Co., started last November, was completed recently and officers were elected. The company is capitalized for $500,000 and has taken over leases on 1500 acres of land formerly held by the Palouse River Coal & Development Co. The reports of C. E. Allen and M. M. Waters, who were employed to examine the property, state that a seam of lignite coal, about 6 ft. thick, has been encountered at a depth of 56 feet.

West Virginia

Kingwood—The Preston County Coal Co., operating at Cascade, W. Va., is crippled through lack of labor. Sufficient men are not available to work the plant to its full capacity. The Elkins Coal Co., operating in the same section, is also handicapped by lack of men.

Fairmont—It is reported that the demand for coal is so great that the Consolidation Coal Co. is trying to buy coal to assist in taking care of English contracts. The English government, to supply its needs, has bought 1,000,000 tons of American coal. Contracts are taking up the output to such an extent that little coal is being sold on new orders.

Wyoming

Sheridan—An unprecedented situation in union labor developed here recently when the operators of the coal properties in which the miners are striking brought suit for damages against the union as a body and attached the strike fund of the miners as a guarantee that when the suit is won there will be property with which to pay the damages. The operators allege a regular contract with the union and say the union broke the contract, thereby preventing the company from shipping coal and causing a heavy loss.

Canada

Merritt, B. C.—An explosion of gas at the Diamond Vale Colliery, Mar. 7, killed seven men and injured two. Twenty men, in all, were in the mine; eleven were rescued from another level than that in which the explosion occurred. The men in No. 3 level, the seat of the trouble, had been working with naked lights, and it is generally believed that they struck a pocket of gas.

Halifax, N. S.—It was recently reported that the Allan shafts of the Acadia Coal Co., at Stellarton, were on fire and that it had been necessary to wall off a considerable section of mine.

Personals

F. R. Wadleigh, fuel engineer and assistant general manager of the Chesapeake & Ohio Coal & Coke Co., recently spent several days in New York on business.

H. C. Thompson, of Winchester, and R. L. Thomas, of Lexington, Ky., who are extensively engaged in coal mining and own large coal properties in eastern Kentucky, have opened an office in the Hernando Building, Lexington.

T. E. Jones has been appointed manager of the Cahaba Coal Co.'s property, at Corydon, Ky. Mr. Jones recently made a trip to the headquarters of the company in Birmingham, Ala., and shortly after he returned, his appointment was announced.

W. L. Carter, general manager and part owner of the Barren Fork Coal Co., Pulaski County, Ky., has been made general manager of the Eagle Coal Co., of Alabama and Tennessee, and will move from Louisville, early this month, to take up his residence in Birmingham, Ala.

J. S. Miller, formerly superintendent of the Shumway mine, of the Rocky Mountain Fuel Co., at McGuire, Colo., has been appointed general manager of the Southern Superior Fuel Co.'s mines, near Walsenburg. Mr. Miller will make his headquarters in Walsenburg, although the main offices of the company are in Denver.

W. K. Robertson, E. K. Upton and C. O. Peterson, of Minneapolis, together with R. S. Waddell, G. H. Hutchinson and E. A. Danz, of St. Paul, all officials and engineers of the Northwestern Fuel Co., recently made an inspection of the company's property, at Superior, Wis., and were entertained by B. A. Galleher, superintendent of the local plant.

Thomas B. Scott, Fred Scott and George Cole Scott, of Richmond, Va., directors of the Bryan Coal Corporation, and W. C. Adams, a prominent engineer of Baltimore, Md., recently made a trip of inspection to the Bryan company's coal property, near Birmingham, Ala., in company with Frank Nelson, Jr., of Birmingham, president of the company.

William Hausemann, until recently chief mechanical engineer of the Sloss-Sheffield Steel & Iron Co., has been appointed mechanical engineer for the Pratt Consolidated Coal Co., of Birmingham, Ala., in charge of all mechanical construction at the Pratt company's numerous operations. Mr. Hausemann assumed his new duties on the first of the month.

James E. Roderick, chief of the Pennsylvania department of mines; W. B. Owens, division superintendent of the Lehigh Valley Coal Co., and Peter O'Donnell, district board member of the United Mine Workers, have been named as a committee of the Pennsylvania anthracite mine-code commission, to codify in skeleton form the state laws which pertain to the mining of anthracite coal.

H. G. Davis, division superintendent for the Lackawanna company, Kingston, Penn., and president of the Wilkes-Barre District Mining Institute, recently delivered an address before a meeting and banquet of the institute, in which he made the statement that "many mine foremen hold their certificates not from merit but by reason of other influences." This remark has stirred up a local discussion of considerable warmth.

Construction News

Zanesville, Ohio. The Crooksville Coal Co. has increased its capital stock from $15,000 to $30,000 to provide for enlargement of its plant.

Grand Rapids, Mich. Breen & Halliday, coal dealers, will build a large trestle and coal-storage bin at their Fifth Ave. yards. The plans contemplate a hoisting outfit for delivering cars over the bins.

Indianapolis, Ind. The W. I. Salee Co. will build a reinforced-concrete and steel overhead coal-storage plant of 10,000 tons capacity on its Cornell Ave. property. The plant will be electrically operated and equipped with screens, wagon scales, etc.

Birmingham, Ala. Edgar L. Adler has purchased the property of the Corona Coal & Iron Co., about 45 miles from Birmingham, and will spend about $250,000 in development and betterments to the present equipment in order to increase the output to 1,000,000 tons annually.

Industrial Notes

H. R. Setz, who has been chief engineer of the Struthers-Wells Co., of Warren, Penn., for the last two years, has just accepted the position of chief engineer with the Otto Gas Engine Works, of Philadelphia. Mr. Setz was formerly connected with several of the leading American and European gas- and oil-engine manufacturers. His particular attention will be directed toward the development of a complete line of Otto-Diesel engines of the horizontal type.

The C. O. Bartlett & Snow Co., of Cleveland, Ohio, has increased its capitalization to $500,000 in order to keep pace with its development and the rapid growth of its business. About 25 years ago Mr. C. O. Bartlett, now the company's president and treasurer, laid the foundation of this business. Its operations during the earlier years were the manufacture of general mill machinery. But gradually one line after another has been added, and the volume and importance of the business have increased to such an extent that the company now occupies a prominent position as engineers and manufacturers of all kinds of elevating and conveying machinery, complete coal tipples and coal-handling machinery at the mines and docks and complete coal- and ash-handling equipment in addition to numerous other lines of special machinery for the economical handling of practically all kinds of materials.

Book Review

PROFITS AND WAGES IN THE BRITISH COAL TRADE, 1898-1910, by Thomas Richardson, member of Parliament, and John A. Walbank. Published by N. A. C. C., 34 Grey St., Newcastle-on-Tyne. 4¾x7; 96 pp.; paper cover; 6d. net.

This book flung into the camp of the operator at the eve of a bitter struggle is of no little significance and has been so treated, it having been reviewed by the *Colliery Guardian* and *Engineering* in long editorials. It is an *ex parte* statement.

Let us take an instance from the preface, for the purpose of showing the veracity of these witnesses: "On the general question of the minimum wage it may be pointed out that while the national income increased by £225,000,000 during the 10 years ending with 1910, the share of that which came to the working class in the form of wages was under £6,000,000." Probably these facts are true if the word "British" be placed before "working class," but it must ever be remembered that the greater development of English investment is not in Great Britain but abroad, and the increase in the total wage roll has been appropriately there and not in the British Isles. Should all the increase of income go to the British working man? Rather should not some of it go to the larger body of laborers inhabiting the seven seas? The argument is typically British as it was typically Roman in Rome's decline. Just as "Bread and circuses" were to come from the looting of the Roman provinces, so the comforts of the Britannic proletariat are to come today, not from the earnings of British labor, but from the profits of capital invested the world around. If like agitation continues and British business continues to suffer from competition, it is likely that the wage roll of England will continue to decline as the income of the country rises. The recent social propaganda of Lloyd George is only possible while financed by earnings made in every country under the sun.

It seems that the English mines of the United Kingdom have had to face a decline in price from $2.19 per ton to $1.99 since 1907. Why then do these authors take a 13-year average except for the obvious purpose of making a good case?

We cannot believe any argument of profit, no matter how large, nor any proof of starvation, however distressing, can be advanced justifiably in defense of a *minimum wage*. Both indeed may well be good convincing evidence of the equity of a wage increase, when an increased rate for *piece work* is urged. If either can be proved satisfactorily, no question remains but that the duty of capital and its proved advantage is to share up its profits in the one case and to improve the physical being and, thereby, the efficiency of its laboring force in the other.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The strained condition of the market, as noted in our last issue, continues unrelieved. The preliminary meetings of the operators and miners have been even more discouraging than usual, causing additional anxiety to the consumer, and a further demand for storage coal.

The shortage is most pronounced in the East, particularly at the large distributing centers along the Atlantic coast, where it is being further aggravated by an abnormal demand for bunker coal, because of the general suspension in Europe. Deliveries still continue slow and uncertain at these points, with prices ruling firm or advancing.

Production in the Pittsburg district is estimated to be double that of last September, when the Lake shipments were at their maximum; prices are very uncertain and the market feverish, due to the acute shortage in the East. The car situation continues to be the predominating feature in Ohio. A number of embargoes declared on the Ohio roads were removed for a time, but soon put in effect again, and transportation is still in a semi-demoralized condition. Much of the West Virginia coal, destined for this market, is being diverted to the bunker trade on the coast, which is unusually heavy.

In the Middle West the market is more quiet and easy, although there is an upward trend in prices at Chicago, especially in the steam line. In the Far West the trade is normal and unchanged.

Boston, Mass.

The Eastern market is in a state of near panic, at least so far as concerns soft coal for spot delivery and in small lots. It is probable that were it not for the large off-shore demand and for the stretching of local bunker contracts due to the British strike, prices on bituminous would be little if any higher than a week ago. For small quantities, however, on cars prices have jumped to new high levels. It is only a question of time when larger buyers will have to follow suit, and if the demand keeps up from abroad there is no telling what prices may be reached. Rumors of panic prices at the Virginia terminals and Philadelphia for April and May shipment are alarming, to say the least.

Deliveries all-rail continue to be slow and uncertain. Most of the operators are positively declining orders for delivery after Apr. 1, and high prices still obtain on coal *en route* to the transfer points. The Boston retailers advanced bituminous from \$4.50 to \$5.25 on Mar. 11, and screenings from \$2.75 to \$3.25. In cities like Providence, Fall River, and Portland, the domestic sizes have also been raised from 50c. to \$1. Ordinary grades of Pennsylvania bituminous advanced sharply f.o.b. Philadelphia early in the week, as high as \$4 having been paid for Eastern shipment.

In anthracite there is little change, except that consumption has further reduced stocks. Receipts are still very small. Domestic sizes have been held in cargoes here for prices as high as \$7@7.25, the net circular being \$5.50 alongside. There is much anxiety over shipments for the rest of March. Current prices are about as follows:

Clearfield, or any ordinary bituminous, f.o.b. Philadelphia	\$3.50@4.00
Clearfield, for shipment, f.o.b. mines	2.10@2.50
Pocahontas, New River, f.o.b. Hampton, Roads	3.75@4.75
Pocahontas, New River, Boston, on cars	5.25@6.00
Pocahontas, New River, Providence, on cars	5.25@5.60

New York

The unsettled conditions, bordering on a panic, still prevail in the New York market. The larger companies are hard pressed to meet their contracts and are making sacrifices in order to do so. The older the customer the more consideration he naturally receives, but as a rule allotments are proportioned directly according to the past requirements of the consumer; some consumers are anxious to anticipate a possible shutdown at the mines and are making requisitions for extra supplies which are being refused.

The anthracite companies are inclined to be noncommittal on the outlook but claim that the situation in their department is approximately normal. The demand is heavy, but this is not unusual for this time of the year and wholesale prices are unchanged. Stocks are thought to be rather below normal and it is doubtful if any are being accumulated.

Prices for bituminous rule high and the better grades are practically unquotable. Spot bituminous is variously quoted at \$3.75@4.50 and \$4@5, with prices fluctuating almost hourly. Supplies of bituminous are believed to be only about 50 per cent. normal for this period.

Philadelphia, Penn.

Apparently it is being taken for granted that there is likely to be trouble at the mines on the first of April, judging from the preparations that both the steam users and householders are making. Consumers are awaiting with interest the result of the conference between the operators and miners, and in the meantime, are protecting themselves to the best of their ability. Public institutions and factories are not taking any chances, but laying aside all the coal they can get hold of, and judging from the demand, the egg, stove and chestnut users are of the same mind.

All sizes are in great demand, and what little stocks the dealers have are rapidly dwindling away. Pea coal is a scarce article here, and almost any price is being paid for it; as a matter of fact, there is a premium asked on all sizes in the open market, and little offering at that. Dealers who have been in the habit of shopping around for their supplies, are finding a very rough road at the present time, and paying fancy prices for what they do get.

The wholesale market still has its hands full taking care of the business offered. As far as the steam sizes are concerned, it is useless to tender orders, for they are invariably declined. Contracts already taken cover the entire output, and there is no surplus for the open market.

Pittsburg

Bituminous—Mines are operating up to the limit of car supply. A few have full car supply, but in general the mines are not able to operate up to full capacity, and an approximate estimate would be 80 per cent.; this, however, includes all mines in the district. Last September, when estimates were made of the mines operating at 50 to 60 per cent. of capacity, there were some mines entirely idle, which did not enter into the reckoning, and it is estimated that at present the output of the district is double what it was in September, with Lake shipments in full blast.

Prices are extremely irregular, and chiefly so on account of the irregular tidewater demand, prices in that market rising and falling almost hourly. Little Pittsburg district coal is going in that direction, as other districts have a freight advantage. The Pittsburg district market may be roughly quoted at \$1.40 to \$1.50 for mine-run, although sometimes considerably higher prices are bid, and occasionally sales are made at less than \$1.40. Prices for the tidewater market

are much higher, but it must be remembered that there is a freight advantage with some districts, and in addition the tidewater prices are all per gross ton, Pittsburg district coal regularly selling per net ton. For instance, a number of sales of Clearfield coal have been made at $2 per gross ton, with a freight advantage of 40c. per gross ton over Pittsburg. This price, therefore, would be equivalent to $1.60 per gross ton, Pittsburg district mine, which is equivalent to $1.43 per net ton.

We quote the Pittsburg district market approximately as follows, per net ton: Nut, $1.30@1.40; mine-run, $1.40@1.50; ¾-in., $1.50@1.60; 1¼-in., $1.65@1.75; slack, $1.10@1.25, per ton at mine, Pittsburg district.

Connellsville Coke—The coke market has undergone a sharp advance, with limited sales. Early last week prompt furnace coke was bringing $1.85@1.90 but the market stiffened steadily and at the close of the week nothing was available at under $2, while some odd lots were sold at even higher than this. Total sales were 100 to 150 cars. There has been no negotiating on contract coke as neither buyers nor sellers would be ready to consider contracts at this time. The last quotations on contract furnace coke were $1.80 to $1.90. We quote: Prompt furnace, $2@2.10; prompt foundry, $2.30@2.50.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Mar. 2 at 396,010 tons, an increase of 4757 tons, and shipments at 4521 cars to Pittsburg, 6244 cars to points West and 1125 cars to points East, a total of 11,890 cars, or an increase of 152.

Baltimore, Md.

Not for years has the Baltimore market experienced such activity as was apparent during the past week. Prices went soaring, and the supply of the fuel was by no means equal to the demand. There was an advance of from 25 to 50c. in the price on low-grade coal over that quoted for the previous week, and consumers could not get all they desired then. Last week low-grade fuel was sold at $1.50 per ton. By the middle of the week just ended, this same fuel sold freely at $1.75 and $2 per ton, and buyers were anxious to get it at those figures.

The strike in England has helped the Baltimore market to a great extent. The Consolidation Coal Co. is sending all the coal it can spare to foreign countries which had heretofore been supplied by English companies. The Davis Coal and Coke Co., is now loading 6000 tons of coal at Port Covington in this city for the British Navy. Numerous inquiries have also been received by this company from other sources, and it is believed that these will develop into business. The possibility of a strike in the organized bituminous fields has also helped the local market as the bituminous consumers are not at all certain that an agreement will be reached between the miners and operators.

In the face of the marked activity in the local market, the Baltimore operators have also had to contend with unfavorable car movements. The railroads have not yet been able to procure their full quota of cars from the West, and as a result the shortage in the East still continues. It is expected, however, that the situation will improve during the coming week.

The coke market still continues quiet. Some little coke is being moved under contract, but spot business is practically at a stand still.

Buffalo, N. Y.

There is a regular split in prices as regards Buffalo and other points in this territory, for it is easy to bring in bituminous from the mines, so that the Buffalo prices are easy while at the same time many other points in this district where there is a shortage are paying almost any price. The market is feverish and unsettled and liable to change at any time. The average dealer is getting hold of all the coal he can and selling it at a fancy price. He is, however, confronted by the extra demand from his regular customers, which is so urgent that there is little surplus.

Prices are pretty nearly unquotable, being nominally $2.60 for three-quarter, $2.50 for mine-run and $2.25 for slack. At the same time the consumer who is short will pay almost any price for a quick supply. In some districts there are mills already shutting down because they are not able to get coal at any price.

The railroads are moving freight faster than they did a month ago, but they have not by any means caught up, the worst of the situation being that there are so many empty cars to return to the mines.

The anthracite situation is not much relieved, except that the consumption is reduced. It will be some time before there is any surplus. The demand is heavy and it is going to be heavier in the Lake trade the coming season than ever before. The anthracite authorities claim that they are not likely to be able to meet the demand in this and the Western territory.

Cleveland, Ohio

Conditions in the past week have been even worse than the week previous, on account of the car shortage, and the situation at the present writing looks serious. Unless a better supply of cars is furnished in the very near future, there certainly will be a coal famine, at least in this district.

A great deal of coal has been shipped from the West Virginia points to this market during the winter, and the dealers are expecting to get the greater part of their supply from that district should the expected strike materialize, but in the past week it has been impossible to get quotations from that section, because of the extraordinary demand to supply ocean liners. The West Virginia operators have been getting prices ranging from $2 to $2.25 on mine-run for all the coal they can furnish. The general impression is that should the English miners hold out any length of time, the West Virginia people will not ship coal here when they can obtain such high prices in the foreign markets. While there has not up to the present, been any real suffering, there certainly is great uneasiness for the future.

Prices have advanced in this market from 25 to 50c. per ton on all grades, and are especially strong in slack. There seems to be a varied opinion as to whether a strike will take place, the majority seeming to think it will, while others say that a suspension of two or three weeks will be the result.

Columbus, Ohio

With embargoes on practically all of the railroads running north and west of Toledo, the car situation in Ohio shows little signs of improvement. The congestion at Toledo and other way points is still the worst feature of the coal trade, and it will require a long time to relieve the situation. As a result of this the coal traffic is still in a semi-demoralized condition.

Some headway was recently made at Toledo in clearing away the congestion, and several roads removed the embargo which has been in effect for some time, but within a few days it was again declared. There is believed to be 12,000 cars at least in Toledo for shipment into Michigan and Indiana points, and there is little likelihood of their removal for the time being, at least.

Under these conditions prices have been ruling firm in all grades of coal, and in every Ohio mining district. Spot coal for steam purposes is at a good premium, and the same is true of domestic sizes in certain localities. Only the railroads have been able to store up for a suspension, and manufacturing establishments have had all they can do to get a supply of fuel for their current needs. Mines in most of the Ohio districts have been operated on a 50 to 65 per cent. basis, while at some points they have been compelled to close down entirely for a portion of the past week.

The steam trade is the most active department of the business. Retailers are desiring coal, but their orders in transit are large and they are not placing many new ones at this time.

Retail trade has been rather brisk under the present weather conditions, and dealers have been selling many small orders to tide over consumers. Prices prevailing in Ohio fields are as follows:

Hocking Valley	
Domestic lump	$1.60
¾-in.	1.40
Mine-run	1.15
Nut	1.15
Nut, pea and slack	0.95
Coarse slack	0.85
Pittsburgh, No. 8	
¾-in.	$1.30
Mine-run	1.10
Coarse slack	1.10
Pomeroy Bend	
Domestic lump	$1.75
¾-in.	1.50
Nut	1.30
Mine-run	1.5
Nut, pea and slack	1.00
Coarse slack	1.00
Kanawha	
Domestic lump	$1.50
¾-in.	1.30
Mine-run	1.10
Slack	0.75

Hampton Roads, Va.

It is impossible to give any standard prices for coal at present writing for it is selling at all kinds of prices, without much regard to quality.

Sales of standard New River and Pocahontas coals have been made at $2.85 per gross ton f.o.b. Hampton Roads, while the same descriptions have also brought as high as $4.25. At the present time, it is difficult to get any coal for less than $3.50 f.o.b. Considerable amounts of high volatile fuels have been sold for ships use and such have brought as high a figure as the standard bunker coals.

Coal is moving fairly well to tidewater over all the railroads, but by far the greater part of it is being applied on contracts and there is little free coal; there is still a shortage of both cars and locomotives. The United States Navy has had great difficulty in obtaining any extra coal and it is rumored that some of the present navy contractors will find themselves in a difficult position when the department asks for new bids. There are now a large number of ships lying off the various coal piers and the situation is growing worse every day.

The prospect of a strike in the anthracite and bituminous fields seems more likely and even if the British miners return to work by the end of next week, it will be a long time before conditions become normal again. The large selling agencies are finding it difficult to decide on the best policy to pursue, whether to refrain from making their usual contracts for the coming contract year, in order to have plenty of free coal and take advantage of the present high prices, or to go on and close contracts for the usual amounts. Bids on the Panama Canal contract will be due before Apr. 1 and the figure at which this contract is let, usually determines, to a large extent, the tidewater price for the coming year.

Charleston, W. Va.

As has been the case for several months the output of coal in this state is governed entirely by the car supply. This shortage continues so pronounced that the mines are in operation only about half the time. The demand for coal is good, and the prices are by no means poor when compared with figures of recent years, but with the railroads suffering from a lack of motive power, and unable to keep the cars in motion, the operators are not getting the benefit of the betterment in prices that they feel they should.

The publication of some of the statistics available as a result of the completion of the report by John Laing, Chief of the Department of Mines in this state, for the year 1911, occasioned much surprise in many quarters. Despite the fact that West Virginia is losing hundreds of thousands of tons of coal in trade, it is the belief of the officials connected with the Mining Department that the output for the coming year will show an increase equal to that of the year just closed.

Nashville, Tenn.

The good cold weather still continues here, which is unusual for this section of the country at this time of the year. The car situation has improved a little, and there is still a big demand for coal, which will probably continue up until Apr. 1. After that time, if there is a suspension of operations in Illinois and Indiana, the nonunion fields in west Kentucky will have more business than they can handle and at a very high price. It is likely that the coming week will see quite a good deal of steam and domestic coal shipped from this field, both into Chicago and St. Louis.

The operators all up and down the system are very bullish. Prices are the same as they have been for the past few weeks, except in screenings, which have advanced from 5c. to 10c. a ton over what they have been for the past three weeks, and indications are that they will be much higher the coming week.

Indianapolis

The production of coal and the sale at the mines at good prices, principally for storage purposes, has been carried on at a rather lively pace during the past week. The big demand has given a good tone to the home market, especially in the steam trade, which has largely offset the weakening due to milder weather and the lessening of the demand for domestic. While this demand is general, it is not, according to reports, as heavy as was the case two years ago.

The car situation, while improved, is not satisfactory. Blockades at terminals and way points have delayed the arrivals at destination, and, as a consequence, their return to the mines. Retail dealers are complaining that coal ordered a month ago has not been delivered and their supply is very low. While the big factories are being cared for, the small consumers are suffering because the retailers cannot get the coal. The former are taking advantage of the situation to store up for the strike or suspension, which everyone seems to believe inevitable. Retail dealers say that the railroads are storing and that this is responsible for the car shortage.

Chicago

There is a strong upward tendency in the market for steam coal as a result of the announcement that a suspension at the mines Apr. 1 is practically certain. There is an indication of weakness in the domestic market, the retailers believing that spring and warm weather are not far distant.

A distinct flurry in the steam market is expected within a short time. Prices have already moved up 10 to 15c. a ton, especially on steam lump and screenings. Smokeless coal is practically off the Chicago market except for those shipments which are made to satisfy contracts. Dealers here would be willing to pay $1.25 to $1.35 for smokeless mine-run. Anthracite producers have shipped very little coal into the Western market recently as a result of demands for current needs and storage purposes. There is a strong demand for coke, the supply being short.

Prevailing prices at Chicago are as follows:

Sullivan County:	
Domestic lump	$2.62
Egg	2.62
Steam lump	$2.37@2.57
Screenings	2.12@2.22
Springfield:	
Domestic lump	$3.05
Steam lump	$2.32@2 [illegible]
Mine-run	2.12@2.22
Screenings	2.07@2.12
Clinton:	
Domestic lump	$2.57
Steam lump	$2.3[illegible]@2.42
Mine-run	2.17@2.27
Screenings	2.02@2.12
Pocahontas and New River:	
Mine-run	$3.25@3.55
Lump and egg	4.05

Coke—Prices asked for coke are: Connellsville and Wise County, $4.85; byproduct, egg and stove, $4.95; byproduct nut, $4.75; gas house, $4.90@5.

Minneapolis—St. Paul

Although there is a distinct shortage of coal here, prices are not in proportion to those generally prevailing at this time of the year when stocks are so nearly depleted and with the strike problem confronting the trade. Prices in the Twin Cities on steam coal are not very steady as there has been a lot of surplus coal dumped into this market. Steam consumers are not inclined to accept the strike talk and are holding for low prices.

Dock men say there is very little coal on the docks at the present time and not very much chance of getting any from the East before Apr. 1. Experienced Lake men report that navigation on Lake Superior cannot possibly open up until a few days before June 1, which is fully a month later than is generally the case. Anthracite coal is very scarce at the docks and a number of the companies reported "no stock" on the larger sizes in their March 1 circulars. One and three-quarter million tons of the different sizes of anthracite were disposed of by the docks at the head of the lakes during the past year and one well known authority states that there is not more than 20,000 or 30,000 tons on all the docks and a great portion of that is booked for shipment.

Prices at the docks are very good and there is no necessity to cut as they will have no trouble disposing of what little coal is left in stock now.

St. Louis, Mo.

The St. Louis market on all coals is more erratic than it has been for two years. Last Saturday, Standard lump coal sold as high as $1.85 for 2-in., while Carterville 6-in. was hanging on at from $1.75 to $1.85. Standard screenings went to $1.35, while Carterville screenings were selling at $1.25. This is largely accounted for by the fact that there is only a limited tonnage of Standard on the market, as the railroads are buying it up, whereas there is considerable Carterville, the railroads refusing to touch this on account of the 15c. higher freight rate.

The dealer trade seems unable to get stocked up on account of the prevailing cold weather, the month of March thus far being one of the most severe in a long time. There is a slight chance that the market will break the latter part of the present week, but it opened strong with everything to indicate that it would remain so. It is almost impossible to get Standard screenings, and nut is out of the question. The washed coal market is exceedingly strong on account of the demand for mine-run.

The market opened Monday about as follows:

Franklin County	
Lump and egg	$2.00@2.25
No. 1 nut	2.00@2.15
No. 2 nut	1.85@2.00
No. 3 nut	1.60@1.75
2-in. screenings	1.20@1.25
Carterville	
Lump and egg	$1.85@2.00
No. 1 nut	1.75@1.85
No. 2 nut	1.65@1.75
No. 3 nut	1.45@1.50
Screenings	1.15@1.25
Mine-run	1.35@1.45
Standard	
6-in. lump	$1.90@2.00
2-in. lump	1.75@1.85
Screenings	1.20@1.30
Mt. Olive	
3-in. lump	$1.90@2.00
No. 1 nut	1.60@1.65
No. 2 nut	1.50@1.60

The market is good on anthracite at the circular, and coke is moving freely. There is some smokeless moving in, but not in the volume that it has been in the past.

Portland, Ore.

Winter is now apparently over here and the demand for fuel is accordingly light. Wood has declined until cordwood can now be bought for $5 per cord, delivered in the city, whereas last fall it was quoted at $7 and $7.50. No decline has been noted in coal values, however, but the fact must be considered that at no time during the winter did the price rise above that charged early in the fall. The season has been a dull one for fuel dealers.

San Francisco, Calif.

California has been keeping up its climatic reputation and the weather for the past week has been adverse for the coal men. Apart from kitchen requirements, little coal has been needed to meet domestic wants; consequently the movement has been far from brisk. Heavy rains are expected, however, which will tend to cause an increased demand.

The imports of foreign coal for January comprised 14,690 tons from British Columbia, 9780 tons from Australia, and for February, 11,950 tons from British Columbia and 1620 tons from Australia. Car shipments from the East and Middle West were very light. Dealers had laid in full stocks to meet the winter demand, which did not materialize; consequently they have considerable on hand.

The U. S. Government last year brought into San Francisco 135,000 tons of Pocahontas for navy use, and it is understood that the government has engaged tonnage for about 130,000 tons, for delivery this year. Last week the navy department contracted with a local stevedoring company to discharge the coal at 15½c. per ton of 2240 lb., the department doing the hoisting and taking care of the coal from the ship's hatchways.

Current prices to the trade continue as follows, per long ton:

Wellington (British Columbia)	$8.00
Pelane Main (Australia)	8.00
Eastern	8.50

Production and Transportation Statistics

Pennsylvania Railroad Co.

Statement of coal and coke carried on the Pennsylvania R. R. Co.'s lines East of Pittsburg and Erie for the month of January, 1912, in short tons:

Anthracite	1,040,535
Bituminous	3,581,365
Coke	940,931
Total	5,562,831

Anthracite

Shipments of anthracite in February amounted to 5,875,968 tons, as compared with 5,070,948 tons in February, 1911. This is an increase of 805,020 tons and sets a record for the month of February. The Philadelphia & Reading led in volume of shipments last month with 1,202,536 tons; the Lehigh Valley was second, with 1,083,925. Shipments of the Central Railroad of New Jersey were 785,000 and of the Delaware, Lackawanna & Western 782,699 tons.

Financial Notes

Contract between Lehigh Valley Coal Co. and Lehigh Valley Coal Sales Co. provides for purchase of the coal on usual 65% basis, i.e., at 65% of its market value determined by New York tidewater price.

The Chicago, Indianapolis & Louisville has sold to Redmond & Co. and the Equitable Trust Co., both of New York, $2,500,000 first mortgage sinking fund 5 per cent. bonds of the Monon Coal Co. The bonds are being offered at 94 and interest.

A letter has been addressed to bond and stock holders of the Sheffield Coal & Iron Co. requesting them to deposit their holdings with the Bankers' Trust Co., pending the submission of a plan of reorganization by a protective committee consisting of James Gayley, Alfred Clifford, August Heckscher, Randall Morgan and W. R. Walker.

The committee for the reorganization of the Pennsylvania Coal & Coke Co. has given notice that, pursuant to the plan and agreement for the reorganization, depositors of certificates who have complied with said plan, are entitled under the terms thereof to receive certificates of stock in the reorganized company known as the Pennsylvania Coal & Coke Corporation.

The Herbert Collieries Corporation, which has its principal offices at 17 Battery Place, New York, and is engaged in mining coal on leased lands in Fayette and Raleigh Counties, W. Va., filed a voluntary petition in bankruptcy giving liabilities of $224,085 and assets of $169,898. According to the petition, the company owes the Guaranty Trust Co., of New York, $75,000, fully secured by leasehold mortgage 6 per cent. 10-year sinking fund gold bonds, H. L. Herbert, New York, $122,233 and Earle & Russell, New York, $15,000 for legal services. The assets, the petition states, include leases of mines in West Virginia valued at $150,000; stock in a mine store at Herberton, W. Va., worth $10,000 and debts due aggregating $6598.

The Belleville Savings Bank, as holder, it is stated, of $14,000 bonds, brought suit in the Circuit Court at Belleville, Ill., to foreclose the mortgage of 1905, under which $1,100,000 bonds were issued to the Southern Coal & Mining Co., of East St. Louis, Ill. It is alleged that the interest and sinking fund payments are in default and that the business is improvidently handled. An official states that the suit will be opposed on the ground, among others, that the terms of the mortgage require a majority of the bondholders to join in a foreclosure suit, that the company has been unable to meet its interest payments for about a year and a half, but if it were left alone now it would soon be on its feet again, as it has been earning about $10,000 a month since September, 1911.

COAL AGE

Devoted to Coal Mining and Coke Manufacture

Volume 1. No. 24.
Issued Every Saturday.
Hill Publishing Company.

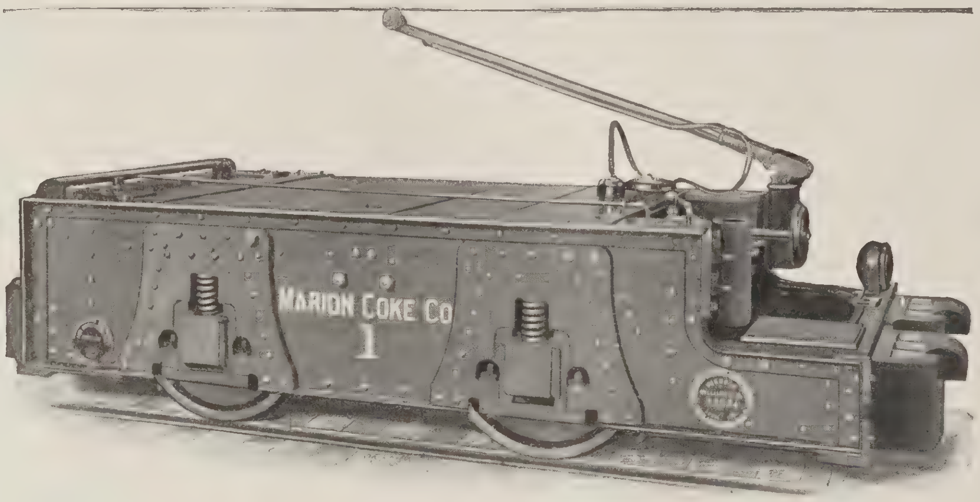
NEW YORK, MARCH 23, 1912

Ten Cents per Copy.
U. S. and Mexico, $3 per Year.
Canada, $4; Other Countries, $5.

A Modern Underground Hospital

In the Brisbane Colliery of the Delaware, Lackawanna and Western Company, hewn out of the solid coal and rock. The walls are covered with whitewashed concrete; the room is heated by steam and lighted by electricity. The electric wires are carried in conduits, and a steel stand is provided on which a stretcher may be laid. The patient in the illustration has one leg in splints and the attendant is bandaging his fractured skull.

Baldwin-Westinghouse Electric Mine Locomotives



Some Mechanical and Electrical Features:

Steel Frame Construction
Practically indestructible. The frames may be bent, but not broken.

Commutating-Pole Motors
No sparking, even under extreme overloads. Great endurance.

Oil-Waste Lubrication
Long life of bearings—Oil economy—Low maintenance.

Baldwin-Westinghouse Mine Locomotives have reduced operating cost and increased production wherever introduced. Ask for data.

Address either company

COAL AGE

Vol. 1 NEW YORK, MARCH 23, 1912 No. 24

To onlookers, and in fact to most people who are not active participants in the controversy, a "strike is a strike"—nothing more, nothing less. Labor wants a larger share of capital's profits. Production is curtailed, money and muscle measure strength, and after a temporary suspension, there is victory for one or a compromise for both.

Do we exhibit sufficient individual intelligence when we reason in this elementary way, and when we look forward to a strike with the same complacence as we do to a periodical change in season? Through the purchase of an overcoat we are able to repel the sting of winter, but the erection of a fence topped with barbed wire won't check the advance of present-day thought, even though it may prove a satisfactory barrier to the forcible trespass of dissatisfied employees. Labor unrest and its recurrent outbursts, are a phase of social evolution, a type of development that never goes backward.

However, if present labor leaders and the operators who now sit in authority were to exchange places in life, these identical fences would be built; the fights would occur with equal frequency and the same increasing severity. Not a letter in the principles of the combatants would be changed. With no less certain growth, the idea would prevail that "the laboring man will never be stronger than the government—he *will be* the government." The change will be effected by evolution, not revolution or socialism.

And getting to the bottom of some matters made prominent in present labor controversies, is a delicate operation. The men want more money because of the higher cost of living; however, we see some similarity in this problem and the question as to whether "the Bowery is tough because bad men live there, or whether the men are tough because the Bowery is bad."

It's the same old story of cause and effect, and frequently we have a way of construing effect for cause. It's a game where the sky is the limit and a few players hold all the good cards. Before long, clerks in stores will ask us how much money we have in our pocket before telling us the price of an article.

It's also interesting to note the effect of strikes on an industry. To begin with, let us lay down one general rule: The injury resulting from a suspension is in inverse ratio to the size and importance of the business affected. When the trouble is local and but few people are concerned, the fight is generally bitter and both parties to the conflict oftentimes are ruined. But in a branch of productive activity as great as coal mining, where the securities of the corporations are widely distributed and the product of the companies is a common necessity, too much is at stake; too many people are disturbed, and the contending parties are obliged to settle their differences or have their noses rubbed together by a power greater than they.

In the meantime, strange to relate, the effect of such trouble is quite contrary to what we generally anticipate or suppose. For months previous to the probable strike, business is stimulated; the men make better than average money and the operators enjoy a good market at higher prices. The suspension occurs and tired bodies and overworked machinery are given a rest.

During the period of idleness, engineering departments and mine officials turn their thoughts to the rehabilitation of exhausted plants, and accept the situation as an opportunity to install new equipment and inaugurate improved methods.

Everyone is aware the deadlock will end and the wheels turn again. It may be a few weeks, or several months, but when a settlement does come, the lost ground will be recovered, and a period of activity with good prices will again prevail. Already, on the eve of trouble, we can record that coal men, especially bituminous, for the first time in years have had a prosperous season, and many operators who recently haven't been on speaking terms with Uncle Sam's currency, are smiling and bowing just as though no estrangement had occurred.

And from the standpoint of better engineering practice and all-round progress, there's a resulting advance not to be ignored. The tendency of the mine owner is to supplant men with machinery—for the first time he is impressed with the enormous appetites of mules as compared with motors; he discovers that machines do the work of many miners, and such facts cause him to slip the band from off his wallet when no other arguments could avail.

The year before the recent Illinois strike, the increase in the number of mining machines was 3.5 per cent.; in 1910, the year of suspension, the increase in machines was 8.1 per cent. So let us view the matter in a sensible way and recognize the benefits as well as the evils. The chief sorrows of life are our worries about troubles that never come to pass.

The Cambria Coal Field in Wyoming

A coal mine with a romantic history is rather out of the ordinary in so humdrum an industry as the mining of this commodity usually presents. But in Wyoming there is a coal mine that has a romance attached—a romance not of love or intrigue, but a romance of commercialism, railroad building, and empire constructing.

By Jesse Simmons*

A description of one of the earliest coal operations in the West. Compressed air is used for both haulage and mining; the peculiarly irregular character of the bottom has made the adoption of the puncher type machine imperative. A long tail-rope haulage system is in use.

Historical

In the year 1889 the Burlington & Missouri River R.R., now a part and parcel of the Chicago, Burlington & Quincy system, had built as far as Alliance, Neb., but the powers that were hesitated to continue farther until a coal supply could be assured. At that time the nearest coal operation was in Iowa, and this was too great a distance to haul fuel for operating engines through a section of country that was but sparsely settled.

Kilpatrick Brothers & Collins were contractors who had built a large portion of the line to Alliance, and they were told that there would be no further Westward extension unless coal could be secured. This big contracting firm immediately put scouts in the field and after a diligent search the Jumbo mine, near Newcastle, Wyo., was discovered. Tests proved the coal to be a splendid grade of engine fuel, developments disclosed a large body, and the work of continuing the railroad Westward was resumed. When the rails were laid to the coal camp, which had meanwhile been named Cambria, the mine was ready to commence shipping, and from that date until the present time the mines have been operated continuously, producing in the interim 8,600,000 tons of coal.

During this period the Jumbo mine has been worked out—the last pillars being drawn last fall—and operations are confined to the four workings known as Antelope Nos. 1, 2, 3 and 4. A company was organized under the name of the Cambria Fuel Co., controlled by Messrs. Kilpatrick Brothers & Collins, which operated the mines until January, 1910, when a new corporation under the name of The Cambria Fuel Co., financed by New York and Pennsylvania people, purchased the property and holdings of the original company.

The coal is classed as bituminous and is one of the few mines in the state of Wyoming producing this grade of fuel. For a number of years a battery of beehive ovens were operated, the coke being sold to smelters in the Black Hills district of South Dakota. The suspension of these smelters curtailed the market for coke and none has been made for a number of years.

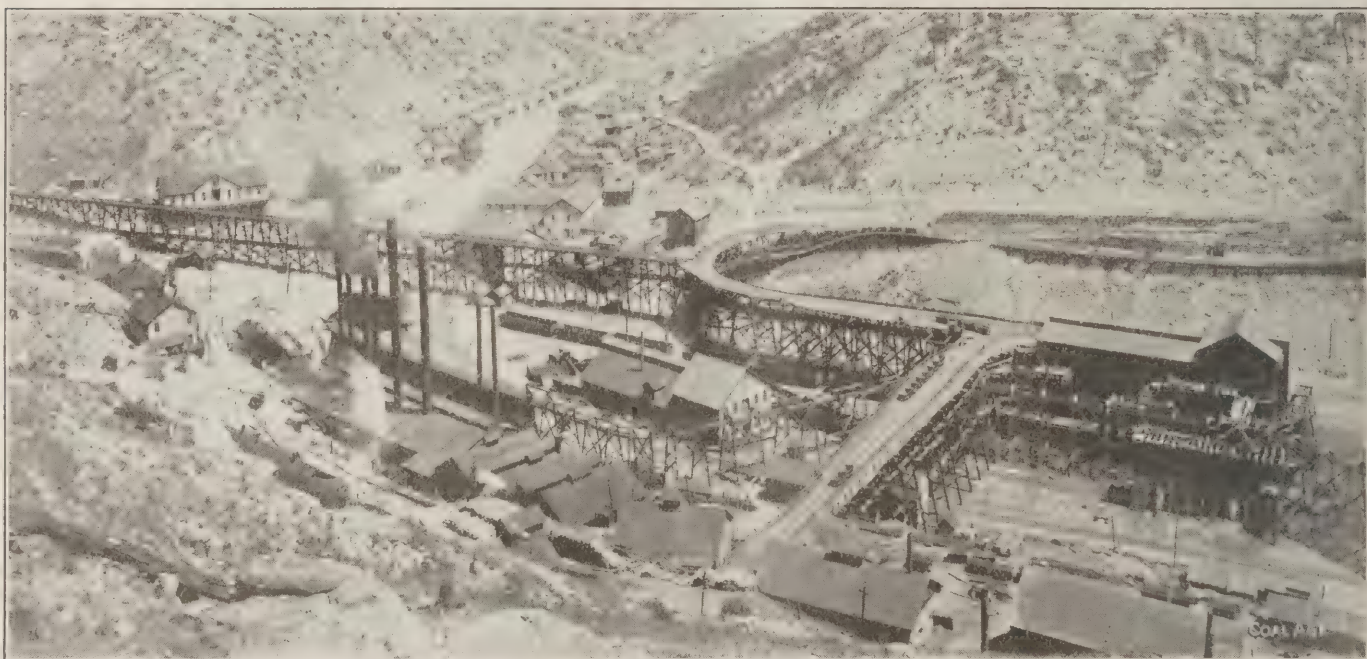
A peculiar feature in connection with the coke was the fact that it carried gold. The coal itself, upon repeated tests, is shown to contain some gold, many assays giving returns as high as $2 per ton, but the content is naturally higher in the coke. Assays made on 31 railroad cars showed the coke to have an average gold content of $2.74 per ton, some of the assays showing as high as $5.60 per ton.

Cambria is on the southwesterly edge of the Black Hills uplift, and gold is almost universally distributed throughout that section. This geological fact probably has a bearing upon the occurrence of gold in this coal.

Geological Formation

The coal of this district occurs in the lower Cretaceous formation, near the bottom of the Lakota sandstone. N. H. Darton, in a description of the Newcastle quadrangle, Folio No. 107 of the Geologic Atlas of the United States, says of the Lakota formation:

> The Lakota formation is one of the most prominent members brought to the surface by the Black Hills uplift. It is mainly a mass of sandstone of considerable hardness, which, together with the overlying Dakota sandstone, gives rise to the prominent hogback rim of the hills. Its prominence is enhanced by the softness of the underlying shales, above which it rises in high cliffs. Its thickness usually varies from 150 to 200 ft., but locally the amount may be somewhat greater. The sandstones are coarse grained, cross-bedded and massive, with partings of shale or thin bedded sandstone of no great thickness. The color varies from light gray, or even white, to buff, the last named being most frequent.



General Surface Arrangement at Cambria Fuel Co.'s Mines

*Deadwood, S. D.

At or near the base there is a coal horizon, in which coal of excellent quality attains the thickness of from 5 to 7 ft., in an area of moderate extent about Cambria. This coal appears not to occur east and south of the gap in which the range is crossed by Stockade Beaver Creek. . . .

The coal in this area varies greatly in thickness and purity, but, as shown on the map, there is a large area in which it is 5 ft. thick or more, and in places it reaches a thickness of over 7 ft. . . . The principal bed of purer, thicker coal trends Northeast and Southwest, its center passing through Cambria.

The Principal Mines

The seam has a sandstone floor and roof, which are quite irregular. Apparently the formation in this locality was affected by the geological action which brought the Black Hills to the surface. This territory is on the southwest edge of the Black Hills uplift.

In the vicinity of Cambria the principal topographic feature is a plateau cut by cañons from 300 to 400 ft. in depth, and their numerous shallower gulches and tributaries. The main opening on the vein lies near the bottom of Cambria Cañon. Running westerly this entry, in following the coal, crosses Camp Cañon on a trestle and passes underground on the westerly side of the bridge.

A large portion of the best coal area has been found under the plateau lying between Camp Cañon and East Plum Creek. At this point are located the mines known as Antelope Nos. 2 and 3. These mines extend toward the west. Antelope Nos. 1 and 4 mines extend parallel with Cambria Cañon, to the north. Workings advanced northerly in Nos. 1 and 4 have made necessary a long, roundabout haul to reach the tipple, and work is now under way upon an entry northwesterly from the tipple to give a more direct haulage route from these mines. The Jumbo mine, which lies east of Cambria Cañon, has now been entirely worked out.

Forty drill holes have been put down at various points on the property, the average depth being 252 ft. to the bottom of the coal. The deepest hole was 308 ft. to the bottom of the coal. The discrepancy in the depth is accounted for both by the contours of the surface and the dip and rise of the vein.

System of Working

Main entries are driven 12 ft. wide in the clear, and cross entries the same width. The cross entries are turned off from the main entry at intervals of 600 ft., and from these, rooms 20 ft. in width are driven at intervals of 40 ft., thus leaving 20 ft. pillars. In this way rooms are about 300 ft. in length. As fast as the rooms are worked to their extreme length, the pillars are drawn, and the old workings are stopped up as fast as completed.

Cross entries to the west have a uniform dip and those to the east a uniform rise. In some cases the rise in cross entries is as high as 10 per cent. In the main entry, which, it will be borne in mind, has a north and south course, the floor dips and rises at various points—in some places the grade being as high as 5 per cent., which is the maximum for the main entry.

View of Miners' Houses at Cambria, Wyo.

However, the rise and fall of the seam averages about level, as is shown by the following figures: From the mouth of the pit, to the face of the main haulage entry, a distance of 1¾ miles, the floor of the seam rises and falls a number of times, but the end of the entry and the pit mouth are on absolutely the same level, as are also the three west cross entries farthest developed.

The mine has been worked for approximately 20 years and experience has shown that the seam will average in the neighborhood of 6 ft. in thickness. At points it pinches down to 3 ft., but it has been found economical and advisable to mine this thickness in order to follow up the body to points where it will open up larger.

Machine Mining and Ventilation

Ingersoll punchers are used for undercutting, as experience has proven that the coal is too hard, and the floor too uncertain to make chain machines practicable. The floor will often dip or rise sufficiently in the length of a cut to either leave coal at the bottom of a cut made by a chain machine, or else the cut will enter the floor. The cut made by the puncher machine is 4 ft. 6 in. or 5 ft. in depth, and an average machine man can take care of 6 or 7 rooms during his shift. The coal is then drilled with breast drills, the holes being 3 ft. 6 in. to 4 ft. in depth and 1¼ in. in diameter. Three of these holes are sufficient to break the face of a room. Black powder, fired by squibs, is used in blasting and each miner does his own loading and firing.

The low pressure air line, which serves the punchers, is 8-in. common pipe for the full length of the main entry. The cross entries are piped with 3-, 4- and 5-in., and every room is supplied with 1½-in. pipe.

The mines are remarkably free from explosive gases, due no doubt to their proximity to the surface, and fact that the coal is overlaid by a coarse-grained porous sandstone. The freedom from gas makes ventilation a simple problem and eliminates the necessity of the many safeguards ordinarily necessary in coal mining. During the time that this mine has been in operation there have been no explosions, nor any fires of consequence.

Six Capell exhaust fans are used for the three operating mines—four of these being driven by compressed air, and two, which are located about 200 ft. from the power house, are driven by steam.

Haulage System

Wooden cars, with loose wheels (which, by the way, are being replaced by Whitney wheels as fast as they are worn out) having a capacity of 3800 lb., average, are drawn by horses from the rooms to the small partings, one and two cars being the average trip for one horse. From these small partings compressed air locomotives take the coal in 10-car trips to the main parting in the main haulageway; the capacity of this parting is 60 loaded cars. Trips of 39 cars are made up on these partings and delivered to the tipple by a tail-rope haulage system 8200 ft. in length.

All tracks are 42-in. gage, and 50-lb. rails are used in the main entry, 40-lb. in the cross entries and in the rooms 16-lb.—these latter being the lightest rails used in the mine.

Underground 36 horses and 7 H. K. Porter, compressed air locomotives are used in handling the coal; three of these are 5-ton, three 7-ton and one 10-ton. They are charged with air at 800 lb. pres-

sure at the charging stations, which are from 1 to 1½ miles from the compressors. At the compressors 1000 lb. pressure is carried, giving about 800 lb. at the charging stations. The charging stations are never more than 3000 ft. apart, and the locomotives will ordinarily run twice this distance on one charge.

The high pressure pipe line is 4 in. inside diameter, and is reduced to 3 in. for the last 1000 or 1500 ft. As fast as the entries are extended, the 3-in. pipe is taken up and replaced by 4-in., so that the maximum amount of the former is about 1500 ft. Extra heavy wrought-iron pipe ($\frac{5}{16}$ in. in thickness) is used.

Surface Plant

There are two frame tipples, almost identical in construction and equipment. After weighing, the coal is dumped and the empty cars returned on a track below the main track to a station at the pit mouth, hooked to the tail-rope system and returned to the mine. As the product of this mine is divided into two classes, viz: slack and 4-in. lump, the latter being used as locomotive fuel, the preparation consists merely of crushing, picking and screening.

The coal as dumped from the mine cars drops into a Jeffrey 30-in., two-cylinder crusher, and is crushed to 4 in. From the crusher the coal is delivered to a sheet-iron picking belt, 4 ft. 6 in. wide and 60 ft. in length. Two men, one on either side of this belt, standing near clutch levers which disengage the power-driven belt, pick the waste material, which is dropped through a chute into a car underneath the tipple and removed to the dump. The coal from the end of the belt drops over a 4-in. grizzly where the slack is separated from the lump.

The boiler house contains 1500-hp. boiler capacity. Of this, 1000 hp. is generated in Heine water-tube boilers, and the balance in return-flue boilers. The boilers are hand fired and the ashes drop to a cellar below the boilers into buggies, and are conveyed to a dump in the cañon.

The power-house equipment includes 7 Norwalk compressors and 2 dynamos. Five of the compressors are 2-stage machines, compressing to 150 lb. pressure, and two are 3-stage machines compressing to 1000 lb. The dynamos are 75 kw. and 35 kw. respectively, generating direct current at 110 volts. The former is used for lights in the camp and mine and the latter for operating the conveyor systems, machine shop, etc. The machine shop is equipped for making all necessary small repairs to cars, puncher machines, etc.

Water Supply

The company owns the town of Cambria also the water-works system, and supplies water to the town of Newcastle and the C. B. & Q. Ry. at that point. Newcastle is an up-to-date town of 2000 inhabitants.

A large portion of the water comes from a well 2345 ft. deep, the casing in which is 8 in. in diameter at the top and 6 in. at the bottom. An air-lift is used to bring this water from the bottom of the well to a tank 100 ft. above the top of the well, on the side of the cañon; air at 800 lb. pressure is used for this work. The pipe line to the bottom of the well ends in two nozzles, one $\frac{3}{32}$-in. and the other $\frac{5}{32}$-in. in diameter, which form the outlet for the air. It has been found that the smaller nozzle gives a solid column of water through a 4-in. pipe into the tank mentioned. The total flow under normal conditions amounts to 325,000 gal. per 24 hours. Additional water is developed in neighboring cañons by means of dams and reservoirs.

The superintendent, Mr. Naysmith, has had experience in the manufacture of plate glass, and is authority for the statement that all the necessary material, ideal in quality, for the manufacture of a high-grade plate glass occurs on the property, and it is quite likely that experiments in the manufacture of glass will shortly be undertaken.

The Cambria Fuel Co.

This company owns 17,000 acres of land, about one-third of which is underlaid with coal, speaking of which Mr. Darton* says:

> A coal bed averaging 6 ft. in thickness contains about 3,000,000 tons of coal per square mile, but there is considerable loss in working. There are now in the Cambria coal fields about 10 square miles underlain by coal that would average 5 ft. or more in thickness, so situated that it is available for working, which on this estimate would yield a total tonnage of 30,000,000 tons.

Following is an average analysis of the coal:

Moisture	5.86
Volatile matter	40.44
Fixed carbon	40.45
Ash	13.25
	100.00
B.t.u.	11,247

The mine is 7 miles from the town of Newcastle, a station on the main transcontinental line of the C. B. & Q. Ry. The product is used almost exclusively for steam coal, the screenings going to steam plants and the lump to the railroad. Exposure to the weather has no appreciable effect on this coal, for the railway has a large quantity which has been in a pile exposed to the weather for years, and it is as good today as it was when so placed. The capacity of the mines would probably average, if pushed, 2000 tons per day, but the output is now from 1550 to 1800 tons per day. In the report of the state mine inspector of Wyoming for the second district, year ending Sept. 30, 1910, the production of the Cambria mines is given at 412,108 tons and the number of employees 484.

*Folio No. 107, Geologic Atlas of the United States.

The seam contains slate bands an inch and upwards in thickness; when it is 10 ft. thick there may be as many as three or four of these bands. Under the terms which are in force between the company and the miners union, the men take care of 2 in. of this waste matter, and receive additional compensation for anything above this amount.

The camp is known as Cambria, and a view of it is reproduced herewith. The cottages are neat and well constructed and the character of the employees is well exemplified in the neat manner in which they keep their homes. The buildings owned by the company include not only the homes of the employees, but a club house, general store, meat market, three churches, school, etc.

The Cambria Fuel Co. has an authorized capital stock of $2,000,000, divided into $1,500,000 common stock and $500,000 preferred stock. There is also a bonded indebtedness, on which the interest is being promptly met, and a sinking fund provided for its retirement. The officers are: B. F. Overholt, Scottsdale, Penn., president; L. T. Wolle, Akron, O., vice-president; Walter Schoonmaker, Cambria, secretary and treasurer and Robert Naysmith, Cambria, superintendent. To the two latter gentlemen, Messrs. Schoonmaker and Naysmith, the writer wishes to acknowledge the many courtesies which have made it possible to present this article.

Briar Hill Coal Co.

The Briar Hill Coal Co. owns 1440 acres of patented land, 14 miles from Cambria, on which 600 ft. of development work has been done, opening up a seam similar to the Cambria coal. The seam is so located that it cannot be opened by drifts, and shafts have been sunk for the purpose of exploiting the beds. The coal is of a quality practically the same as the Cambria, and occurs in the same formation, viz: the bottom of the Lakota sandstone.

The property is 48 miles West of Nahant, a station 19 miles from Deadwood and Lead, S. D., on the C. B. & Q. Ry., and 7 miles from Osage, a station on the transcontinental line of the same road, Northwest of Newcastle. A railroad with a maximum grade of 0.7 per cent. can be built from the mines to Osage at a trifling cost, and 20 miles remains to be built with a road running Westward from Nahant. This would give a connection with the Black Hills, a district that consumes a large amount of coal. This road would have a maximum grade of 2 per cent. The workings show from 7 to 9 ft. of clean coal, with a good roof.

The officers of this company are: W. H. Lyman, Kewanee, Ill., president; Geo. S. Jackson, Deadwood, S. D., vice-president; R. F. McLaughlin, Sheridan, Wyo., secretary and H. W. Trask, Kewanee, Ill., treasurer.

Coal Mine Ventilating Equipment

By W. M. Weigel*

Theory of centrifugal fans. Formulas are here derived which express a number of important relations and determine certain values that are required for calculating the size and proportions of a fan to work under given conditions. Methods and apparatus for the measurement of air pressures. The seventh of a series of articles on mechanical ventilators.

The theory of the centrifugal fan is probably understood less thoroughly than that of any other mechanism which is used to an equally great extent. The basic principles of its operation are, of course, well known but such matters as the effect of different shaped blades and the efficiencies obtainable at various capacities and speeds are determined usually by purely empirical methods or by experiment. A comparison of tests on different fans is rarely a fair way of deciding their relative worth because different methods are employed for determining the pressure and volume of the air and these measurements are frequently made at different points in the circuits. Moreover, published results seldom state whether the pressure given is the static pressure, that due to velocity or the total pressure.

The following demonstration is taken, with some modifications, from Weisbach and Herman's "Mechanics of Air Machinery." Since the pressure generated by mine fans seldom or never exceeds a water gage of 10 in., which is equivalent to less than 6 oz. per sq.in., or a 2½ per cent. increase or decrease in the weight of the air, and since most fans operate at pressures ⅙ to ¼ of this value, it introduces no appreciable error to assume that the weight of air per cubic foot is equal at the inlet and outlet of the fan.

Taking the case of a fan wheel with the blades curved backward from the direction of rotation, as shown in Fig. 1, let r_1 equal the inner, and r_2 the outer, radius of the blades, the form of one of which is shown by AB. Assume that the air, entering the wheel in the direction of the axis C, is deflected radially so that any particle of air will enter the wheel at A with the radial velocity, in feet per second, $AD = v_1$. In order that the air may enter between the rotating blades without impact, the inner circumferential velocity of the wheel, $AE = u_1$, must equal v_1 *cot.* α, where α is the angle FAL between a tangent to the inner end of the blade and a tangent to the circumference at this point. Under this condition the velocity, $c_1 = AF$, with which the particle of air begins its travel along the vane, is given by the equation:

$$c_1^2 = v_1^2 + u_1^2 \qquad (I)$$

Velocity of Efflux

The fan wheel now exerts an accelerating action on the air until it leaves at the outer circumference. Let it be assumed that the particle of air under consideration leaves the wheel at the instant at which the outer tip of the vane, B, has reached the position B'; then this particle has described an absolute path which we will assume is represented by the curve AB', tangent to the radial velocity of entrance v_1.

The air leaves the wheel with an absolute velocity equal to v_2, tangent to the absolute path AB', and this velocity must be regarded as the resultant of the outer peripheral velocity $u_2 = B'H' = BH$ and the velocity relative to the wheel, $c_2 = B'J', = BJ$, with which the air moves along the last element of the vane.

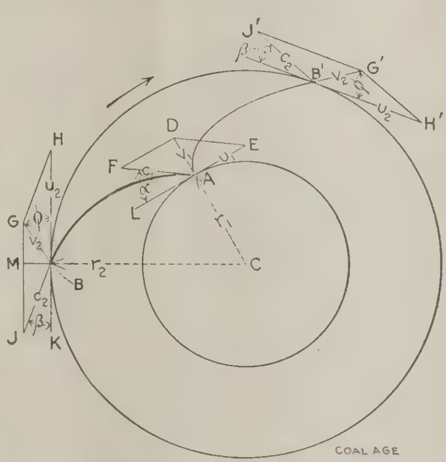


Fig. 1. Velocity Diagram

Then from the figure, if ϕ is the angle, $G'B'H' = GBH$, at which the air leaves the circumference of the wheel, we have:

$$c_2^2 = v_2^2 + u_2^2 - 2\ v_2\ u_2\ cos.\ \phi \quad (II)$$

The entrance velocity v_1, is in all fans generated by the pressure of the atmosphere. Let f = coefficient of resistance to entrance of the air into the wheel. Then $h_o = (1 + f)\ \frac{v_1^2}{2g}$ where h_o equals the head of air necessary to generate the velocity v_1, and consequently the absolute pressure at A is less than that in the fan drift by the above amount. With a blowing fan, the air is taken freely from the atmosphere and the absolute pressure outside the inlet is equal to the atmospheric pressure. For an exhaust fan, this pressure outside the inlet is smaller than the atmospheric pressure by a certain amount, depending on the resistance of the mine.

Let h_1 = static pressure above the atmospheric existing in the fan drift just outside of the inlet, expressed in feet of air column. For exhaust fans h_1 is negative and for blowing fans $h_1 = 0$. Let x = total absolute pressure of the air at A, expressed in feet of air column and, b = atmospheric pressure in feet of air column. Then

$$x = b + h_1 - z_1 - \frac{v_1^2}{2g} \qquad (III)$$

where

$$z_1 = f\frac{v_1^2}{2g}$$

which is the head corresponding to the resistance to entrance.

Again, let h_2 = the static head of air, above the atmosphere, at the end of the outlet; that is, at the end of the discharge opening, and let w = the velocity with which the air leaves the outlet to enter the atmosphere or the fan drift as the case may be; also let z_2 = head corresponding to the resistance of the outlet. The air leaving the wheel at B', with the absolute velocity v_2 possesses a certain absolute static pressure which we will call y, and must be able to overcome not only the resistance, $b + h_2$, at the orifice of the outlet, but also the resistance z_2 and, moreover, must retain a velocity, w. Under the assumption that the weight of air per cubic foot is the same at the inlet and outlet, we then have the equation:

$$y + \frac{v_2^2}{2g} = b + h_2 + z_2 + \frac{w^2}{2g} \qquad (IV)$$

With blowing fans h_2 is a positive quantity, and with exhaust fans $h_2 = 0$.

Acceleration of Air Passing through Fan

The preceding equations, I to IV, relate to the entrance and exit of the air with regard to the fan. The following equation, V, expresses the accelerating influence of the vanes.

The increase in energy imparted to the air in flowing from A to B', is equivalent to the difference in the heads due to the peripheral velocities at these points, or we can write:

$$y + \frac{c_2^2}{2g} - \left(x + \frac{c_1^2}{2g}\right) + z_r = \frac{u_2^2 - u_1^2}{2g} \qquad (V)$$

in which z_r is the head of air necessary to overcome the resistance to the passage of air through the blades.

Substituting in V the values of c_1, c_2, x and y as obtained from equations I to IV, we have after reduction:

*Associate professor of mining, Pennsylvania State College, State College, Penn.

$$h_2 - h_1 + z_1 + z_2 + z_r + \frac{w^2}{2g} = \frac{2\, v_2 u_2 \cos.\, \phi}{2\, g}$$

Let

$$(h_2 - h_1) = h$$

and

$$(z_1 + z_2 + z_r) = z$$

and the equation reduces to:

$$g\,(h + z) + \frac{w^2}{2} = v_2 u_2 \cos.\, \phi \qquad \text{(VI)}$$

From Fig. 25 we also have:

$$v_2 = u_2 \frac{\sin.\, \beta}{\sin.\, (\beta + \phi)} \qquad \text{(VII)}$$

Substituting this value of v_2 in VI and solving for u_2 gives:

$$u_2 = \sqrt{\left[g\,(h + z) + \frac{w^2}{2}\right] \frac{\sin.\, (\beta + \phi)}{\sin.\, \beta \cos.\, \phi}} \qquad \text{(VIII)}$$

This equation gives the peripheral velocity when the pressure, and discharge velocity and angles β and ϕ are known. Now, if the vanes end radially, $\beta = 90°$ and equation VIII reduces to

$$u_2 = \sqrt{g\,(h + z) + \frac{w^2}{2}} \qquad \text{(IX)}$$

Axial Depth of Fan

From the Fig. 1, it is seen that the radial velocity with which the air leaves the wheel is: $BM = v_2 \sin.\, \phi$ and for substitution in this equation, the value of v_2 may be taken from VI. Let l_1 and l_2 represent the axial widths of the blades at the inner and outer circumferences respectively. Then, since the quantity of air Q entering the wheel is the same as that leaving it we have the relation:

$$Q = 2\,\pi r_2 l_2 v_2 \sin.\, \phi = 2\,\pi r_1 l_1 v_1 \quad \text{(X)}$$

from which

$$v_1 = \frac{r_2 l_2}{r_1 l_1} v_2 \sin.\, \phi$$

In nearly all mine fans $l_1 = l_2$, so that this equation becomes:

$$v_1 = \frac{r_2}{r_1} v_2 \sin.\, \phi \qquad \text{(XI)}$$

From the figure, the angle made by the inner end of the vane with the circumference is obtained, or,

$$Tan.\, \alpha = \frac{v_1}{u_1}$$

If the angle ϕ is not known or assumed beforehand, but some other quantity is given, say the entrance velocity v_1, which can be obtained from equation X, $v_1 = \frac{Q}{2\,\pi r_1 l_1}$, an equation for determining the peripheral velocity may be derived as follows: In equation VI, $v_2 \cos.\, \phi$, represents the tangential component MG of the absolute velocity of efflux. From the figure $MG = BH - MJ = u_2 - v_2 \sin.\, \phi \cot.\, \beta$ and combining this with XI

$$v_2 \cos.\, \phi = u_2 - \frac{r_1}{r_2} v_1 \cot.\, \beta$$

Substituting this value in equation VI

$$g\,(h + z) + \frac{w^2}{2} = u_2 \left(u_2 - \frac{r_1}{r_2} v_1 \cot.\, \beta\right)$$

and solving this for u_2

$$u_2 = \frac{r_1}{2\, r_2} v_1 \cot.\, \beta + \sqrt{\left(\frac{r_1}{2\, r_2} v_1 \cot.\, \beta\right)^2 + g\,(h + z) + \frac{w^2}{2}} \qquad \text{(XII)}$$

This gives us the peripheral speed for a given static pressure h_1 in terms of the radii of the wheel, the angle made by the tips of the blades with the circumference, the inlet velocity, the velocity at the orifice of exit, and the fan resistance.

Effect of Curving Blades Forward

With h and w remaining constant, u_2 decreases as the angle β increases. When

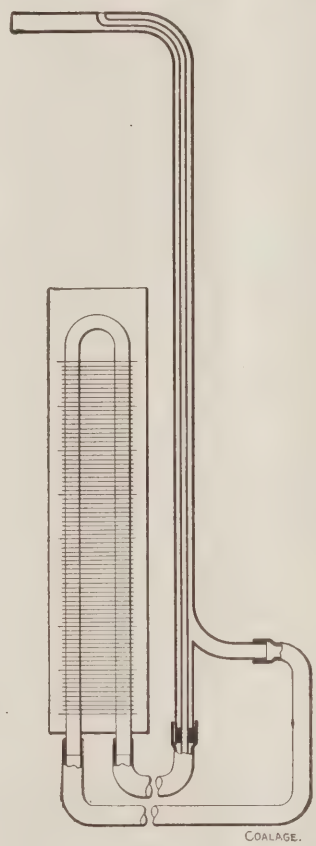

Fig. 2. Pitot Tube

$\beta = 90$ deg., $\cot.\, \beta = 0$, and equation XII reduces to equation IX. If β is greater than 90 deg., then $\cot.\, \beta$ becomes negative and the value of u_2 is still further reduced, the other quantities remaining unchanged. This accounts for the construction of several modern forms of fans, in which the blades curve forward beyond a radial position at the circumference.

The total dynamic pressure of the air is made up of the static pressure h, and that due to the velocity w. This total pressure is, moreover, due entirely to the absolute velocity v_2 of efflux. By referring to Fig. 1, as well as to equation XII, the effect of increasing the angle β is made clear. In the figure, v_2 is the resultant of u_2 and c_2, so that by increasing the angle β, the angle between c_2 and u_2 is decreased with a corresponding increase in the resultant velocity; c_2 being tangent to the last element of the vane at all times.

To obtain the number of revolutions per minute, n, from the peripheral speed we have:

$$60\, u_2 = 2\,\pi\, r_2\, n$$

and

$$n = \frac{60\ u_2}{2\ \pi\ r_2} \qquad \text{(XIII)}$$

Capacity and Pressure

From equation X,

$$Q = 2\,\pi\, r_1\, l_1\, v_1$$

and

$$l_1 = \frac{Q}{2\,\pi\, r_1\, v_1} \qquad \text{(XIV)}$$

If, now, we make the velocity v_0 of the air at the entrance to the fan equal to that at the inner circumference of the wheel;

$$v_1 = v_0$$

and letting

A = The area of the inlet;

$$A = \frac{Q}{v_1}$$

and

$$l_1 = \frac{A}{2\,\pi\, r_1}$$

If the radius of the inlet is the same as the inner radius of the wheel, which is quite common practice, then

$$l_1 = \frac{\pi\, r_1^{\,2}}{2\,\pi\, r_1} = \frac{r_1}{2}$$

In fans so designed, the width is nearly always made greater than the theoretical value, to allow for the slowing of the air caused by resistances at the entrance. Actual values of l_1 vary from $0.6\, r_1$ to $0.8 r_1$, with an average of $l_1 = 0.7\, r_1$.

The pressure or head of air z necessary to overcome the frictional resistances of the fan to the passage of air, depends first upon the volume of air passing, and second upon the mechanical construction. The work expended in overcoming the resistance is lost, and should be reduced to a minimum. This is done by providing ample inlet area, keeping the velocity of the air within reasonable limits by having a fan of proper size, providing a conoidal surface opposite the inlet to deflect the entering air into a radial direction without eddying, and shaping the spiral casing to allow a free outlet.

Theoretical Pressure

In equation IX, the total pressure of the air is divided into three parts, the static head h, the head necessary to overcome the fan resistance z, and that due

to the velocity w. Equation IX may be written:

$$u_2^2 = g\,(h + z) + \frac{w^2}{2}$$

or

$$\frac{u_2^2}{g} = h + z + \frac{w^2}{2g}$$

Now let

$$H = h + z + \frac{w^2}{2g}$$

the total fan pressure, then is

$$H = \frac{u_2^2}{g} \qquad \text{(XV)}$$

which is the equation commonly used to represent the theoretical total pressure developed by a centrifugal fan with spiral casing, in which

H = The total dynamic pressure in feet of air column,

and

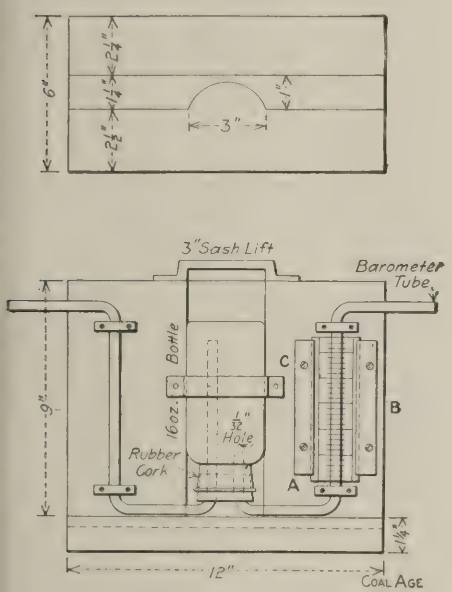

FIG. 3. SPECIAL MANOMETER

u_2 = The peripheral velocity of the tips of the vanes in feet per second.

With an open-type fan, discharging freely into the atmosphere around the entire circumference, the pressure due to the velocity of the air leaving the wheel is lost, and it may be shown that the theoretical pressure due to such a fan is one-half that of one with a spiral casing, or

$$H = \frac{u_2^2}{2g} \qquad \text{(XVI)}$$

From equations IX and X we have the general principles that:

1. Under any given conditions the dynamic pressure produced by any centrifugal fan varies as the square of the speed of rotation.

2. The volume delivered by any centrifugal fan varies directly as the speed of rotation.

Equivalent Orifice

This term, as applied to the ventilation of mines, was proposed by Murgue, and was formerly more used than it is at the present time. Two equivalent orifices were usually stated, that of the mine and that of the fan. The equivalent orifice of the mine was an imaginary opening in a thin plate of such a size that it offered the same resistance to the passage of a given quantity of air as did the mine. That is, it would take the same pressure to pass the same volume through the aperture in the plate as through the mine. The equivalent orifice of a fan is likewise that opening in a thin plate which offers the same resistance to the passage of a given volume of air as does the fan.

Let

a = Equivalent orifice of the mine,

and

o = Equivalent orifice of the fan.

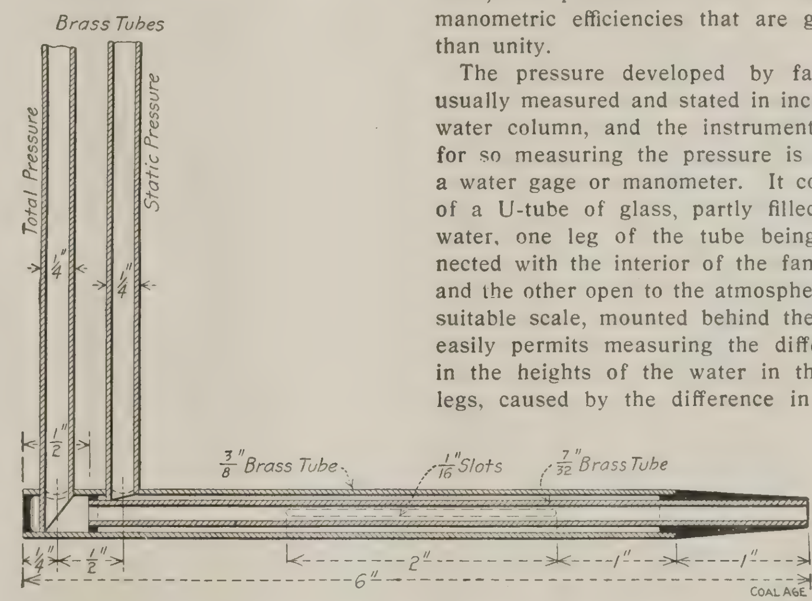

FIG. 4. MANOMETER FOR PRESSURE READINGS

Then from the law of flow of a fluid through an orifice in a thin plate:

$$Q = 0.65\ a\,v;$$

and

$$Q = 0.65\ o\,v';$$

in which

v and v' = Velocities of air passing through a or o, and are also the velocities due to a head of air h or h' feet high;

or

$$v = \sqrt{2\,gh}$$

and

$$v' = \sqrt{2\,gh'}$$

From the above:

$$a = \frac{Q}{0.65\sqrt{2\,gh}}$$

$$o = \frac{Q}{0.65\sqrt{2\,gh'}}$$

About the only value these quantities have is in making a comparison of the resistances of two mines or two fans.

Efficiency of Fans

In discussing the work or operation of a fan, three efficiencies are usually involved, which, while interdependent to a certain extent, vary in their importance. They are:

1. Manometric efficiency.
2. Mechanical efficiency.
3. Volumetric efficiency.

The manometric efficiency of a fan is the ratio of the actual pressure developed by the fan to the theoretical pressure. The theoretical pressure is universally calculated according to the formula $H = \frac{u^2}{g}$. This is the theoretical pressure for a fan with radially ending vanes, and, as some of the modern fans have the tips of the vanes curved forward, it is possible to obtain values for manometric efficiencies that are greater than unity.

The pressure developed by fans is usually measured and stated in inches of water column, and the instrument used for so measuring the pressure is called a water gage or manometer. It consists of a U-tube of glass, partly filled with water, one leg of the tube being connected with the interior of the fan drift, and the other open to the atmosphere. A suitable scale, mounted behind the tube, easily permits measuring the difference in the heights of the water in the two legs, caused by the difference in pressure between the atmosphere and the air in the fan drift.

The correct measurement of the pressure of the air requires considerable skill and proper apparatus. There are two pressures, the *static pressure* and the *velocity pressure*, and the sum of these is equal to the total or dynamic pressure.

To measure the static pressure, the end of the tube inserted into the fan drift must be parallel to the direction of the current, so that there will be no tendency for the air to blow into the end or to blow away from the end. To measure the total pressure, the end of the testing tube must be normal to the air current, so that the air will flow directly against, or into, the opening. The velocity pressure is then the difference between the total pressure and the static pressure. The velocity pressure may be measured directly by connecting the static-pressure

tube to one leg of the manometer and the total-pressure tube to the other; the reading of the manometer then gives directly the pressure due to the velocity.

Shape of Tube Ends

Experiments have shown that the shape of the ends of the testing tubes makes a considerable difference in the readings. Every precaution should be taken to prevent eddying or impact around the ends of the tubes. The best results are obtained by having the end of the velocity tube slightly coned on the outer surface, so that the edge surrounding the opening is practically a knife edge, and offers the least possible resistance to the air. A good form of apparatus combines both tubes in one, as illustrated in Fig. 4, and this is the type adopted by the government engineers for making fan tests. Another form is shown in Fig. 2, and illustrates the method of connection with the manometer.

There is apt to be considerable oscillation of the surface of the water in the two tubes, and this makes accurate readings difficult. To overcome the difficulty, Messrs. O. E. Jager and Geo. C. Westley proposed the manometer illustrated in Fig. 3. [*Engineering and Mining Journal*, Vol. 88, p. 468.]

In this apparatus, the bottle shown is really one leg of the U-tube, but its area is so large, compared to that of the small tube, that the rise and fall of the surface of the water in it may be neglected and the readings are then taken from the zero position of the water in the tube to the side. The end of this tube projecting up into the water in the bottle is drawn out to a fine aperture, which neutralizes the oscillations.

Recording pressure gages may be had which show the pressure developed throughout the 24 hours. They may indicate static pressure only, or total pressure, as desired, and are a valuable accessory of a ventilating plant.

The British Coal Trade Crisis

Special Correspondence

Continuation of diary of events leading up to the present labor crisis in England. The conciliatory attitude of the government and its strenuous endeavors to effect an agreement, are unique features of the present situation.

(*Continued from p.* 604, Coal Age, *Feb.* 17.)

Feb. 12—A special conference of the miners' delegates, from the districts embraced within the English Conciliation Board area, was held to receive a report from their representative, on the Conciliation Board, with reference to negotiations with the coal owners. Power was given their representatives to continue negotiations with the owners on the question of an individual wage, the understanding being that the whole Federation agrees to a settlement thereon.

Feb. 13-14—A special conference of the Miners' Federation of Great Britain resolved:

That we express our regret that the coal owners have refused to accept the principle of an individual minimum wage for all men and boys employed underground, as we know that there can be no settlement of the present dispute unless this principle is agreed to. In view of the fact, however, that we have no desire for a serious rupture in the coal trade of the country, we are willing to meet the coal owners at any time to discuss the matter if the coal owners express a desire to do so.

It was then decided that the conference stand adjourned, to be called together when the officials and the Executive Committee find it advisable.

Feb. 13-16—Miners in the various districts, numbering 400,000, hand in their notice to cease work. Some of them, in Hobbs and Derbyshire, where they have already a partial acceptance of the principle of a minimum wage, do so reluctantly. For instance, at the Mansfield colliery, employing 1941 men, only 914 gave notice on the appointed day.

Conviction strengthened that a national stoppage cannot be avoided, one leader describing the position as "dark as midnight." Panic prices again rule on the coal markets. Figures published by the Registrar of Friendly Societies show that the finances of the various miners' unions, in the federation, in relation to their numbers were, on Dec. 31, 1910, as follows:

		Membership
Dunham	$2,340,930	121,805
Derbyshire	1,623,700	37,428
South Wales	751,150	137,553
Notts	953,275	30,944
Lancashire	447,835	60,461
Northumberland	409,465	37,361
South Derbyshire	71,585	3,622
North Stafford	176,990	8,143
Cannock Chase	80,275	9,400
Pelsall (Staff)	67,145	4,059
Warwickshire	79,880	10,000
Yorkshire	1,763,030	88,271
Cleveland (M. & Q. Asso.)	81,580	9,326
North Wales	41,190	12,043

Feb. 19-20—Negotiations suspended in Scotland, Northumberland and Durham, while in South Wales there is a deadlock. The Conciliation Board for England resumed negotiations, but late in the afternoon of Feb. 20, it was announced that their efforts to secure a settlement had definitely failed. The government took prompt action, and Premier H. H. Asquith at once issued a letter to both sides, inviting the leaders to confer with the cabinet. At the same time the coal owners made public their proposals for a settlement and the conditions on which they are prepared to accept the principle of an individual minimum wage for underground workmen.

Feb. 21—Official statement issued by the miners' leaders as to the conditions on which the demand for a minimum wage is based, and will be accepted, for all underground workers. The statement forms a reply to the terms offered by the owners. A comparison of the terms shows that the differences have practically been narrowed down to the question of the guaranteed individual minimum wage to the coal hewer working on contract in a normal place who fails to earn his wage on tonnage output of coal. The difference now may be briefly stated at 12 or 14c. per day.

Feb. 22—The situation was discussed at meetings held in the Foreign Office between representatives of the government and of the coal owners of Great Britain and the Miners' Federation, respectively. Mr. Asquith and his colleagues met the trade union officials in the morning and again in the evening, having in the meantime consulted with a large and representative body of coal owners. The Prime Minister invited the national conference of miners to meet him on Tuesday, Feb. 27.

Feb. 23—Prime Minister received in audience by King George, who, it is understood, desired to hear from his chief adviser personally the progress of the negotiations. Conference of lord mayors and mayors of England and Wales, convened by the lord mayor of London to consider what action they can take in the interests of conciliation and the public weal in the present coal-trade crisis. Government representatives met the members of the coal owners' committee for the purpose of further consultation, the proceedings being adjourned to Monday, Feb. 26.

Feb. 24—The *London Daily Chronicle* says a definite step forward has been taken. The government is reported to have submitted to both the miners and the coal owners certain proposals which they have been asked to discuss and to answer on Tuesday, Feb. 27. The secret has been so carefully guarded that only the four miners' representatives and the leaders of

the coal owners consulted know the purport of the proposals.

Feb. 24—Conference of 170 mayors convened by the lord mayor of London passed a resolution calling upon the leaders on both sides to "recognize the paramount claims of the community, which outweigh in importance any conceivable difference that may divide them." A committee of five was formed to watch events and take such steps as may seem advisable.

Feb. 26 to *Mar.* 1—Negotiations between the government and representatives of the owners and men separately and jointly proceeded during this period of five days. Prime Minister Asquith submitted the following proposals for a settlement of the dispute:

1. His Majesty's government is satisfied, after careful consideration, that there are cases in which underground employees cannot earn a reasonable minimum wage from causes over which they have no control.
2. They are further satisfied that the power to earn such a wage should be secured by arrangements suitable to the special circumstances of each district, adequate safeguards being provided to protect employers against abuse.
3. His Majesty's government is prepared to confer with the parties as to the best methods of giving practical effect to these conclusions by means of district conferences between the parties, a representative appointed by the government being present.
4. In the event of any of the conferences failing to arrive at a complete settlement within a reasonable time, the representatives appointed by his Majesty's government to decide jointly any outstanding points for the purpose of giving effect in that district to the above principles.

The foregoing proposals were considered by all the parties involved in the dispute, and on Feb. 28 it was announced that "the coal owners of the federated area accept the proposals put forward . . . . the government to make such arrangements as will enable them to look forward with confidence to the due performance of agreements entered into in the future, and to secure that such agreements shall be binding on both sides for some reasonable period." The employers in Durham and Cumberland also accepted the proposals.

Measured on the basis of output, 60 per cent. of the owners thus signified willingness to accept the government terms. Of the remaining owners, those in Scotland adhered to the 1909 agreement, but stated that they were "prepared to meet the employees' representative with a representative of the government to arrange methods to prevent any injustice, and to fix remuneration in abnormal places." In cases of dispute, they are prepared to agree that in the event of such meeting failing to arrive at a settlement, the matter should be referred to the decision of a neutral chairman. The Welsh coal owners passed a resolution adhering strictly to the present agreement, terminating Mar. 31, 1915. The representatives from Northumberland, Forest of Dean, Somerset and Bristol were unable to accept the proposals, but on the following day, Feb. 29, the Northumberland owners reversed their decision.

The conference of the Miners' Federation passed a resolution, in which they "repeat that there can be no settlement of the present dispute unless the principle of an individual minimum wage for all underground workers is agreed to by the coal owners. We are still willing to meet the coal owners at any time they desire to discuss the minimum wages of each district, as passed by special conferences of this federation." A resolution, passed on Feb. 29, made it clear that what the men mean is acceptance of the "schedule rate for each district," as presented on p. 604 of COAL AGE.

Feb. 29—In a speech to the miners' delegates, the Prime Minister announced the government's recognition of the fact that the coal supply is the life blood of the country's industry, and of the consequent fact that reasonable conditions of coal getting lie at the root of the national existence. The government, as a result, had come to the conclusion that a case had been made out for the establishment —with adequate safeguards—of a reasonable minimum wage. As 60 per cent. of the coal owners had also assented, there was a strong presumption that the conclusion was a just and sensible one. They did not intend that the existence of a dwindling minority of employers should indefinitely delay the attainment of the object.

The miners had next to consider the best way to give effect to it. A terrible responsibility would rest upon those who clung to any particular schedule rate and so hindered the negotiations; they must allow a reasonable latitude of discussion in regard to particular rates, and the government must be allowed to discuss with both miners and owners whether each figure was reasonable. Their determination was to establish the principle of a minimum wage in the mining industry—by agreement if possible, by other means if necessary.

Mar. 1—As their notices expired, the men in various parts of the country had "downed tools" during the week, and on this day practically the whole of the kingdom's force of a million colliers came out on strike. There were further meetings between the government mediators and the contesting parties, but under the plea of existing agreements, the Welsh and Scottish owners were obdurate, while notwithstanding the powerful appeal made to the miners by the Premier, their representatives were stubborn in their opposition to the fourth of the government's proposals. In the circumstances, negotiations were suspended over the week end, and Premier Asquith informed the House of Commons that he hoped to make a full statement on Mar. 4.

[*The above diary is published as a matter of record for future reference and not because of its news value. More recent events will be printed in a later issue.*—EDITOR.]

The Colliery Manager in India

According to a correspondent in the *Capital* (India), the mine manager's life there is far from being one continual round of pleasure. The conditions noted are not entirely unknown in this country and a point is raised which should receive the careful consideration of all capitalists interested in coal-mining.

He says:

"I believe I do not overstate the case, when I say that one hears out here of more changes in the managers of collieries in twenty weeks than one does at home in twenty years. Here a manager assumes charge of a place, and in what state, in many cases, does he find it? Machinery with loose motion and neglected, pumps out of order, lots of the lower workings under water, tram lines in bad order or not sufficiently extended, coal worked away where it should not have been, possibly to an extent such as to endanger the mine or a large area of it, ventilation faulty—in fact, a general state of chaos.

The new man has in consequence to set to and put the place in order, and, of course, has to spend money in the process. That puts up his cost per ton. The blue pencil wallah notes this, and presently out the new man goes. Another man comes on, and for a time is able, owing to the work partially done by his predecessor, to show fairly satisfactory results. Naturally such results do not last.

There are so-called 'managers' at some pits in Bengal who are nothing of the sort in the proper sense of the word. They are figure heads, or dummies, merely carrying out orders from Calcutta offices. One cannot, of course, altogether blame the men; they know that non-compliance often means the sack, though at the same time they are doing or following a course which their professional experience tells them is against the interests of the colliery as such. All this is probably unknown to the owners (*i.e.,* shareholders), and if they did know, I am not sure that they would care, so long as a dividend for the time being is forthcoming, and it does not appear to be realized by the gentry who sit in Calcutta offices, under electric punkas, and so effectually wield the before-mentioned blue pencil.

News of the Coal Strike Situation

Special Correspondence

The situation in the anthracite field points to a long suspension, following Apr. 1. The bituminous controversy will probably be settled without any great difficulty. News of foreign strikes.

The demands of the anthracite miners have been formally refused, and the miners have likewise declined to consider the counter proposition made by the operators to renew the existing agreement for a period of three years. No further negotiations are in sight and it is thought that the policy committe of the miners' union, meeting in Cleveland, Mar. 25, will recommend a suspension of work in the hard-coal region, starting Apr. 1. Independent anthracite operators have issued a statement favoring an increase of wages and demanding a decrease in freight rates by the coal-carrying roads. One colliery near Pottsville, Penn., has announced a 10-per cent. advance in wages, effective Apr. 1.

While the situation in the anthracite field must be regarded as serious, and a suspension of at least five or six weeks most probable, the indications are that no great difficulty will be encountered in bringing the bituminous negotiations to a satisfactory conclusion. The joint-scale committee of miners and operators reconvened in Cleveland Mar. 20, but probably nothing decisive will be accomplished prior to the meeting of the miners' policy committee on Mar. 25.

Anthracite Conferences

The meetings of the anthracite operators and miners in New York, Mar. 13 and 15, were decidedly brief and practically confined to the exchange of formal ultimatums, although opportunity was left for a resumption of negotiations. Neither the demands of the miners nor the counter proposition of the operators was discussed.

The statement presented by the operators, takes up each demand of the miners separately and gives reasons for rejecting it. In regard to a recognition of the union, it quotes the award of the 1902 strike commission, to the effect that the United Mine Workers, being largely an organization of bituminous miners and including only a small proportion of anthracite mine workers, is not a desirable party with which to enter into contractual relations.

The proposal for a one-year agreement is rejected as being opposed to the lessons drawn from the strike commission's work and as having proved unsatisfactory when tried in other fields.

The "check-off" system is held to be contrary to a statute of the State of Pennsylvania requiring "the payment to employees by employers of the full amount of wages or earnings in cash." The conciliation board is defended on the ground that for nine years it has "assured a steadiness of work and freedom from wasteful strikes" and that the knowledge of its existence has in itself tended to allay distrust and bitterness. In regard to payment by weight it is stated that the strike commission found this to be impracticable and that the same conditions prevail now as then.

Replying to the demand for a minimum rate and an advance of 20 per cent. in wages, the statement reads:

> We call attention to the fact that in 1900 there was an advance of 10 per cent.; that in 1901 there was an advance of 10 per cent., and a further increase of 4.6 per cent., resulting from the operation of the sliding scale. A comparison of the years 1900 and 1911 shows there has been a total increase of 26.4 per cent.
>
> In addition to these considerable increases, there has been an increase in the opportunity for work, from an average of 165 days in the years from 1897 to 1901, to an average of 210 days for the five years from 1906 to 1910, both inclusive, and a still further increase was had in 1911.

The statement goes on to point out that the contract miner does not average more than 5 to 7 hours a day of actual work and it is submitted that ample opportunity exists for a substantial increase in the earnings of the miners without resorting to an increase in rate.

In conclusion, the miners are urged to accept a renewal of the present agreement for three years.

The position assumed by the operators precluded any discussion of the miners' demands and in their formal reply, delivered Mar. 15, this point is dwelt on as follows:

> Your proposal to renew the present agreement does not appeal to us nor will it to the people we represent. The award of the coal-strike commission was not intended to continue in effect for all time thereafter regardless of how materially industrial and other conditions might change and does not adequately meet changed conditions now in effect, and we submit that conditions have changed since that award was made, notwithstanding your claim to the contrary.
>
> All subjects contained in the mine workers' demands are worthy of the most serious consideration and discussion by both parties in interest, and we had hoped that the answer to them would have been such as to have at least permitted of the fullest and freest discussion of these vital subjects that mean so much to the anthracite-mine industry, but, inasmuch as your proposal to renew the present agreement is final, this renders the hope of arriving at a satisfactory conclusion by reason of such discussion quite impossible, while the position of your committee is continued in this respect.

The fact is emphasized that the cost of living has increased since the award of the commission in 1902, and in support of their demands this contention is set forth:

> The occupation of the anthracite-mine worker is admittedly a most hazardous one, hundreds of them being killed and injured each year. And we know of no good reason mine workers should be obliged to work longer hours in the anthracite coal mines of Pennsylvania than mine workers employed in the bituminous mines of the same state as well as in the chief coal-producing states of the country.

Great Britain

At the close of the third week of the British coal strike, the conferences brought about by the government, between owners and miners having been unsuccessful, a bill has been introduced in the House of Commons with the specific purpose of settling the present difficulty. The proposed enactment will be effective for only three years and will provide for a reasonable minimum wage for the miners with safeguards to protect the owners against deficiency of output. The rates are to be determined by the district boards. Considerable opposition to the measure is in evidence. The Unionist party has decided to oppose the measure, but the government hopes to have the act in force by the coming week.

Germany

The strike in the Westphalian coal fields, which spread last week until about three-fifths of the 350,000 miners were involved, has been attended by considerable violence and a number of conflicts between the police and strikers. Several fatalities were reported. While the number of men on strike in the Westphalian district is now said to be decreasing, the movement has spread to other fields—notably Saxony and Hanover, and some twenty thousand men in these districts have gone out. At a meeting in Bochum, Mar. 19, the leaders of the miners' union decided to end the strike, as they now think it useless. Twenty thousand men have returned to work in the Westphalian region.

France

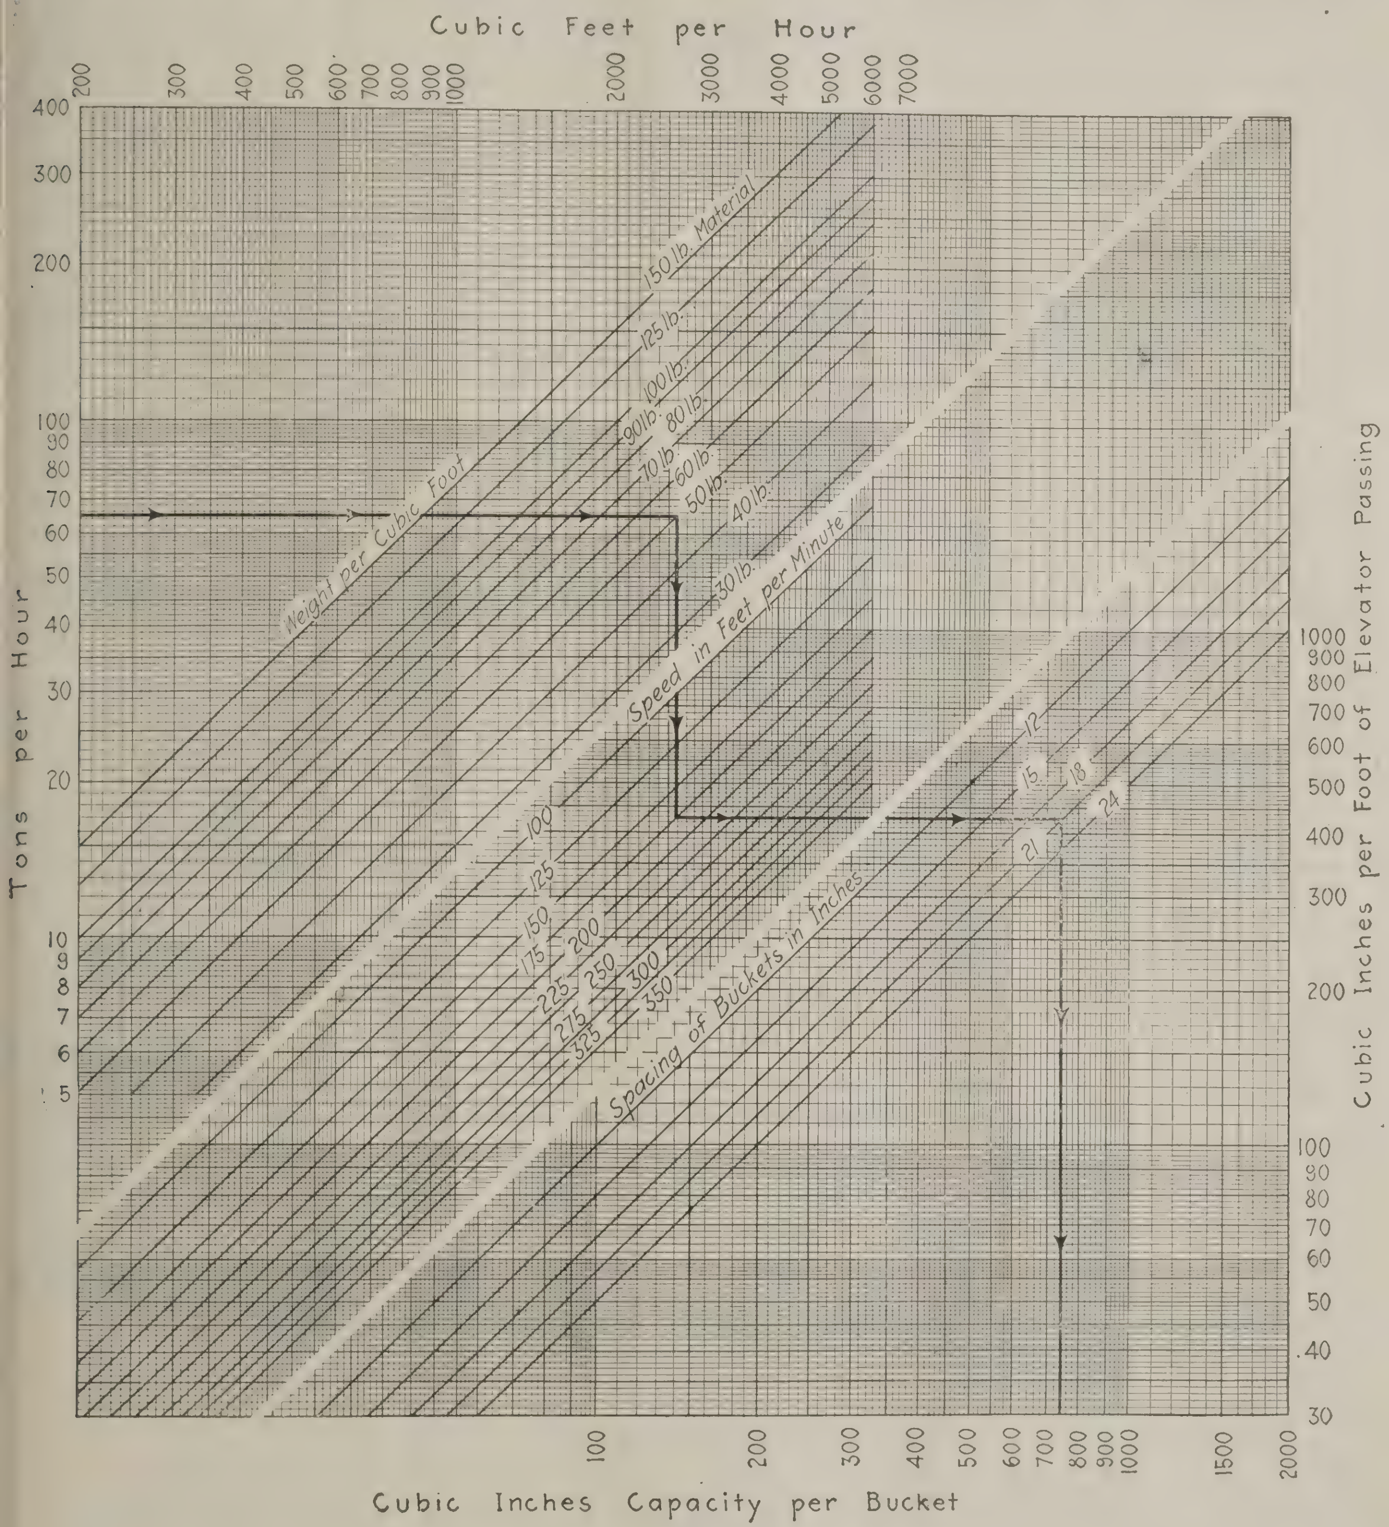
The strike, begun Mar. 18, in the region of Denain, is extending throughout the district and 7000 of the 13,000 miners have quit work. They demand an 8-hour day and a pension of 40c. a day at the conclusion of 25 years of service.

Bucket Elevator Chart

The accompanying chart shows at a glance, practically all the data necessary to determine the speed, capacity and size of bucket elevators, according to the practice of the Robins Conveying Belt Co., of New York. In using the table it should be borne in mind that the required bucket capacity found in the diagram is the working capacity, and somewhat larger buckets should be used, depending on conditions. It is common practice to assume the working capacities of Salem buckets as two-thirds to three-quarters of total capacity when they are operated on a vertical belt.

The heavy line gives the solution for 65 tons of coal per hour, at a speed of 175 ft. per min., and a spacing of 21 in., showing required working capacity of 740 cubic inches.

To find the horsepower required for driving a vertical bucket elevator, multiply tons per hour by lift in feet and divide by 500. This allows for 100% friction.



Capacity and Speed Chart for Bucket Elevators

To find the proper size of a bucket elevator for a given tonnage or volume of material per hour and given weight per cubic foot, enter chart at left with tons per hour and follow across to diagonal line showing weight per cubic foot, thence down the vertical line to diagonal line representing the desired speed of elevator, thence across to the right until the diagonal showing desired spacing of buckets is reached. At the bottom, vertically below this intersection, is found the required capacity of buckets in cubic inches. If the hourly capacity is given in cubic feet, enter at the top of the chart and follow down until the desired speed line is found, thence across to spacing, etc., as before.

Wire Rope Splicing

By F. L. Johnson

Wire rope is susceptible of almost perfect splicing and the operation is so simple that it may be learned in an hour by any mechanic who is at all skillful in the use of ordinary tools. For all kinds of transmission rope the long splice is used and should not be less than 16 ft. in length for ½-in. rope and increasing to 30 ft. for the larger sizes.

Where the splicing must be done in position, rope blocks are used to draw the wire rope taut, as in Fig. 1, care being taken to make fast far enough from the ends to leave plenty of room for the splice and the men who make it. If possible, it is better to hold the rope taut, mark the splice on both ends, by securely winding with No. 20 annealed-iron wire, throw it off the sheaves and make the splice on the floor or staging, as may be most convenient.

The strands of both ends are unlaid, back to the points wound with wire, the hemp core cut off and the ends of the rope brought together with the strands interlaced, as shown in Fig. 2. Any strand, as *a* (Fig 3), is now unlaid and closely followed by the corresponding strand 1 of the other end of the rope which is pressed closely into the groove left by the unlaid strand. The unwinding

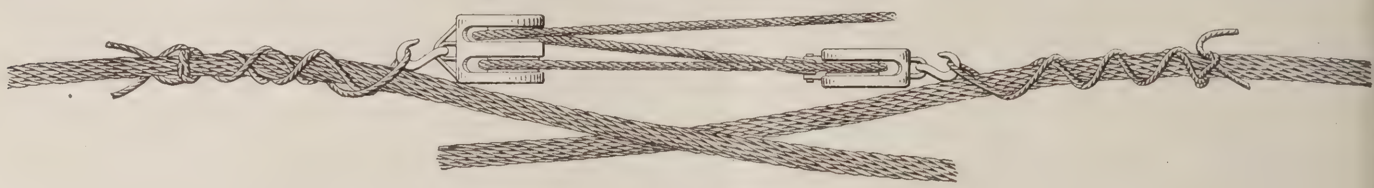


Fig.1.

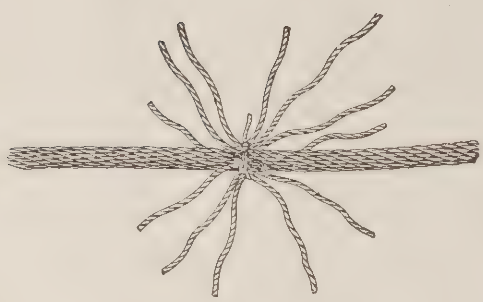

Fig.2.

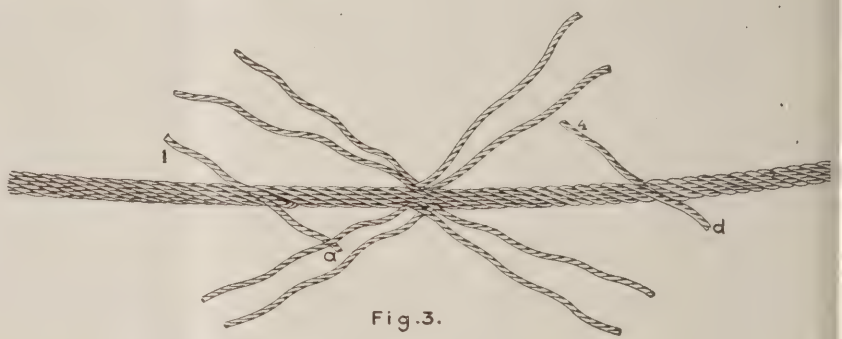

Fig.3.

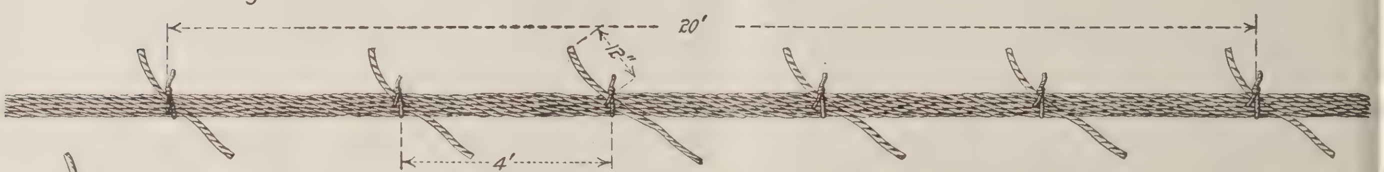

Fig.4.

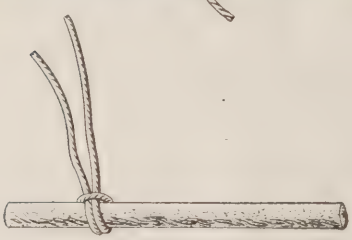

Fig.5

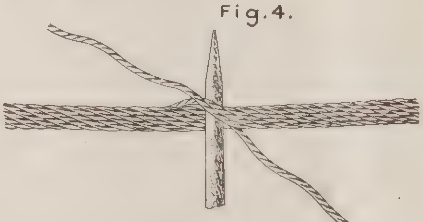

Fig.6.

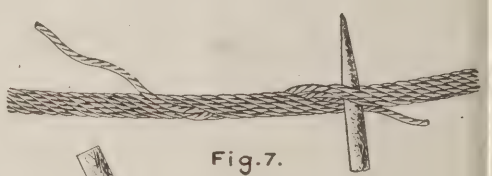

Fig.7.

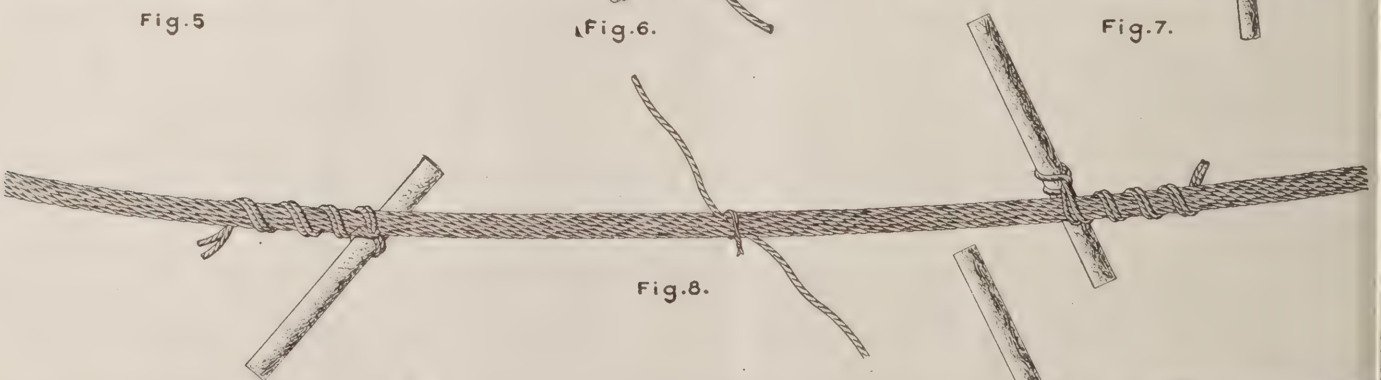

Fig.8.

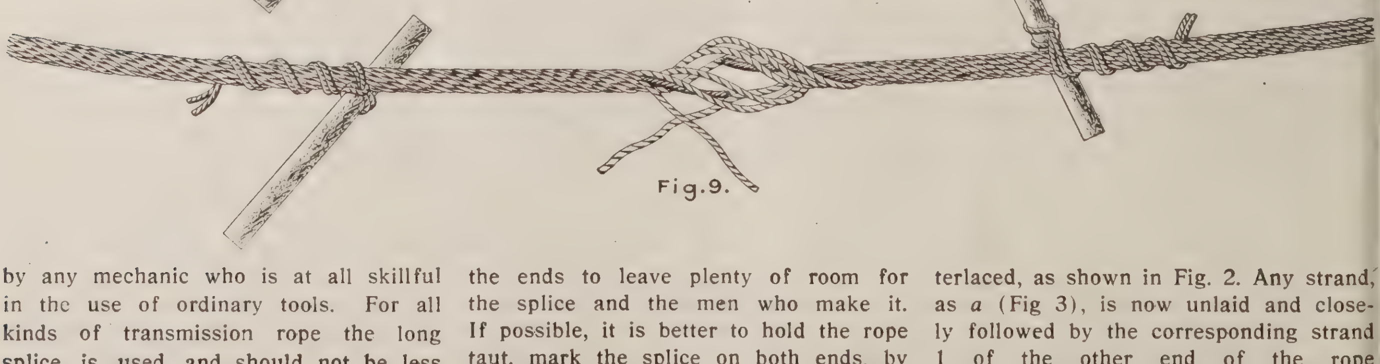

Fig.9.

Note—From "Power," Jan. 30, 1912.

of one strand and the inwinding of the other are continued until all but about 12 in. of strand 1 is laid in, when *a* is cut off at the same length and both strands securely tied with cord. Strands 4 and *d* are next treated in the same way and the process is repeated with each pair of strands until all are laid and cut, the projecting ends being tied to prevent unwinding, as shown in Fig. 4.

When this has been done the splice is bent and worked in all directions until the tension in all the strands is equal and the rope as flexible there as elsewhere. If this is not done and there is more tension in some of the strands than in others when a stress is put on the rope, these strands will pull into the rope, making a bad looking and weak splice.

Next, the open or free ends of the 12 strands are carefully trimmed and wound with fine wire. Two rope-and-stick clamps, Fig. 5, are now secured to the rope, one on each side of an end crossing, as in Fig. 8, for the purpose of untwisting the rope to allow tucking the strand ends into the middle of the rope.

There are two ways of tucking in these ends. They are first straightened with a mallet. The long ends of the rope-clamp handles are twisted in opposite directions, separating the strands and exposing the hemp core, which is cut off and pulled out between the points to where the tucked-in strands will reach and the ends forced into the place formerely occupied by the core.

This is most easily done with the aid of a marlin spike, which is passed over the strand that is to be tucked and under two strands of the rope, Fig. 6, and moved along the rope spirally following the lay and forcing the free end into the core space, Fig. 7.

In the other method the strands are more widely separated by untwisting the rope with the clamps, Fig. 9, slipping the free end in between the strands and correcting slight kinks by the use of a mallet.

The order in which the ends are tucked in is immaterial. Some operators prefer to tuck all the ends pointing in one direction before any of those pointing the opposite way, while others finish each pair of ends in series.

If the foregoing directions are intelligently followed the splice will be uniform with the rest of the rope, of nearly equal strength throughout, and after a few hours' use it will be almost impossible to detect the splice.

A New Type of Mine Humidifier

Special Correspondence

This humidifier raises the temperature of the intake so that the air is able to absorb large quantities of water. Steam is discharged into the air and the condensed water from both steam jets and radiator pipes is forced by a pump to pass in a fine spray into the air current.

The following is a report made by Wm. Nicholson and P. A. Grady, Mine Inspectors of the 11th and 12th districts respectively, to John Laing, Chief of the Department of Mines, W. Va.:—

"Pursuant to your instructions of Jan. 4, 1912, we made an examination of the apparatus for humidifying the air current as installed at the Powhatan Mine, and also a thorough inspection of the workings to determine the effect the humidifier had in rendering the air humid in every part of the area opened up.

Radiator, Atomizer and Vapor Jet Combined

The following is the result of our observations: The humidifier is placed about 700 feet in from the drift mouth and on the intake airway of the mine. It consists of a series of radiation pipes three inches in diameter running about 70 ft. in length. In all there are about 3000 lin. ft. of three-inch pipe running in five vertical rows with ten horizontal pipes to the row. The radiating surface of the whole system measures approximately 2250 sq.ft. The inside ends of the pipes are fitted with small steam cocks so as to permit the escape of some of the steam into the air current. The amount of the vapor thus escaping is based entirely on the amount of moisture needed by the air current of the mine in order that it may be kept at the desired humidity.

The condensed water which is formed within the radiator pipes is drained back into a concrete basin, from which it is picked up by a small pump and forced through German spray nozzles into the air current of the mine. The temperature of this water is from 85 to 90 deg. F. The condensed water from the escaping steam is also led back to this concrete basin and pumped into the air through the spray nozzles. The general result achieved is that the intake air current is raised above the temperature of the mine, thus enabling it to hold much more moisture, and a large quantity of water is deposited over the roof, bottom and sides when this current comes in contact with the cooler surfaces of the mine. Thus is effected a condition somewhat similar to that accompanying the high temperatures of the summer months. A large quantity of moisture is carried by the atmosphere during the summer and when the air enters the mines this moisture is deposited as dew as the heat is progressively abstracted.

Test Records

Before entering the mine, the thermometer reading on the outside showed a temperature of 21 deg. F. with a relative humidity reading of 100 per cent. With this outside reading there was entering the mine only 6.77 lb. or 0.818 gal. of moisture per minute in the air current.

After the air current had passed over the humidifier we obtained a reading of 73 deg. F. with a relative humidity of 65 per cent. The air current from this point on, carried 32.78 lb. of moisture per minute or 3.94 gal. showing that 26.01 lb. of moisture or 3.122 gal. was being injected and absorbed by the air current per minute.

A reading of 56 deg. F., relative humidity 100 per cent. was taken in the return airway near the fan. This showed that the total amount of moisture carried along in the air current at this point was 37.01 lb. per min. or 4.44 gal., indicating that 4.23 lb. or one-half gal. of natural moisture was being taken from the mine surfaces every minute.

The following readings were taken throughout the different sections of the mine, the fifth column recording the distance in feet traversed by the air from the humidifier to the point at which

HUMIDITY OBTAINED

BAROMETRIC PRESSURE AT TIME OF READING 28 INCHES

the reading is taken. In every case the coal dust was wet at the point at which observations were made.

The above table illustrates the actual effect produced on the air current where, as in this particular test, practically all the air circulating through the mine was passed over the humidifier and the whole area of the mine ventilated on one air current.

Wherever coal slack was found in the mine, it was always found to be in a moist condition, and when picked up in the hand was found damp and coherent.

Value of Humidifier

This agency for keeping a mine in a damp condition, we believe to be far superior to any of the other agencies in use, such as the water box and mule, the carrying of water to the different sections by means of pipes and hose, or the moistening of the air by means of steam. By keeping this apparatus in operation the superintendent is assured that moisture is being put into every part of his mine where the air current travels. The amount of moisture that is proper and necessary for the safety of the mine can be regulated and he does not have to depend wholly upon the human element. In using the obsolete water box and mule there is no assurance that the dusty section will be made wet and if water is put on dust in high and pitching places in a mine it quickly runs off leaving the section dry and dusty as before.

The severest winter conditions existed at the time our readings were taken, and there was shown to be 37,452 lb. or 4,496 gal. of water taken into the mine every 24 hours. To the practical operator it can be easily seen what the cost would be to put this amount of moisture into the mine with water boxes. The first cost of this apparatus is practically the only thing to be taken into consideration. The cost of maintaining and running it afterwards is a very small item. Only 52 boiler hp. was required in the operation of the apparatus at the time the examination was made.

Roof Should Be Kept Evenly Humid

The complaint is sometimes heard that heating the intake air of a mine by radiation or steam causes the roof to fall; this idea is erroneous for it is the varying difference in temperature of the air that causes the roof to contract and expand, thus making it fall.

In installing an apparatus of this kind to insure safe conditions within a mine from dust explosions, an operator can compute the boiler horsepower and the number of square feet of radiator pipe necessary, basing it on the amount of air entering the mine. A safety factor may be provided by assuming the lowest temperature and humidity conditions that may exist at any time during the year.

We think that Col. L. E. Tierney, of the Powhatan Coal & Coke Co. should be given due credit for the research he has made along this particular line.

A Remarkable Borehole

An interesting feat in horizontal boring has been carried out at the Middletown Colliery near Leeds, England, in drilling a hole 702 ft. long in a 4 ft. 6 in. seam of coal, which dips about one inch in five yards and has a 4-in. band of slate 22 in. from the top. The bore hole was driven 8 in. above the band, and throughout its whole length has been kept between the band and the top.

This can justly be considered a most remarkable accomplishment, and Fig. 1 shows the apparatus that was used to effect this result. The device is a safety hydraulic boring machine, made by George Burnside, of Shiney Row, Fence Houses, in the County of Durham, England, and probably offers the most expeditious method yet discovered for safely boring long holes in the vicinity of old mine workings in which dangerous gases and water have accumulated.

As may be seen from the illustration, the device is fitted with a stuffing-box and several valves or cocks. The tubular boring rods are made with flush joints and passed through the packed stuffing-box *L*, which maintains a water-tight joint during operation. When either water or gas is tapped, the full length of boring rods and drill is withdrawn through the stuffing-box until past the cock *S*. This valve *S* is then shut off and the drill point removed by unscrewing the cap of the stuffing-box. Thus, means are afforded for withdrawing the drill with perfect safety to the workmen and without chance of water or gas escaping.

After the boring rods are withdrawn, the water or gas may either be run off from the apparatus, or piped to some convenient point. A pressure gage mounted on the casing serves to indicate the pressure of the body of water or gas which has been tapped. It is, of course, necessary to keep the inside of the rods from becoming choked, and also to avoid any escape of water from the rods after holing is made; to this end the drill points are furnished with a spring valve.

The apparatus is made in four sizes, ranging from one to four inches in diameter of bore, and the record pressure that has so far been tapped successfully is 287 lb. per square inch.

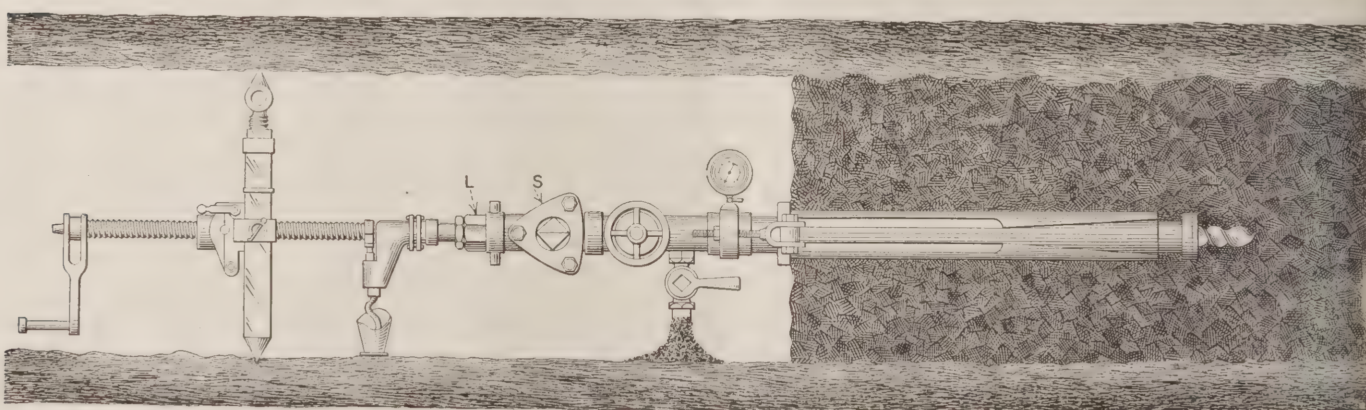

Fig. 1. Safety Hydraulic Boring Machine

Justification is found for the practice of storing coal in the open and spraying it in dry weather, in the conclusions reached by M. Mahler, who states that moist air has less effect upon coal than dry air. He found that under the influence of dry air at 25 to 30 deg. C., 150 grams of coal gave rise in 30 hours to 1 cu.cm. of carbon dioxide and 2.88 cu.cm. of carbon monoxide. At 100 deg. C. the gas produced was nine times as great and carbon dioxide predominated.

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Safety Catch for Cages

A South African exchange (Diamond Fields Advertiser) reports that the De Beers Consolidated Mines, Ltd., are interesting themselves in a safety catch, which was exhibited before the recent Safety Catch Commission, in Johannesburg, the members of which were so impressed with its simplicity and utility that they urged early tests under mining conditions.

The object of the invention is to provide an arrangement whereby in the event of breakage of the hoisting rope or wire the cage may be adjusted to stop within 12 to 60 ft. and be effectively supported. The apparatus is disposed at the upper end of the cage and comprises a rectangular frame, the side members of which are slotted to receive bearings in which are journaled two parallel shafts disposed on opposite sides of the wooden or metal guides and to each of which is keyed or fitted a pair of toothed wheels adapted to engage a face of the corresponding guide. Each pair of wheels is normally held, against the action of an adjustable spring, out of engagement with the corresponding guide by means of a wire, each wire being led round a pulley on a transverse of the frame and secured at one end to the corresponding shaft, the other wire being secured to the hoisting rope.

It is explained that the arrangement is such that when the hoisting rope is under tension the wheels are held clear of the guides, but in case the rope breaks with consequent slackening, the wires will also sag and permit the springs to press the shafts in the direction of the guides, so that the wheels engaging the guides are caused to rotate and to rotate the shafts. Each shaft has screw-threaded portions engaged by nuts, one incline face of each of which engages a wedge-shaped block, the blocks being fixed to the transverse members of the frame work. Thus by rotation of the shafts, the nuts are caused to mount the wedge-shaped blocks, and to force the shafts in the direction of the guides, causing the wheels to bite into them. The extent of rotation of the shafts is limited, according to the distance which the nuts may travel, so that when the cage has fallen slightly the shafts and the wheels will be gradually stopped by the jamming of the nuts, resulting finally in the suspension of the cage from the wheels.

Roof Action in Longwall Workings

Special Correspondence

The bending of the roof does not commence at the face line, but continues back over the coal. This is the reason why the coal breaks down along the mining face under the localized pressure. Chocks should not be set vertical but should be placed so as to lean two inches to the foot with their tops toward the working face.

In a paper entitled the "Action and Control of Differently Constituted Coal Roofs," read before the Midland Counties Institution of Mining Engineers, Mine Inspector W. H. Hepplewhite remarked that, with the statutory establishment of systematic timbering at all coal mines, it was thought by many that a remedy had at last been discovered, involving a great reduction in the number of accidents at the coal face. As a matter of fact, however, the expected diminution has not been attained, the death rate per 1000 workers by falls being 75 in 1910, as against 74 in each of the two preceding years. Probably, he added, when the workers become thoroughly disciplined into the necessity of strictly carrying out the timbering rules, better results may be obtained.

How Rock Breaks

A regular stratified shale of good vertical thickness directly overlying a coal bed, provides the condition favorable for the extraction of the coal and the safety of the workers engaged in the operation, for, if the line of longwall face is in a continuous straight line, the weight breaks will be found parallel to the coal face, or else the roof will bend back in the waste without any perceptible break.

If a true sandstone rock, which has no semblance of stratification or lamination, is many feet thick, the chances of extensive falls under normal conditions are rare. The weight breaks generally have a heavy back hade of about 45 deg., and the stone to guard against is in the form of wedge-shaped pieces from out of the open break.

In the event of the roof consisting partly of sandstone rock and partly of hard shale, without apparent stratification, it is apt to break at each successive web (or working face) along the line of the longwall workings. The break may be only faintly observable, or the roof may have bent a few inches below the seam of coal, this being most observable if the seam is of a hard texture and requires holing. Parallel breaks often occur a short distance apart and in between the regular face breaks. Where the holed coal, when taken down, extends over the solid for a short distance, the roof between the sets of bars is often a source of danger to the loaders of the coal, and should be timbered in advance of them.

An Independent Roof Unit

The form of roof known as "non-stratified clod" occurs usually where a thin seam lies above the one worked, and the thicker the clod is, the less difficulty is experienced in safely supporting it. The thin seam rarely gives any adhesiveness to the clod, which falls away without any warning, such as other forms of roof often give.

A bed of shale, of the weakness of clod, overlying a seam, is another specially dangerous form, and when once the roof has broken there is no knowing where the cleavage will end.

Mr. Hepplewhite says that irregular bedding most often occurs where the roof proper overlying the coal bed is a tenacious rock stratum a few feet thick, and adds. The "intrusive shale" (if we may be permitted to use such a term for rock older than the stratum which covers it), from whichever side it is approached by the longwall face, begins with a thin edge immediately over the coal. It gradually grows thicker, until it has attained several yards in thickness, and as the coal face advances it gradually runs out exactly as it began. When it is considered that the "intrusion" has a diameter of several hundred yards, it will be obvious that a long time must elapse in order to work a face of longwall work across it. It is when working under the thin edges that the greatest danger exists from detached pieces of stone. The

loose roof is shaped like a cantilever and does not have sufficient strength to be self-sustaining; moreover, any little irregularity in thickness makes the cross-section inadequate.

Bad Roof and Care Copulate

The inspector says it is commonly supposed that accidents occur most frequently where the roof is worst, because detached pieces are liable to fall, but such is certainly not the case. The fact that the workmen are fully aware of the bad condition of the roof makes them exercise every care in using plenty of supports. Accidents are more likely to occur and usually happen, where the roof is comparatively hard. Risks are therefore run, and when an accident results the usual exclamation is: "Who would have thought it?" It is a well established fact that the greatest number of accidents occur from local detached pieces of roof stone. The fatalities from large falls are only of rare occurrence at the coal face. If accidents are scarce where a bad condition of roof prevails, surely by the same analogy they ought to be scarcer with comparatively good roofs. It seems to Mr. Hepplewhite that if the same precautions were exercised with regard to the method of timbering in good and bad roofs alike, discipline among the workers and sweet reasonableness all round ought to reduce the number of accidents to a minimum.

Regularity of Jointing

Discussing the line of cleavage, it is pointed out that it never varies. When once the working face has been started at whatever angle to the cleavage, that angle between working face and cleavage may be depended on never to alter. Proceeding, Mr. Hepplewhite says the worker knows by advancing the mining face directly parallel to the cleavage (face on) that he has little labor to exert in extracting the coal. The roof action is continuous along a line of face, and for several feet it rides over the coal. The line of least resistance is on the coal itself, which pushes off and prevents fractures from occurring in the roof. It will bend back toward the waste with a depression of about 2 in. to the yard. The pressure may occasionally defeat itself, and instead of always advancing over the solid coal there may be an extra weight sufficient to cause the roof to fracture along the face line. The consequence is that the coal has been relieved of its pressure and becomes set and tough. The coal will have to be advanced several yards before there is sufficient weight on it to enable it to regain its normal condition. The fracture produced by the extra weight is usually semi-arched, with a smooth surface, as the result of friction. As regards roof depression, it is of little importance at what angle of the cleavage the coal is worked, because the support has been removed, and the same amount of subsidence will be the result; but the control of it has a material effect.

Mr. Hepplewhite says the chief function of the roof supports in longwall working is to prevent the roof stratum, especially local detached pieces, from causing injuries to the workmen. No method of roof supports ever yet introduced could sustain the roof stratum in its rigid condition. When once the coal support is taken away subsidence is bound to follow in due course. The subsidence under normal conditions is slow in action, and imperceptible to the workman. He is only aware of the roof settling from the fact of each line of fracture becoming more open, the roof depressed, and a renewal of broken timbers being required. The complete settling of the roof stratum up to the surface depends on the depths and the tenacity of some of the upper measures.

Packwalls Should Be Battered

On the question of packwalls the inspector says it is a mistake to build them vertically, because it is obvious that the lateral pressure has a great tendency to push them inward before the vertical pressure has tightened its hold. A good principle is to build the packwalls with a batter of about 6 in. in the yard. A 4½-ft. bed should be packed on a batter of 9 in. and a 6-ft. bed on a batter of 1 ft. It would be found with the pressures acting conjointly that the packwalls would assume the solidifying state without bulging.

An ideal way to construct a packwall would be to build the first half, no matter how thick the seam, with a batter of 9 in. and the remainder vertical. As the lateral pressure proceeds, the packs would all be pushed to the vertical line and remain to take the top weight.

Workmen are generally instructed to commence building packs on the bare floor at the sides of the roadways, but Mr. Hepplewhite says he has come to the conclusion that both for safety and economic purposes it is a big mistake to build them in that manner.

Electric Hoisting in Upper Silesia

Special Correspondence

Electric hoisting plants, particularly those of the Ilgner system, are being largely adopted in this region. One unique installation has the hoisting motor directly connected to a turbogenerator.

Note—From paper read at meeting of the North of England Institute of Mining and Mechanical Engineers, by Henry M. Hudspeth.

Electric hoisting for main shafts is being largely adopted in Upper Silesia, and the Ilgner system appears to be mostly favored. Electric winding is particularly well adapted to working inclined seams where, owing to the continually increasing depths, it is often a considerable time before the output from a fixed level reaches its maximum. The electric hoist easily lends itself to enlargement, for the Koepe pulley or drum can be coupled to one motor, and provision made for the subsequent addition of a second motor; the Ilgner system especially lends itself to development in this direction, as the flywheel-converter plan can be arranged to suit varying demands.

In certain instances it has been necessary to erect the winding machine on the headgear, as at the Deutschland mine, where there was no room for the hoisting-engine house on the ground level. At that mine the Ilgner system was adopted, the main particulars of the plan being as follows:

The motor-generator takes three-phase alternating current at 3000 volts, and when running at 470 r.p.m. gives 444 h.p., the weight of the flywheel being about 17¾ tons. The winding motor, which takes direct current at 600 volts, has a maximum capacity of about 620 h.p., when running at a maximum speed, or 63 r.p.m. The Koepe pulley is 14¾ ft. in diameter, the depth of wind 780 ft., and the maximum winding velocity 35 ft. per second. The weight of coal per wind is 2½ tons and the amount drawn per 10-hour day is 690 tons.

Economic Advantage of Electric Hoist

The greatest economical advantage of the electric hoist is its low steam consumption per shaft-horsepower-hour, which moreover is the only real basis of comparison that can be made between electric and steam winders. The cost per ton hoisted is certainly a most important item, but it forms no basis of comparison unless two plants happen to be identical, which is rarely the case. Again, the steam consumption of an electric winder is a predetermined and practically unalterable quantity. In the case of steam winders the steam consumption depends to some extent upon the operator. Electric hoisting engines are considered safer than steam hoists, as evidenced by the fact that in Upper Silesia a

speed of 33 ft. per sec. is allowed for hoisting men with an electric machine, as against 20 ft. with a steam machine, an important consideration, especially in the case of deep mines.

At Castellengo colliery the two winding engines are constructed on the Siemens-'Ilgner system. The main particulars are:

Depth of shaft in feet	853
Useful load in tons	2.26
Cage, number of decks	2
Cage, cars per deck	2
Cage, weight in tons	3.25
Velocity of hoist, in feet per second	41
Diameter of winding rope in inches	1.49

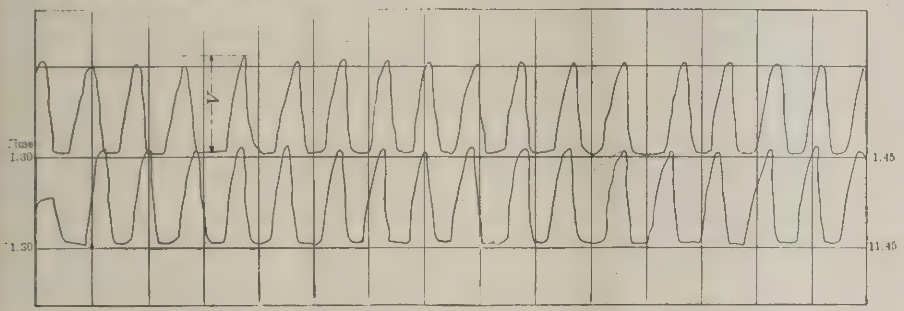

Diagram Shows How Quickly Full Speed Is Reached

The speed curves of the winding motor for part of an ordinary day's work are shown in the accompanying diagram. Mr. Hudspeth explains that the load on the winder changes over from —74 to +790 h.p.; for balancing the same the flywheel is 13¾ tons in weight and when running without load it has a peripheral velocity of nearly 325 ft. per sec. The balancing of the load by the flywheel is brought about as follows: If the load on the winder exceeds the normal, the excess must be taken from the flywheel, this being accomplished by inserting a resistance in the rotor circuit of the three-phase motor, the revolutions thereby being decreased and energy taken out of the flywheel. On the other hand, should the load be less than the normal, the resistance is cut out and the motor winding motor to be run only at a decreased velocity. The flywheel may thus be again run up to full speed when the interruption of the steering lever is cut out.

Winder Made 82 Hoists per Hour

Under test the winder made nearly 82 hoists in an hour, corresponding to 44 sec. per hoist, distributed approximately as follows: Period of acceleration, 12 sec.; period of maximum velocity, 10 sec.; period of retardation, 14 sec.; period of dumping, 8 sec., total time, 44 seconds.

So far as Mr. Hudspeth is aware, the electric-hoisting plant at the Heinitz mine is the only one in existence in which the winding motor is directly connected up to a turbo-generator. He gives the following brief description of the plant:

A Brown-Boveri-Parsons high-pressure turbine is directly coupled to a direct-current generator and an alternating-current generator. The three-phase alternating-current machine supplies electricity for the general working of the mine and the braking of the hoisting motor is made to furnish electric energy. The direct-current generator is connected up to the winding motor by means of the Ward-Leonard control.

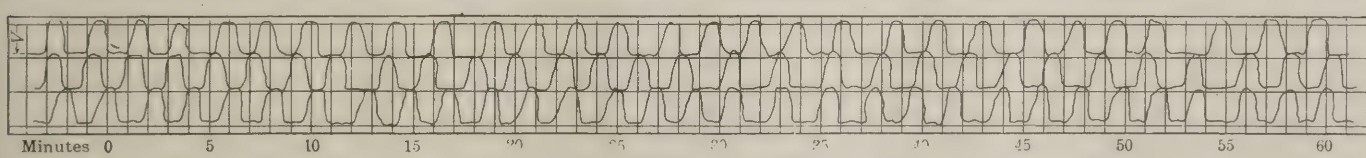
turbine is of special interest, inasmuch as it is the means by which the turbine is enabled to take the heavy starting load of the winder. The valve operates in the following way: Under normal load the steam is throttled at the turbine inlet, so that the pressure behind the admission valve is the same as that before it, the automatic overload valve then steps into operation, and live steam is admitted to the second expansion step of the turbine, thereby increasing the capacity of the turbine considerably.

Advantages of the Overload Valve

The percentage of vacuum in the condensing plant affects to a certain extent the working of the overload valve. If the condensing plant is heavily loaded, the starting of the hoist brings the overload valve into operation sooner than usual; on the other hand, when the vacuum is good the overload valve is at times not opened. A further advantage of the automatic valve lies in the fact that if the boiler pressure sinks, the valve comes sooner into operation and so keeps the turbine up to its required capacity.

The speed of the turbine is altered by starting the hoist, but not to a dangerous extent. The revolutions per minute undergo an alteration of less than 2 per cent. (from 1490 to 1505) when the load due to the winding motor changes over from the greatest positive to the greatest negative value. This alteration is so small that it is not sufficient to bring the three-phase generator out of step.

The author explains that the hoisting apparatus proper consists of a direct-current motor coupled direct to a Koepe pulley, provision having been made for the addition of a second similar motor. The machine has the usual retarding and safety devices, the safety brake being put into operation and the main switch opened when, (1) the exciting current for the motor fails, (2) the existing current



Hoisting Diagram Showing Time Consumed in Hoisting

runs the flywheel up to its full speed. The actuation of the resistances follows automatically. The over or under loading of the converter necessitates a stronger or weaker current from the three-phase mains, which increase or decrease of the current, sets into operation a small motor in a direction corresponding to over or underload.

If the energy of the flywheel is drawn upon to such an extent that there is not enough resistance to balance, which may happen if both winding engines commence together, the steering lever is automatically prevented from being set out as far as usual, and this allows the

Following are the main particulars of the hoisting plant when finally completed:

Depth of shaft in feet	2526
Coal per hoist in tons	7
Velocity of hoist in feet per second	32.8
Tons per hour	226.4
Diameter of Koepe pulley in feet	26.25
Cage, number of decks	4
Cage, number of cars per deck	3
Diameter of winding rope in inches	2 9/16

Mr. Hudspeth proceeds to say that the turbine, which has a maximum output of 1740 kw., takes steam at 140 lb. per sq.in. (superheated to 527 deg. F.), and is connected to the central condensing plant at the colliery, which shows on an average a vacuum of 92 per cent. The patent automatic overload valve fitted to the

increases to 15 per cent. above the normal; that is, by the inadmissible increasing of the turbine revolutions, or (3) by the rotor current increasing above a fixed maximum through an excessive load on the motor. The motor is built for a continuous output of 557 h.p. at a speed of 24 r.p.m. per min.; its maximum output, however, is 1346 h.p. The field excitation is at 110 volts and the armature receives current at 490 volts.

The figures herewith reproduced from sketches submitted with the paper show the speed curves for the winders at the Castellengo colliery and Heinitz mine respectively.

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

The present controversy between coal operators and miners is filled with uncertainties, but none are of greater consequence than the doubt concerning the character and caliber of John P. White, president of the United Mine Workers of America.

This man, born at Coal Valley, Ill., in 1870, started life as a trapper boy in the mines when only 13 years of age. After working 16 years underground, part of the time driving mules and the remainder of the time mining coal, his associates in Iowa (where he had afterward settled) chose him to be secretary and treasurer of the miners' organization in that state.

It didn't take young White long to prove that he had executive ability as well as a likable manner, for when he took hold of the union finances in Iowa, there was just $600 in the treasury. After serving the miners six years, "John P." left them with $500,000 in the bank.

In the politics of the national organization, Mr. White does not lack experience. He was called from the presidency of the Iowa miners to act as vice-president of the main organization. After serving in that capacity a year, he was again returned to the presidency of the union in Iowa, filling the position for another two years. This work was followed by his election to the highest office in the national union, succeeding Tom Lewis as president.

Coal people, and to some extent, the public, have now fixed their attention on John White. This is his first big fight and the vantage points on the field of battle are occupied largely by the artillery of the enemy. It is also a fact that general industrial conditions are somewhat adverse to his cause.

At a critical time like this, however, labor forces become fairly united and recent months have witnessed the addition of many names to the United Mine Workers' roll of membership. Furthermore, for each union miner who ceases work, it is safe to figure that one other man not a member, but only a follower and sympathizer, will lay down his tools. It's this condition that makes it possible to call out 80 per cent. of the men when only 40 per cent. may be members in good standing.

There is no doubt but that John White has a preponderance of that essential quality, caution. It is also true that his frankness and evident simplicity will prove the one surprise and perhaps the

John P. White

undoing of many opponents. He fully understands that "the surest way to convey misinformation is to tell the strict truth," and you are likely to leave him, after a conversation, believing he has laid his whole hand on the table, when some of his best cards are in his shoe or up his sleeve—always handy, but quite invisible.

Two of the clubs that "John P." has grasped and will wield with maximum effect are, first, the general fuel deficiency that exists, and which, because of labor troubles abroad, is international in scope; second, the effect of a general suspension of mining on the political situation in a presidential year.

When I suggested to Mr. White that the railroads of the country have been buying and storing thousands of tons of coal, he replied with positiveness that such was not the case, and pointed to certain roads (all Western) where no surplus had been laid by. I mentioned that, although the big anthracite companies did not have their storage yards filled to capacity, they had a normal supply on hand, and that one condition prevailed now that was not the case when the last big strike occurred in 1902: Today the people, remembering conditions that existed during the trouble 10 years ago, have filled their cellars and a great amount of coal has thus been stored. The increase of nearly a million tons in the February output of anthracite was absorbed in this way.

One thing is sure, John White believes he has not underrated the strength of his opposition. A remark I made caused him to lean forward and say, "I know they're strong and I fully realize that the anthracite operators are better fortified today, financially and otherwise, than ever before, but we also are in much better shape than most people believe." The seriousness with which this statement was delivered convinced me that the union leader is fully aware of the great responsibilities resting on him, and that, if he enters a conflict, the dire possibilities to his followers will have been carefully weighed.

White's head is broad, his jaws square and every feature indicates determination. He is not the aggressive type of man however, and it's probable his fights will be conducted without any flare of trumpets, and with an absence of red fire. It's this quiet inherent strength of the man, coupled with his serious view and intelligent understanding of the far-reaching effect of his decisions, that makes him a puzzle as well as a danger to his opponents.

His views on vital questions affecting the mine workers are positive and clear. He does not believe that it is necessary for a union to be incorporated, so that both parties to a labor contract are equally liable. As to the anthracite conciliation board, Mr. White is ready to acknowledge that this commission has accomplished some good, but says there is such a long delay before a man can get action that the value and efficiency of the board are destroyed. I also inferred that he is of the opinion that men are reluctant to carry a dispute to the conciliation court, because of the bad light the man is placed in in the eyes of his employers.

When I spoke of the "check off" system the miners are demanding of the anthracite operators, Mr. White indicated plainly that he considers this demand, not only fair, but absolutely essential to the successful growth of the union in the Pennsylvania field. He may have been bluffing, but his expressed ideas on the matter and his evident determination to back up his opinions, seemed real. If this should prove true, then we are facing a storm in the anthracite field that will make the strike of 1912 appear like a summer zephyr.

COAL AGE

Anthracite Operators Stand Pat

After a session lasting only 23 min., the third, and, for the present, the final joint conference of the anthracite miners and operators adjourned *sine die*. President White, of the miners, read their formal acknowledgement of the operators' refusal to grant their demands and concluded with a few remarks, expressing regret that their plea was disregarded. The chairman of the meeting, Mr. Baer, then declared a motion to adjourn was in order. This motion was made and carried.

Those familiar with the mechanism of "fixing a scale" will doubtless welcome the end of these usual (and useless) preliminaries. The customary ultimatums have been made by each side, the usual recriminations, charges and countercharges exchanged, and the public may now rightfully expect the contending principals to get down to business.

An analysis of the issues involved in the present controversy discloses no new features. The miners' initial demands for wage increases, amounting to 40 cents on the ton, above the present scale and aggregating 28 million dollars annually, or approximately one-sixth the total value of the anthracite production are, of course, absurd. On the other hand, their plea for an advance on the grounds of the increased cost of living appears to be well taken. In compensation for this the operators quote the bonus accruing to the miners through the workings of the sliding scale, which averages three million dollars per annum, and show further that the average working time of the miner has increased 28 per cent.

Of other points in contention, probably the most serious is the "check-off." The operators regard this with uncompromising disfavor, and will fight to the last ditch before conceding such a principle. On the other hand, the miners appreciate that the very life of their organization is dependent upon it and will, accordingly, demand its adoption just as vigorously. If, as the operators claim, the statutes of Pennsylvania prohibit the check-off, the miners should show some satisfactory method of overcoming this or exclude the measure from their demands.

Dustless Mines

The experiments at Bruceton and Pittsburg have probably produced a benumbing sense that dust removal cannot be made sufficiently complete to produce immunity from coal-dust explosions. Small bodies of dust, smaller perhaps than are contained per foot run of gangway and room in any operating mine, have produced most severe effects, actually lifting the surface material at Bruceton by which the mine was covered. It is convincing, but by no means consoling, to remember that these effects of small quantities of dust could be and had been forecasted from a knowledge of chemistry. So it is clear that theory and practice both require *absolute* dustlessness in a mine if from dust removal any good results are to be expected.

Some years ago a mine in West Virginia had a severe explosion. It was thought that the disaster was caused by dust. The dust was removed, but soon after another explosion occurred, and some were of the opinion that this recurrence of the event, after the alleged cause was removed, showed that the original diagnosis was entirely mistaken.

But was it? A body of men, as Mr. Blackett has shown, in an address before the North of England branch of the British Association of Colliery Managers, enters a mine with shovels and brooms. They fill carload after carload with dust, and it is drawn out of the mine. The workings then appear safe, but the finer and probably the newer dust flies away in the air current and finds new resting places; moreover, the fuel content becomes exactly equal to the needs of the oxygen present in the air. Such conditions favor the most complete and violent dust ignition.

The result is easy to imagine. The dangerous coal particles are still present

in a proportion most favorable to aid an explosion. The less dangerous particles alone have been taken away and what little stone dust is naturally to be found in the mine is removed. The more we consider dust removal, the more forcibly it is borne home that mere dust collection is not a panacea for colliery explosions, especially if the method adopted is not one in which suction takes a leading part. A vacuum cleaner may remove just that part of the dust from which most is to be feared, but the brush-and-shovel gang do but make conditions worse rather than better, and, in fact, it would seem that the operation of dust collection as at present conducted is fraught with much danger to those engaged in it.

It is considerations such as these which lead us to emphasize the importance of humidification, schistification and other cures. They do not demand the impossible. A mine *can* be made so damp that all the coal dust will be moistened whether resting or flying. The air can be made so humid that several calories of the heat of combustion can be absorbed by the water vapor it carries. A sufficient body of flue dust or ground-rock dust can be put in the mine to dampen the heat of an explosion. Taffanel barriers can be erected, which will make the extension of an explosion well nigh impossible. Watteyne's external tamping can be used to deaden the escaping flames from blown-out shots. Permissive explosives can be used to reduce the possibility of a primary ignition.

But no man who has experience in mining will advocate the keeping of an absolutely clean mine. The funds of no coal company are large enough to prevent an explodable amount of coal dust being in almost every room and entry from the pit bottom to the remotest recesses of the workings. It is not, however, too severe a requirement to demand three things: Firstly, that the deposit of dust from coal of *recent* mining shall not be large; secondly, that none of the dust, recent or aged, shall be dry, and thirdly, that side by side with all the coal dust shall be a foreign dust or powdered material capable of withdrawing heat from what dust may burn, extinguishing it thereby, as the enveloping gauze of a safety-lamp restrains the flame from entering the surrounding air.

With all our experimentation we are yet without much needed information. We do not know the relative explosibility of old and new dusts; we do not know what are the requisite qualifications of a schistifying powder. It has not been proved but rather assumed that the coal dust just formed is more dangerous than the old, and it has not been shown just how far the dehydration and decarbonization of dusts intensify their power of controlling an explosion.

Powder in the Mines

The dangers arising from the presence of powder in the mines have been generally thought to result from its careless handling, but it should be remembered that one of the principal dangers to be apprehended is that of detonation during storage. The laws of some states limit the amount of powder which may be carried into the mine by an individual miner. As a rule, in such states not more than five pounds or not more than is sufficient for one day's work may be taken by the miner to his working face. Probably those who incorporated the provision in our state laws overlooked one important merit in this requirement.

Prior to the enactments, the miners left large quantities of explosives in the mines at night. Often for safety they would hide these in the gob. If a fall of rock took place over the miner's powder chest or over the place where he had hidden his powder, a widespread explosion might result for the small burst of violence from the contents of the keg might be augmented by the added force of exploding gas or dust. It must, however, be here remarked that this could not have frequently occurred, for we do not remember in a long course of years a case where a powder keg was found detonated by a rock fall. Some explosions may have had that origin and not been charged to the right causes. The two explosions at Adrian have been ascribed to rock falling on powder; perhaps those at Bellevue in Canada may have had such a source and in Wales the Maindy and Pentre explosions may have had a similar origin.

A provision regarding the carrying of all powder out of the mines on quitting work should be made and strictly enforced and the requirement that only sufficient powder should be taken into the mine for one day's work should be unfalteringly observed, among other reasons for the purpose of backing up the provision just proposed. For, if a miner carries but little powder into the mine, he will almost inevitably carry out his canister at the end of the day for replenishment.

Despite all that has been rumored, it will be seen from the report of the Bureau of Mines that all permissibles are capable of detonation. Under favorable conditions almost any mine explosive can be made to explode by means of a blow. It is well known that a rapid glancing blow from a broomstick will ignite powder and for a long time this primitive test was used to prove the relative safety of explosives.

Detonable bodies should always be stored under good roof and the ground around should be freed from fine coal dust. They should not be left where gas is likely to be found in unsafe percentage, and Dr. Thornton has shown that even when the gas is in itself not sufficient to constitute a menace, dust and gas may combine to cause an explosion with greater facility than dust alone.

Government Ownership of Coal Lands

The acquisition of the brown-coal lands of the Leipzig district, Germany, is said by Vice-Consul W. W. Brunswick, of Chemnitz, to be a step in the gradual move of the government to own and operate all coal lands in the kingdom of Saxony. This is an important economic measure, as the plan of the German government to keep such lands in reserve will insure the preservation of a large coal territory for future generations and assure the working of the fields in a regular and systematic manner. The acquisition of an extensive area at Kieritzsch will be considered by the Saxon parliament at its next session.

The mine laws of New South Wales state that no person will be allowed to act as a mine electrician or as an assistant electrician, unless he shall be the holder of a certificate of competency, issued by the Department of Mines, authorizing him to act in either of these capacities. Mine engineers also are examined by the government and only the holders of certificates may be employed where life is at stake. It would be well if mine laws in the United States made like provision.

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Electric Pump in Mine

On page 685 of COAL AGE, Mar. 2, T. E. Richards states he has an electric pump located 1200 ft. from the water in a mine and discharging 2000 ft. to the surface, using 2-in. suction and column pipes. Mr. Richards asks if it would be wise to use a 3-in. pipe line instead of the 2-in. now installed, and to set the pump nearer the water.

I would say that with a long suction pipe, or one with bends and valves, the resistance to the flow of water to the pump will be considerable. In any case, with such a long suction pipe an air chamber should be used, in order to maintain a continuous flow of water to the pump and avoid the necessity of stopping this flow at each stroke of the pump. The resistance caused by the long suction pipe may be so great that the atmospheric pressure acting on the water may not be sufficient to force it to the pump, especially if the vertical height or lift is considerable. When the pump is set right over the water basin, the pump will work better, generally, if the lift does not exceed 18 ft. A pump always works better when located near the source of the water supply; but when the pump is located at a distance from the water and the suction pipe has a long horizontal run the pipe line should be one or two sizes larger than is required where the pump is located near the water. When there is no air chamber on the suction pipe, the water flowing through the pump comes to rest at each stroke of the pump; and when the suction pipe is long and the resistance great the water often does not flow to the pump as rapidly as the piston moves. This causes an imperfect action of the pump and produces a severe blow called "water-hammer" or "pounding" when the piston again meets the inflowing water.

In determining the size of pipe to be used in pumping it is customary to assume a velocity of 400 ft. per minute in the discharge pipe, and half this velocity or 200 ft. per minute in the suction pipe.

Now assuming the 2-in. column pipe is used, as at present installed, and calculating the volume of water discharged in feet per minute, for a pipe 2 in. in diameter and a velocity of 400 ft. per minute, or 6.6 ft. per second, the volume of water discharged (G) will be

$$G = 2.448\ d^2\ v$$

$$G = 2.448 \times 2^2 \times 6.6 = 64.62, \text{ say } 65$$

gal. per min.

The formulas for calculating the diameters of the suction and discharge pipes, when the flow of water is given in gallons per minute (G), are as follows:

Discharge pipe,

$$d = 0.25 \sqrt{G} = 0.25 \sqrt{65} = 2.1, \text{ say } 2\ in.$$

Suction pipe,

$$d = 0.35 \sqrt{G} = 0.35 \sqrt{65} = 2.8, \text{ say } 3\ in.$$

I would place this pump nearer the source of water supply, say moving it down about 1000 ft. This will give the pump 200 ft. of a suction line and 3000 ft. of a discharge line.

ARTHUR DUKES,
Mine Foreman.

Marsteller, Penn.

Thawing Frozen Pipe Line by Electricity

I have been much interested in the question asked by "C. B." and answered in COAL AGE, Feb. 10, p. 586. The question asks how can electric power be used to thaw out 100 ft. of a frozen 2-in. iron pipe line; and what arrangements are necessary in order to accomplish this. The question states that ample electrical power is at hand, but does not say whether the current is alternating current or direct current.

If direct current is being used, which is generally the case in mining practice, a motor-generator is necessary in order to reduce the voltage of the current to, say 30 or 40 volts, and obtain a current of from 300 to 400 amp. On the other hand, if alternating current is being used, the arrangements that are necessary to transform the current are entirely different. A special transformer would then be required to regulate the voltage to the desired amount, and to give the proper amperage. Either of these methods is probably an economical one to employ, if the power consumption is the chief factor to be considered.

I would like to ask, however, if a water resistance could not be used with direct current, where there was a pressure of, say 250 volts and a current of 1500 amp. Would it not be possible, by the use of a water resistance, to reduce this current to the proper voltage and amperage for thawing the pipe line?

Suppose, for example, that it required 300 amp. at 50 volts pressure to thaw out the pipe line, what would be the effect on the pipe if there was 150 volts pressure, and 300 amp. flowing through the pipe? Would this additional pressure or voltage have any effect on the heating capacity of the current? I appreciate the fact that this would be a wasteful method if it could be employed. I wish that some of our readers who have had experience in thawing pipe lines by means of electricity, and who understand the use of the different electrical currents, would give us their experience and advice.

THOMAS BRENNAN.

Herminie, Penn.

[The water resistance suggested by our correspondent is a very convenient form of rheostat and can be employed to step down the voltage the desired amount. What pressure will be required to give the current necessary to heat the pipe will depend on the resistance, which can only be determined by trial or test. The heating effect is determined by (I^2R) the square of the current times the resistance. If the resistance of this pipe is such as to allow a current of only 300 amp. to pass under a pressure of 50 volts, the remaining 100 volts will be lost in the rheostat and wasted.—EDITOR.]

The Proper Size of Pipe

Replying to the question of T. E. Richards, in COAL AGE, Vol. 1, page 685, regarding the proper location for a pump and the best size of pipe to use, I note that he leaves out two important factors: The capacity of his pump and the amount of water to be discharged in a given time. These would determine definitely the advantages to be gained by making a change. Since he says nothing about pumping against a head, I am assuming that the suction and discharge are practically level.

As is well known, the practical lift of the ordinary pump will not exceed 24 ft. Referring, then, to a table giving the loss of head in pipes for each 100 ft. in length, we find that a flow of 3½ cu.ft. per min. through a 2-in. pipe will cause a loss of head, due to friction, of practically 2 ft. per 100 ft. of pipe. The suction in this case is 1200 ft. in length, so that the loss of head due to friction would be 24 ft., or the maximum limit of suction.

Assuming that this pump is large enough to handle twice this amount of water in the same time, a change to 3-in. pipe on the suction would reduce the loss of head due to friction in the pipe to 1 ft. per 100 ft. of pipe. Under these conditions the loss of head in the suction pipe, due to friction, would be equal to

12 ft. when handling a flow of 7 cu.ft. per min. This allows him to pump the same amount of water in 12 hr. that now takes 24, and the work required at the suction end of the pump would be only half as great.

For the discharge end we find by reference to the tables, that by doubling the rate of flow as stated, there is a loss of head, due to friction, of a trifle over 7 ft. per 100 ft. when using 2-in. pipe. This amounts to a total of 140 ft., which is about the limit of the ordinary low-pressure pump. I would recommend for use in this case a 2½-in. pipe which would give a friction head of about 46 ft. It is generally a good rule in all pump installations to make the suction at least 50 per cent. larger than the discharge.

W. D. GRIFFITH,
Civil and Mining Engineer.
Pikeville, Ky.

Mine Pump Problem

In reply to Mr. Richard's mine-pump problem contained in your issue of Mar. 2, I would recommend him to lay the 3-in. line, which he has on hand, and to move the pump, providing there is lodgment enough for water. I would also have a 4-in. suction and a 3-in. discharge. I think 12 hours or less would suffice to remove the water if the pumps were located nearer the sump. It makes it easier for the pump to continue primed, and also easier to start the water after it has been stopped. By this arrangement you can pump 2⅛ times as much water as before, with a consequent reduction of attendance and of power used; moreover a saving of wear and tear in the line will be effected.

Marion, Ill. DAVID FULTON.

[Mr. Fulton's suggestions are good, but he overlooks the fact that Mr. Richards gave no data relative to the suction and force lifts of the water. These lifts may be such, as will account for the slowness with which the water is pumped out and the friction losses may not be the important difficulty.

Taking the view that the lift is *nil*, a 3-in. pipe will carry under the same pressure about 2.75 times as much water as a 2-in. pipe, the comparative carrying capacities being given roughly by the ratio $\left(\frac{3}{2}\right)^{\frac{5}{2}}$, so Mr. Fulton's claim for the new arrangement, with a 4-in. suction to reduce intake losses, is quite conservative, assuming that the pipe friction is the only resistance to be met.—EDITOR.]

Best Method of Timbering A Mine Parting

I would like to see in COAL AGE the expression of the opinions of readers as to the best method of timbering a lie or mine parting, under the following conditions: The mine roof is tender and the two tracks are so close together as to make it impossible to set a post between the main track and the side track.

This question is suggested for discussion by readers and I hope it will receive a generous response.

NOAH BURTON.
Anglin, Ky.

Summary of the Mine Fire Letters

By John T. Fuller*

A tabulated recapitulation of the recent mine-fire discussion. The opinions advanced were surprisingly contradictory, but Mr. Fuller believes that the evidence shows the return should be closed off first.

*Consulting engineer, Honesdale, Penn.

Reviewing the discussion recently carried on in the columns of COAL AGE, one is tempted to ask, what answer is to be given to the original question.

The question was, "Disregarding local conditions, that modify any specific rule, is it not possible to prescribe in general whether a fire at the face of a pair of entries should be sealed off first on the intake or first on the return side of the fire?" It was also left as an inference that gas (firedamp) might be present.

Trying to place myself in the same mental attitude as the original questioner and approach the subject with a free mind open to conviction either way, I carefully reread the whole discussion and made a table in which I have tabulated the result of the vote and a digest of the reasons. A careful analysis of this table reveals the following:

Total letters written	32
Number of contributors to the discussion	32
Number advocating first stopping in intake	16
Number advocating first stopping in return	10
Number advocating both simultaneously	6
Number advocating either stopping first	1
Number who do not state which	2
	*35

Analysing now carefully the reasons given, I find that the chief reasons given by the intake advocates are:

(1) Because it is the coolest, easiest and most direct point of attack.

(2) Because it is then possible to work in pure air.

(3) Because the air supply can be cut off immediately.

(4) Possibility of an explosion is not sufficiently evident to offset the danger, inconvenience and delay incidental to working in a bad atmosphere.

(5) Because in most cases it would be impossible to put the first stopping in the return.

The "return" advocates on the other hand offer the following:

(1) Because by placing the first stopping on the intake there is danger of a gas explosion.

(2) By placing the first stopping on the return such an explosion would be avoided, owing to the fact that the mixture of smoke and gases of combustion would be forced back over the fire, aiding in extinguishing same, and by their expansion due to the heat of the fire, force back the air from the intake, thus preventing the formation of an explosive mixture at the seat of the fire.

Considering, for the sake of argument, that the reasons pro and con above noted are the indirect evidence in the case, let us turn to the "direct evidence" of examples in the actual experience of the writers.

Intake Advocates—Have always closed off mine fires that way; nothing at all alarming has ever happened by so doing, and therefore this is most emphatically the correct thing to do.

Return Advocates—Have tried placing the first stopping in the intake with disastrous results in the way of gas explosions, while on the other hand have had no explosions when first stopping has been placed on return.

While my personal experience with mine fires has been confined to but three, none of which were of the nature of the fire in question, nevertheless, having in mind several explosions which to my knowledge had occurred in the anthracite coal region of Pennsylvania due to closing the intake first, I was one of those who recommended closing the return first, if possible.

Any fair-minded man will, I think, if he reads over and carefully analyzes this discussion along the lines I have indicated, come to the conclusion that, in spite of the majority of the intake advocates, the preponderance of evidence, backed by the proof of actual experience, is in favor of the "return advocates."

Therefore, considering myself as the original questioner, I would take my question to be answered as follows:

There is no general rule possible, but if gas is present or liable to be present, make every possible effort to place the first stopping on the return.

*The fact that some writers recommend two courses, such as "intake first or both simultaneously," acounts for the apparent discrepancy in this total with the number of letters received.

CONDENSED SUMMARY OF THE RECENT DISCUSSION ON MINE FIRES

Letter No.	Close Intake First	Close Return First	Both Simultaneously	Either	Not Stated	Reasons Given	Remarks
1	1		1			Closing the intake first is recommended, as otherwise the smoke is forced into the intake and fills it so completely that it is impossible to get so close to the fire on that side	Proper bratticing and short-circuiting of the air, with or without helmets, should remove this difficulty
2	1					Because the coolest and easiest place to work and in most cases it would be quite impossible to put in the return stopping first	Proper bratticing and short-circuiting of the air, with or without helmets, should remove this difficulty
3		1				No reasons given	
4	1					Because it would then be possible to work in fresh air	Proper bratticing and short-circuiting of the air, with or without helmets, should remove this difficulty
5		1				Because, by so doing, an explosion would be avoided, owing to the fact that the mixture of smoke and gasses of combustion would be forced back, over the fire and no chance given for an explosive mixture of gas and air to form near it	This conclusion is supported by cases in the actual experience of others
6			1			Because, when the air current is cut off from the fire, completely, there is no unnecessary delay and the danger from any accumulation and consequent explosion of firedamp is reduced to a minimum	Even in this case it is possible under certain conditions for sufficient air to be sealed in to cause an explosion at least strong enough to blow down the stoppings
7			1			No reason given	
8	1					Impossible to reach the fire in any other way	Proper bratticing and short-circuiting of the air, with or without helmets, should remove this difficulty
9	1					Because it cuts off the supply of oxygen promptly	So does placing the stopping in the return
10		1				Because it is safer and more effective in shutting off any fire to close the draft first and the air supply afterwards	
11				1		No reason given	
12		1	1			Because it prevents the smoke and fumes from traveling to other places in the mine	True, but the ventilating current is just as effectively stopped by placing the first stopping in the intake
13	1					No reason given	
14	1		1			No reason given	
15	1					No reason given	
16	1	1				If gas is not present the intake should be closed first in order to reduce the products of combustion in return, thus giving a better opportunity for building the second stopping. If gas is present or liable to be present would build first in return to minimize the danger of accumulations of gas with resulting explosions at seat of fire	Also recommends reversing the fan under certain conditions NOTE: As in this discussion it is assumed that gas is present or liable to be present this letter is assumed to be in favor of sealing the return
17		1				To avoid gas accumulation with consequent explosion and to force products of combustion back over fire to aid in extinguishing it	
18	1					In order to cut the air off immediately	Letter states that writer would try to prevent an explosive mixture forming, but fails to state how. Writer states that he has always sealed off fires this way
19		1				To confine products of combustion to fire area and so aid in extinguishing same. These confined gases of combustion expand by heat and push back fresh air that would enter at intake. If intake is closed first there is danger of explosive mixture forming	All these reasons have been supported and their truth sustained by actual experience
20	1					Working on fresh air. Is very emphatic that this is the best and only method	Writer strongly condemns reversing fan
21	1					Working on fresh air	
22	1					To work on fresh air. Does not consider the possible danger of an explosion to be sufficient to offset the danger and inconvenience of working in a bad atmosphere	Written by a man of long coal mining experience. Cites examples in his experience when such explosion occurred.
23 & 27	1					Very emphatic that this is the correct and only way. Strongest reason is the working in fresh air	Has always done it this way
24	1					To work on fresh air	
25		1				Because, in addition to stopping the flow of fresh air, past the fire it confines the products of combustion to the area of the fire which aids in extinguishing same and renders gas that may be present inexplosive. Avoids the ever-present danger of explosion when intake is closed first	
26					1		
28		1				To isolate the fire from the accumulated volume of gases in the return	This is rather ambiguous, as one of the reasons for placing the first stopping in the return is to confine the accumulated gases and products of combustion to the fire area
29	1					Reasons not definitely stated	Several good suggestions made
30	1					To work on pure air	States that fire is beyond control. Strictly speaking, is a mine fire beyond control until the mine must be either abandoned or flooded?
31					1		
32		1				Because of the danger of explosion of gas. A man of experience will hesitate long before placing first stopping in the intake	Written by a man of long coal mining experience. Cites examples in his experience when such explosion occurred

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Questions Asked at Fireboss Examination, Held at Cumberland, Wyo., Jan. 29-31, 1912

(*Continued from March* 16)

Ques.—What precautions are necessary in order to maintain a good current of air throughout the entire workings of a mine?

Ans.—To maintain a good air current in any mine it is necessary to build substantial, air-tight stoppings and to make all doors, brattices, air bridges, etc., airtight. The mine should be divided into separate ventilating districts and the air proportioned to the requirements in each district. It is necessary to so conduct the air as to cause the current to sweep the face, in each heading or working place. Wherever necessary to accomplish this, a temporary brattice should be constructed. Double doors should be used at all important points on main roads; so as to avoid the short-circuiting of the air at such points when cars or men are passing. All mine doors should be so hung as to close with the air and should be given a proper fall in order that the door may close with the current and not stand open. Trappers should attend all doors through which much coal is hauled on main roads. Finally, a reliable form of ventilator should be installed and kept running constantly, night and day.

Ques.—What is the least mixture of marsh gas and air (firedamp) that can be detected, and what is the greatest explosive mixture? What is the lower and what the higher explosive limit?

Ans.—The least percentage of marsh gas in air that can be detected will depend upon the means employed. Using the ordinary Davy lamp, burning common sperm oil, some observers can detect as low as 2 per cent. of gas, but ordinarily not less than 3 per cent. can be detected with this lamp. Lamps burning a volatile oil will often detect as low as 1 per cent. of gas, but owing to the heating of the lamp when burning a volatile oil, the indications are not uniformly correct. By the use of an indicator in a Davy lamp as low as one-half of one per cent. of gas is accurately shown.

The mixture of marsh gas and air reaches its maximum explosive point when the proportion of gas to air is 1 : 9.57; that is to say, the volume of air is about 9½ times the volume of gas. The lower explosive limit is reached when the proportion of gas to air is 1 : 13, or the volume of air is 13 times the volume of the gas. The higher explosive limit is reached when the proportion of gas to air is 1 : 5, or the volume of air is 5 times the volume of the gas.

Ques.—Why do you sometimes find a cap on the flame of a safety lamp when testing for gas, and again the gas will explode in the lamp without a cap having been observed?

Ans.—As explained in a previous answer, the presence of marsh gas in the mine air produces a plainly visible cap; but when olefiant gas is present associated with the marsh gas, the gas will often explode in the lamp before a flame cap has been observed.

Ques.—What are the dangers attending the use of the safety lamp?

Ans.—The chief dangers arise from the improper use of the safety lamp, due either to the ignorance or carelessness of the user. Such are exposure to a strong air current; exposure to gas for too long a period; making a quick or excited movement when the lamp flames; swinging the lamp or allowing it to fall; carrying too high a flame; neglecting to properly clean the lamp and put the parts together, or to properly inspect the gauze to detect any defect, or to properly test the lamp to ascertain its condition. A safety lamp is never safe when improperly handled, or in the hands of an incompetent person, or when the same is defective or improperly cleaned and put together.

Ques.—Explain just how you would carry your lamp when going to examine a known dangerous place containing gas.

Ans.—Hold the lamp erect and do not swing; screen the lamp from any strong air current, or concussion of air, or blast that may force the flame through the gauze. Approach the place cautiously and do not walk carelessly into the gas without making sufficient tests for the same. Raise the lamp carefully and slowly toward the roof, observing the flame for the first appearance of a cap when so doing. When a flame cap is first observed, lower the lamp promptly but slowly, and withdraw quietly from the place.

Ques.—Could a safe shot that did its work immediately succeeding a windy shot, produce a disastrous explosion; if so, why?

Ans.—The flame of the second shot, in this case, would be projected into an atmosphere of combustible gases produced by the first shot and the ignition of these gases would cause a local explosion, which would be intensified by the dust thrown into the air by the force of the blast. The extent of such an explosion would depend on the quantity of dust thrown into the air, its combustibility and the size of the openings. Under favorable conditions a very disastrous explosion would result.

Ques.—In a mine where mining machines are used to undercut the coal, which is blasted down with powder or other explosives, what precautions would you take and what is liable to occur even though no gas is known to exist?

Ans.—Owing to the large amount of fine cuttings and dust produced by the machines there is liable to occur a small local dust explosion at the working face if these cuttings are allowed to accumulate. A good circulation of air must be maintained at the working face and strict regulations must be made and enforced to prevent the occurrence of windy or blownout shots. A thorough system of inspection, charging and firing all shots should be adopted. Shotfirers should be appointed and authorized to refuse to fire any and all shots that may in their opinion be unsafe. Special attention must be given to see that every working place is thoroughly ventilated by an air current traveling at a moderate velocity.

Ques.—In an old mine generating explosive gases, what dangers arise that are not found in new mines generating such gases, and how would you overcome such dangers?

Ans.—An old mine contains many abandoned places, cavities in the roof due to falls, and other void places where gas can collect. Accumulation of gas in these void places renders the mine more dangerous, since the gas may be ignited by the lamp of a miner, or a roof fall may throw much gas out onto the entries. The same result will often occur from a fall of barometer, owing to the expansion of the gases that accumulate in the abandoned places. To overcome these dangers, in an old mine, the abandoned places should be thoroughly ventilated or closed tight and sealed. The air current in such mines should be made to sweep all void places and cavities where gas may collect. A more thorough inspection of the mine is necessary and a larger volume of air required to be kept in circulation.

For the Betterment of Living Conditions in Mining Communities

Problems of the Y. M. C. A. Mining Institute

By Charles L. Fay*

During the past year the Y. M. C. A. Mining Institute movement has more than doubled its membership in the anthracite coal fields of Pennsylvania. Seven district institutes now have a paid membership of over 5000 men.

A few branches in the bituminous region of Pennsylvania are doing good work. Institutes are conducted at Cabin Creek, W. Va., and the State Y. M. C. A., of Kentucky, is introducing special work for miners at Rim and Jenkins.

Teaching the Foreign Element

The institutes have thus far confined their work mainly to monthly meetings for the reading and discussion of papers on mining subjects. A few, however, have conducted successful mining schools and also schools in which to give the foreign miners a working knowledge of English, using studies in elementary mining for the instruction papers. In this connection it is interesting to note the development of instruction papers for use in the foreigners' schools.

M. S. Smith, a former secretary of the State Y. M. C. A. Bituminous Committee, Pennsylvania, first introduced the plan of teaching the foreigners by charts. Mr. Smith prepared the charts himself, using "store" paper and a marking crayon. Sentences were arranged that had to do with the miners' everyday work and experiences.

This crude plan was soon superseded by the "Roberts Method" (Peter Roberts, Ph.D., International Y. M. C. A. Committee, New York City), consisting of printed charts and lesson leaflets. Later, Col. R. A. Phillips, general manager of the Delaware, Lackawanna & Western R.R. coal department, conceived the idea of teaching foreign miners by the use of pictures, and recently the Delaware, Lackawanna & Western R.R. Co., on suggestion and by the initiative of Col. Phillips, at large expense and with great care, prepared a book entitled, "Mine Accidents and Their Prevention," which is so complete and comprehensive that it must be seen to be fully appreciated.

Plans of the Institute

Some of the methods and problems worthy of consideration may be indicated as follows:

A—Discussion of practical mining questions by members, at the monthly meetings, rather than the presentation of technical papers by experts. This is not to the complete exclusion of occasional technical papers or addresses.

B—More emphasis on the social and musical features of programs.

C—Every institute to operate a well conducted mining school.

D—Schools and occasional lectures (illustrated) at all mining towns.

E—The development of plans to meet the moral, educational and social needs of the thousands of boys in the mining communities. (One institute is now planning for experimental work in the way of special institute meetings for foreign boys.)

F—A study of the liquor evil and the promotion of campaigns of education and for legislation to minimize and overcome this greatest foe of the miner and the miner's home. (In one coal-producing county, estimates based on conservative data show that about $8,257,000 was spent during one year for liquor, or $24 to every man, woman and child in the county.)

G—The promotion of Thrift clubs for the study of domestic economy and the betterment of living conditions.

H—The Y. M. C. A. Mining Institute movement should be extended to every mining district in the United States.

The movement is no longer an experiment. It has proved its timeliness and its value to miners, operators and society. A meeting of representative mining men, from all parts of the country, to devise ways and means for a wide and aggressive campaign of development and extension, would result in great good. It seems to be the next logical step.

*Mining secretary, State Y. M. C. A. of Pennsylvania.

Electrical Burns

C. A. Lauffer, in the *Electrical Journal*, makes the following observations on flash burns from electric currents:

"Flash burns of the skin are usually burns of the second degree. That is to say, while destroying the outer layer of skin (the epithelium) they do not injure the inner layer (the corium) nor the deeper tissues. At first these burns may present a mere congestion; the skin is red, as from exposure to the sun, and they have the appearance of merely a first-degree burn, and scarcely appear to need dressing and bandaging. But there is pain and some redness. By the second day huge blebs or blisters may have formed. Usually the hair is scorched; often the outer skin is blown off, and the surface looks ragged. Under proper treatment of these cases there is seldom any formation of pus, and they will heal up, usually without leaving a scar. I have treated many such burns with the happiest results. I have ministered to men whose features were so altered by burns and whose eyes were so badly swollen, that their own mothers would not have known them. To the uninitiated it seemed they were scarred for life, yet within two weeks they were able to resume work, and within two months no trace of their burns was discernible.

Treatment of Flash Burns of the Skin

"In treating flash burns the first requisite is to obtain the highest degree of surgical cleanliness by use of ethereal soap applied with numerous cotton sponges (using sterilized absorbent cotton, such as is sold for medical uses) and the application of sterile gauze dressing, well covered with unguentine. I find this ointment uniformly reliable; it soothes the pain and promotes recovery. A loose gauze bandage is applied and the part permitted to rest.

"The subsequent treatment consists of daily redressings. When the blebs are large, we scissor them open freely, but allow the outer skin to remain for some days, as it is in itself a splendid protective covering.

"Such burns must be washed clean. With this precaution there is little liability to infection with its accompanying pain, the formation of pus, and a resulting long term of disability. But should they become infected with formation of pus, I would at once trim away the skin débris, so as to allow no pockets for the retention of infection. When the burn is not infected; that is, when the pus-producing bacteria do not invade the wound, the dead skin is removed within a few days, as soon, in fact, as the inner sensitive layer of the skin has had a chance to harden somewhat, and to lose its excessive sensitiveness. When the healing has progressed I sometimes apply 10 per cent. ichthyol in petrolatum, to facilitate the formation of normal skin. After recovery, in most cases, the skin remains red and sensitive for some weeks. I instruct the patient to wear canvas gloves and otherwise protect the new skin from grime and weather, as it is prone to eczema.

"The dry, open method of treating such burns, namely, that of freely dusting on the wounds powdered stereate of zinc and exposing the injury unbandaged to the air, is more or less successful in hospital practice, but not adapted to patients who are moving around, especially those who may live in the streets and in dirty houses, and who may return to work before complete recovery."

Apparatus for Artificial Respiration

There are three forms by which artificial respiration can be administered;—Sylvester's, Shaffer's and Marshall Hall's. The first two are those most in use. The Sylvester method is used by the most prominent instructors in this country, because they believe it the most efficacious. However, there are many people who hold firmly to the Shaffer method, mainly because in that system of procedure the tongue does not have to be controlled. The patient lies prone and his tongue naturally remains in the correct position.

The Sylvester Method

The Sylvester method primarily consists in rhythmically moving the arms to an extended position above the head and then pushing them back into a doubled position over the lower vest pockets, wiping them forcibly down the flanks so as to produce extended compression and a binding tension across the stomach. The pull on the arms enlarges the chest, the air enters and fills the lungs. When the arms are lowered and pressure applied the chest is thereby deflated and the air leaves. This treatment has received other developments. It has been recognized that deflation is not satisfactorily attained by a mere movement of the arms. In proper treatment, the elbows of the patient are thrust with some violence into his sides, and in order to make the deflation complete, it is generally recognized that it is well to have a second man ready to put pressure on the lower part of the chest at the same time as the lungs are being deflated by the side compression of the arms. But the use of two men is not without advantage, because the deflator as we may call him, seeing that he does nothing else but deflate, may be over-zealous and compress the lungs when the inflator is trying to inflate them.

A Mechanism Following Sylvester Methods

There is a great deal to be gained by synchronous work, and this is secured by the Fries apparatus, which is being sold under the name of the "Synchron" appliance. It has just been introduced into America, and we believe so far has not been recognized by those who have knowledge of artificial respiration, but from outward appearances it would seem to meet with all requirements. There is little that is more tiring than taking part in resuscitation work. There is but little encouragement for those who are engaged in performing it. Few indeed can be induced to remain at the work for perhaps five long weary hours, when all evidence seems to favor the notion that the patient is dead beyond all recovery. The Sylvester operator must kneel at the patient's head, must lower his own body forward three or four feet, must press the elbows firmly, and then draw back beyond the perpendicular. This is no easy task, especially when many times repeated, and the men who have been working at it without response for an hour or two soon convince themselves that the man is dead beyond recall. With this new machine the patient is fixed to the apparatus, and thus one man can do the work with less labor than two would otherwise expend. The band over the chest operates automatically. It goes completely over the stomach, so that a large deflation is assured, and this occurs at the instant desired, hence the word "Synchron" is well earned.

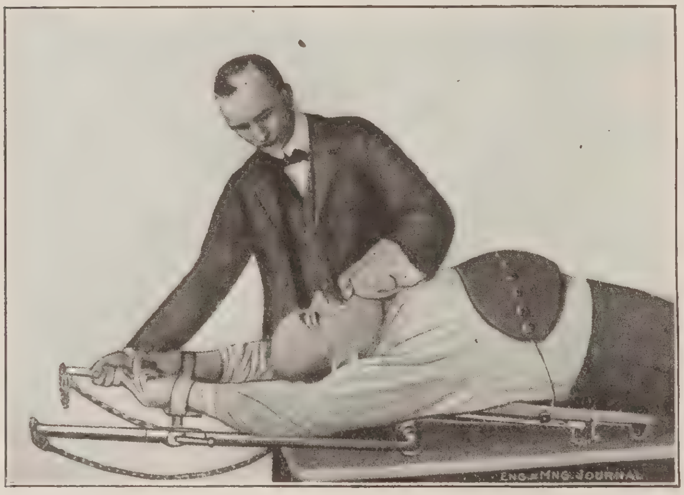
The Air Passages

The patentees recommend the extension of the tongue by hand and show that this can be done by the man who works the appliance, but it would be better to hold the tongue in place by bandaging, as is the general practice in the United States.

The shape of the apparatus is such that the patient's head is naturally thrown back in an abnormal position. like that of one whose neck is resting on a rolled up coat. This position is that recommended by physicians because it makes a direct passage for the air from the nose and mouth to the lungs.

Dr. Fries, a Swedish physician is the inventor. Prof. J. E. Johannson has made several severe practical tests of the contrivance in the Physiological Department of the Karolinska Institute at Stockholm. Also at the Serafimerlasarett, the Royal Hospital of Stockholm, it has been well tested and is now installed for general practice. The appliance has also been adopted by the Life Saving Society and approved by the directors of the Association of Swedish Physicians. At the royal hospital at Stockholm this apparatus proved successful in several cases of asphyxia after manual treatment had been abandoned as hopeless. A. E. Sylven of 29 Broadway, New York City, is the representative in the United States for the sale of this apparatus.

It must be remembered that while the first duty is not to get the apparatus but to attend to the patient, another can be sent for it. As artificial respiration must usually be conducted for a long time, there will be plenty of opportunity for the apparatus to arrive and do good work, at least in all cases where the resuscitation of the patient is difficult.



The Synchron Respiration Apparatus in Operation

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

Representative Lee of Pennsylvania has offered a bill to provide for compulsory arbitration in coal-mining controversies. The bill has been referred to the Committee on Interstate Commerce, discussed, and referred to a subcommittee. It provides that in case a controversy arises between a carrier and its employees or between the owner of a coal mine and the employees of such owner or owners, "seriously interrupting or threatening to interrupt the business of said carrier, owner or owners, the chairman of the Interstate Commerce Commission and the Commissioner of Labor shall, upon the request of either party to the controversy, with all practicable expedition, put themselves in communication with the parties to such controversy and shall use their best efforts, by mediation and conciliation, to amicably settle the same; and if such efforts shall be unsuccessful, shall at once endeavor to bring about an arbitration of said controversy in accordance with the provisions of this Act."

The bill goes on to provide for the submission of the controversy to the arbitration of a board of three persons in case it cannot be settled by the mediation and conciliation referred to above.

Representative Lee comes from the heart of the anthracite region in Pennsylvania. As a Democrat he has interested Speaker Clark, Representative Oscar W. Underwood, the majority leader, and Representative William B. Wilson, of Pennsylvania, chairman of the labor committee, in his plan, and he thinks he has their support. He hopes to have the bill made a party measure.

Mr. Lee says: "I am perfectly willing that my bill should be amended in any way that will enable it to get through Congress more quickly, so long as it is effective. The time to pass such a measure is now, and not after a strike has come upon us."

Decision in the Pittsburg-Lake Erie Rate Case

The Interstate Commerce Commission has just handed down its decision in the long drawn-out controversy between John W. Boileau and the Pittsburg & Lake Erie R.R. Co. *et al.*, with the result that the rate of 88c. per ton "for the transportation of bituminous coal in carloads from the Pittsburg, Penn., district to Ashtabula Harbor, Ohio, when for trans-shipment by vessel on the great lakes to points beyond" is found to be unreasonable and the rate of 78c. is prescribed for the future.

After a lengthy review of the situation, the commission offers the following interesting remarks on the conditions affected by the rate under complaint:

Viewed in the light of all the evidence and our own inquiries, the 88c. rate looks high. Complainants assert that there exists no power anywhere to let a shipper into a market by advancing the rate to another shipper. If the rate which the other shipper is paying is unduly low, we doubt whether this contention is tenable, and to this extent the general principle appealed to does not appear to us to be sound. But even though counsel have stated their contention somewhat too broadly, as applied to the situation in the Pittsburg district, it appears to point to the truth in this case. We think it only a fair inference from this record that the Pittsburg rate was raised step by step, not to bring it up to a level which the carriers might have regarded and defended as reasonable, but in order to let certain competing coal fields into the lake trade. And the record is conclusive that it is not a competitive rate.

Defendants argue that the lack of prosperity among the Pittsburg operators is due to excessive competition among the operators in the different districts. Granting that this be so, does that justify the imposition of an excessive rate upon the traffic from one of the competing fields? The Pittsburg field is entitled to a reasonable rate whether it brings the expected relief or not and irrespective of the specific channels into which the amount of the reduction in the rate will flow.

Rate Not Determined by Cost Alone

From the point of view of the specific cost of doing this particular business this rate is still too high; but, as we have said before, cost is only one of the elements entering into a rate. When we consider the coal rates from all the fields which will be affected by this change in the Pittsburg rate, the disturbance in established differentials, the possible deflection of the currents of coal trade and its effect upon operators elsewhere, the effect upon the carriers directly involved and the indirect effect upon other carriers, and all the other valid considerations, we are forced to the conclusion that a rate lower than this would not be just and reasonable under the conditions disclosed by this record.

In view of all the matters herein set forth it is our opinion, and we therefore find, that the present rate of 88c. is unjust and unreasonable, and that the defendants shall maintain for a period of two years from the date hereof a rate not to exceed 78c. from the mines in the Pittsburg district to Ashtabula Harbor, Ohio.

Alabama

Birmingham—The Maryland Coal Co., which is preparing to develop coal lands along the Frisco line in Winston County, is pushing preliminary work and expects to have an output from the Black Creek seam with 30 days. This new concern is headed by Henry F. De Bardeleben.

Sheffield—It was recently announced that a plan for reorganizing the Sheffield Coal & Iron Co. will shortly be submitted to the bond and stockholders. This concern is a New York corporation, organized in 1909 with a capital of $3,250,000, owning mines and collieries at this point and at Wise, Va.

Colorado

Boulder—Although the agreement effected recently between the American Fuel Co. and the members of district No. 15, United Mine Workers of America, has given employment to about 750 men who have been on strike for almost two years, the industrial war in the northern coal fields is still a long way from settlement. The Rocky Mountain Fuel Co., the National Fuel, the Frederick, the Brooks-Harrison and the Consolidated Coal and Coke companies have all joined in a notice to their nonunion employees in which they give assurance that they will not enter into any agreement with the union and will not under any circumstances discharge the nonunion miners without warning. The mines which have signed an agreement, represent 9.46 per cent. of the total production, and those which are still employing nonunion men, represent 91.54 per cent.

Illinois

Edwardsville—Twenty-five deeds of trust were filed here recently by residents of Leef Township, transferring coal rights on their property to Thomas Williamson, trustee. The deal involves about 2500 acres at $20 an acre, or a total of $50,000. The land is just east of Livingston and Williamson and the center of the tract is at the intersection of the Illinois Central and Big Four railroads. Mr. Williamson states that he represents Eastern capital, and that a mine will probably be opened on the property.

Hillsboro—The coal properties, recently purchased by the Chicago and Eastern Illinois R.R., include the two mines at Witt, and the Kortkamp mine at Hills-

boro; the Montgomery County mine, at Taylor Springs, and the Peabody mine at Nakomis. The Taylor Springs mine and the No. 2 mine at Witt, have an average capacity of 2500 tons a day, while the No. 24 mine at Witt and the Kortkamp mine have an average of 1750 tons daily, and the Peabody mine, at Nakomis, produces an average of 1000 tons a day. This gives a total production of about 10,000 tons a day for the five mines. The purchase, it is thought, will have a tendency to make work even better than heretofore, and will also tend to create a business boom in the towns where the mines are located. No change will be made in the operation of the mines at the present time.

Tilden—Two miners were perhaps fatally injured, and three others severely hurt, the latter part of last week, when the hoisting cage at the Tilden mine dropped 100 ft. to the bottom of the shaft. The accident was due to the engineer losing control of his engine.

Chicago—The Interstate Commerce Commission has recently made an examination into the alleged disciminatory rates formerly in force on coal handled from the Saline County field by the Big Four railroad. A differential, favoring the field to the extent of 3c. a ton, has been removed and the full rate demanded. In consequence, the O'Gara Coal Co. and five other operators in this field have brought complaint against the railroad. The O'Gara company does about 90 per cent. of the business in the territory, and its loss in consequence of the altered rate is said to amount to $240,000 a year. The other operators who are fighting the Big Four are the Big Creek Colliery Co., the Saline County Coal Co., the Wasson Coal Co., the Harrisburg Southern Coal Co., and the El Dorado Coal Company.

Indiana

Linton—The Vandalia mine No. 4 was flooded recently and had to be abandoned. The inflow of water came from old workings, nearby, and the men had not even enough warning to allow them to remove their tools. The loss is estimated at more than $10,000.

Indianapolis—A famine of anthracite coal is being experienced in many towns and cities throughout Indiana. This condition has prevailed for more than a week, although it is reported that thousands of cars are standing on sidings and in yards of the various railroads.

The pay of miners in the Indiana coal field for the half month ending Mar. 11, broke all previous records. Every mine in all the principal districts worked full time during the two weeks.

Terre Haute—The annual convention of District No. 11, United Mine Workers, which comprises all the Indiana field, except Clay County, was held here, Mar. 12 and 13, with 150 delegates in attendance. The scale committee made a report in favor of the demands made at the interstate joint conference at Indianapolis, but did not go into the details of the state contract, since the joint conference will reconvene at Cleveland, Mar. 20.

Kansas

Pittsburg—Another shotfirer was killed recently at Radley; this time in the Hamilton No 7 mine. One week previous, two shotfirers were killed in a mine near Radley, and a week before that another two shotfirers were killed in a Radley mine.

Kentucky

Frankfort—Articles of incorporation of the Long Fork R.R. have been filed with the railroad commission. The new road will be 20 miles long and will extend from a point in Floyd County, through a part of Pike County to the Knott County line. It will open up valuable coal and timber lands in Floyd and Pike Counties and develop mines that have not been operated heretofore on account of lack of transportation. The project is backed by West Virginia capitalists, who own land along the route of the railroad.

Louisville—Sweeping charges of rate discrimination, embracing an allegation that the Stearns Coal & Lumber Co. owns and operates the Kentucky & Tennessee Ry. Co. or *vice versa*, and that rebates are paid the coal and lumber company named, are made in a complaint against the Kentucky & Tennessee Ry., the Cincinnati, New Orleans & Texas Pacific Ry., and the Southern Ry. Co., filed before the Interstate Commerce Commission recently by the Tennessee Coal Co. The charges involve an alleged discrimination of 10c. per ton in rates from Freeman to Chattanooga and Atlanta as compared with the rates in force from Jellico to the same points.

Maryland

Cumberland—Preparations are being made to resume operations at the Potomac mine, at Barton, after an idleness covering nearly five years. This mine was once the backbone of the little-vein region about Barton, and when at its best employed about 200 men. The suspension at the mine was a great blow to Barton and Pekin as the miners had to seek work elsewhere.

Ohio

Cleveland—The amount of coal afloat at Ohio ports is not any larger than it has been in former years. The leading shippers say that there will be less than 500,000 tons in store in vessels at this end of the route on Apr. 1. Owing to the heavy local demand there is little lake coal coming forward and the chances are that some of the boats that have been lined up to load before the contracts with the miners expire will not be able to get cargoes. There is more coal afloat at Cleveland than at any other port. Vessels are holding about 150,000 tons of coal here, and most of it is consigned to the Canadian head of the lakes.

Coshocton—The entry which is being made into the side of the mine of the Columbus Coal & Mining Co., near Coshocton, is about completed and the mine will soon be placed in operation again. This entry was driven for the purpose of draining the mine which has been flooded for some time.

Columbus—Secretary Nigh, of the Michigan-Ohio-Indiana Coal Association, has brought suit on behalf of that organization against the Hocking Valley R.R. Co., to test the question of responsibility of railroad companies for short-weight cars. The railroad contends that it is not liable to any claims of this character involving shipments made while the old under-billing rule was effective. This practice consisted in billing the coal cargoes at 500 lb. less than actual weight in order to cover all shortages. The matter will be tested thoroughly in the courts.

Oklahoma

Poteau—The property of the Sutter Coal & Mining Co. was sold here recently by the sheriff. E. F. Swinney, of Kansas City, purchased both the mine and the railway owned by the mining company. The mine sold for $25,000 and the railroad for $35,000. The railroad is nine miles long and connects with the Kansas City Southern at Shady Point. The mine will be put into operation at once.

Pennsylvania

Bituminous

Washington—An action involving more than $100,000 worth of coal land in Chartiers Township was begun recently by James G. Morris, of Washington, who obtained a cautionary injunction against the Meadowlands Coal Co. to restrain it from further mining of coal under the Morris farm. The tract comprises 122,235 acres. Morris alleges that the coal company has been taking out coal at the rate of one acre a week and has failed to make the payments called for by the agreement, excepting an original $1000.

McDonald—After being on strike since Mar. 1, about 500 miners employed at the Jumbo mine of the Pittsburg Coal Co. have returned to work. The men went out because of orders received from

the company compelling the machine men to use safety lamps. The agreement is to last until Apr. 1, and, by that time, the district convention will be over and a more definite settlement between the men and the company will likely be made.

Clearfield—The jury in the car discrimination case of the Beulah Coal Co. against the Pennsylvania Railroad Co. recently brought in a verdict for the plaintiff for $338,728.20, which is threefold the amount of damage it was found that the company had suffered by reason of the alleged discrimination. This makes the fourth case of this kind decided against the Pennsylvania Railroad in Clearfield. The awards in the other three cases were as follows: Sonman Coal Co., $145,830; Puritan Coal Mining Co., $72,000, and Walnut Coal Co., $74,000. All the cases will be appealed.

Du Bois—A fire on Mar. 13, did about $15,000 worth of damage to the plant of the Cascade Coal & Coke Co. at Sykesville. The fire originated in a large coal storage bin in the tipple and was confined to this locality.

With all the mines in this section working full time in anticipation of a possible shutdown, Apr. 1, the railroads are kept quite busy and every available man is being used. The Avoine mine at Fuller has been reopened. The mines at Tyler are running full time. The Buffalo & Susquehanna, the Buffalo, Rochester & Pittsburg and the Erie are all getting out as nearly their maximum output as the labor supply will permit.

Connellsville—The coke market in the Connellsville region has taken another leap. A prominent producer said recently that 2000 more men are needed in this district in order to fill orders already booked.

Uniontown—The H. C. Frick Coke Co. has recently ordered into service 462 additional ovens. These ovens are being fired this week and will give the Frick company a total of approximately 18,000 ovens in blast or about 84 per cent. The Frick company has also given orders to have the Filbert coal-loading plant put in shape for operation, and it is expected to begin loading coal there at once. The Fretts plant of the South Fayette Coke Co. is being fired this week and the entire 80 ovens will be put in operation as fast as men can be secured. The Banning Coke Co. is firing the 76 ovens at the Wineland plant, which have been idle for almost a year.

Anthracite

Scranton—Anthracite coal sold at tidewater during February for an average of $4.89 a ton, and as a result the increase to the mine workers under the sliding scale is 7 per cent.

First-aid men in the Diamond colliery of the Delaware, Lackawanna & Western Co. successfully demonstrated their methods on three men overcome by afterdamp following an explosion of gas, in which one man was burned to death. For an hour and a half the first-aid crew worked on Sidney Baker, mine foreman, and two other men, inducing respiration by artificial methods.

Pittston—A coal breaker underground is to be the latest novelty in the mining industry in this city. Hogan & White, who recently acquired possession of the Bowkley tract, have commenced operations. The firm plans to erect a set of coal rolls and screens inside the mine, and to prepare the coal there, after which it will be taken from the mine in assorted sizes. The seam which is being tapped is 20 ft. high, which makes this arrangement an easy possibility.

Wilkes-Barre—The new washery of the Hillside Coal & Iron Co., which has been under construction for several months past, is now completed. The structure is considered one of the most uptodate in the valley. It will take coal from the Butler, Lawrence and Thomas shafts.

According to reports of the mine inspector for the seventh anthracite district, the Prospect colliery, of the Lehigh Valley Coal Co., at Wilkes-Barre, prepared 1,157,667 tons of coal during 1911. This is stated to be a world's record for the greatest amount of coal produced by one colliery in a year.

Tamaqua—Because 18 nonunion men failed to join the ranks and wear union buttons; 700 employees of the Nesquehoning colliery of the Lehigh Coal & Navigation Co., near Mauch Chunk, went on strike, Mar. 11, and declared that they would remain away from work until the nonunionists joined the ranks. Subsequently, the movement spread to the Coaldale colliery, throwing idle about 1600 men altogether.

Pottsville—February was the biggest month for coal production that the Philadelphia & Reading Coal & Iron Co. has had in its history. Coal trains were sent from here every half hour during the month. Reports for the past five months show that 4,069,000 tons of coal were shipped.

Utah

Salt Lake City—Fifty-four owners of coal lands in Emery County, Utah, have formed a company known as the Emery Coal & Coke Co. The incorporators have turned their lands over to the company and taken stock in return. It is believed that the organization of this concern is another step toward the consolidation of the coal interests of that section. J. R. Sharp, a brother of William G. Sharp, president of the United States, Smelting, Refining & Mining Co., is a dominant factor in the new organization. The lands of the company are located near the townsites of Emery and Ferron.

West Virginia

Fairmont—The Consolidated Coal Co., which operates 40 mines in this section, employing upward of 6000 men will, in the early spring, put into full operation all plants owned by the company. Some of the plants have not been running full time for the past year and as soon as men can be secured the mines will start full blast. Fifteen hundred men will be brought to this section to operate these plants within the next few weeks.

Bluefield—The owners of 6000 acres of coal land in Dickenson and Russell counties recently appeared before the senate committee on railroads of the Virginia legislature and argued in favor of a bill requiring railroads to connect with parallel lines. The bill was reported favorably. The proprietors of the coal field told the committee that they had bought the land several years ago, expecting to get railway connection with the Carolina, Clinchfield and Ohio. They had offered to build a line from their mines to the railroad tracks, but the railroad would not let them connect. Even after offering to give their line fee simple to the railroad, they said, a connection was refused them.

Fire broke out at the steel tipple of the Pocahontas Consolidated Collieries Co., in the morning of Mar. 10, causing a loss estimated at about $2000.

Sutton—The holdings of the Cosmopolitan Coal & Coke Co., in Braxton County, were recently sold here at sheriff's sale and bid in by W. H. Martin of Uniontown, Penn., for $49,800. The property, consisting of about 10,000 acres of coal land, was mortgaged for several hundred thousand dollars.

Wheeling—The annual convention of the miners of the fifth and sixth subdistricts of Ohio, which include six counties in eastern Ohio and three counties in northern West Virginia, opened here Mar. 14 with 200 delegates in attendance. The sentiment of the meeting was expressed as in favor of a strike Apr. 1, unless the miners' full demands, are granted.

Canada

Calgary, B. C.—A car shortage which is holding back the work at various coal mines and causing them to curtail their outputs, and a general stagnation which necessarily follows the strike of seven months' duration in the Crow's Nest Pass, last summer, have practically killed business in that section of Alberta and British Columbia.

Russia

St. Petersburg—Forty-five miners were killed as the result of an explosion in the Italianka coal mine, Mar. 16.

Personals

Josiah V. Thompson, coal operator, of Uniontown, Penn., is a candidate for delegate from the twenty-third congressional district to the Republican National Convention.

John H. Jones, president of the Pittsburg-Buffalo Co., was chosen to act as spokesman for the operators at the joint conference of operators and miners in Cleveland, Mar. 20.

Timothy W. Sprague, of Boston, has just returned from a trip to Colorado which he made for the purpose of looking into the production and development of several Colorado coal fields.

John A. Roan, formerly manager of mines for the Sunday Creek Coal Co. of Columbus, Ohio, has resigned as manager of the Log Mountain Coal Co. of Bell County, Ky., and returned to Columbus.

John R. Rittman has resigned his position as superintendent of the Lovington mine, near Decatur, Ill., and will be succeeded by Dan Cameron who has been connected with the company for a number of years.

J. C. Kolsom was elected president of the Indiana Bituminous Coal Operators Association at the regular annual meeting, held in Terre Haute, Mar. 13. Hugh Shirkle was chosen vice-president and Philip Penna, secretary.

J. R. Pill of Birmingham, Ala., well known in industrial circles, has been made general manager of the Corona Coal & Iron Co. properties, recently purchased by Edgar L. Adler, with mines at Corona, Coal Valley and Patten, Alabama.

E. J. Wallace, until recently with the Mississippi Valley Fuel Co., St. Louis, Mo., has been appointed Western sales manager of the Dealers Fuel Co., of Nashville, Tenn. Mr. Wallace will make his headquarters in the Wright Building, St. Louis.

Louis Smith of Chicago has been appointed resident manager of the Spring Valley, Ill., mines of the Spring Valley Coal Co., to succeed the late J. H. Luther. Mr. Smith was formerly connected with the Chicago office and is thoroughly conversant with mine matters and with the business of the company.

Obituary

James Jones, founder of the Pittsburgh-Buffalo Co., and one of the most widely known coal operators in the United States, died in the afternoon of Mar. 17, following a stroke of apoplexy. He is reputed to have left an estate valued between $5,000,000 and $6,000,000, which includes interests in subsidiary companies of the Pittsburgh-Buffalo Co., in Pennsylvania, Ohio, Virginia, West Virginia and Kentucky. Mr. Jones was born in Wales and arrived in this country in 1858. His first stopping place was Mount Savage, Md., but it was only a few years before he moved to Pittsburg. He served through the Civil War with conspicuous bravery. In 1878, Mr. Jones leased the Osceola mines from Judge Thomas Mellon, founder of the Mellon National Bank, and formed the Osceola Coal Co. He later formed a partnership with the late W. L. Scott, of Erie, Penn., for a time, and after successfully organizing and operating the Catsburg Coal Co. and the Rostraver Coal Co., Mr. Jones, in 1896, took his five sons into partnership and formed the company known as James Jones & Sons, at that time the largest shippers of coal in the Pittsburg district. At the formation of the Monongahela River Consolidated Coal & Coke Co., in 1899 an offer for the Jones interests was finally accepted and subsequently Mr. Jones and his sons formed the Pittsburgh-Buffalo Co., with Mr. Jones as chairman of the board of directors. After selling a number of his coal properties to the Monongahela River Coal & Coke Co., Mr. Jones purchased a large tract of land in Hazelwood and diverted a portion of his time from his mining interests to building homes for working people, and at his death was one of the largest small home owners in Pittsburg.

Construction News

Latrobe, Penn.—The H. C. Frick Coke Co. is preparing to sink an air shaft at its Marguerite plant. S. J. Harry has been given the contract.

Pottsville, Penn.—The Lehigh Valley Coal Co. has under consideration the installation of an electric plant and haulage system at the Packer collieries near Shenandoah.

Lawrence, Mass.—The contract for a 10,000-ton reinforced-concrete coal pocket at the new print-works department of the Pacific Mills has been awarded to the Aberthaw Construction Co., Boston.

St. Clairsville, Ohio—The Provident Coal Co., of Cleveland, Ohio, will, next month, begin work on opening and equipping a new mine, at Fairpoint, Belmont County, Ohio. About $300,000 will be spent in developing this property.

Colorado Springs, Colo.—H. McGarry, of this city, and John T. Milliken, of St. Louis, have bought the Pike View mine and 1760 acres of coal land north of here. They will spend $35,000 in improvements to increase the daily output of the plant to 1000 tons.

Baltimore, Md.—It is the intention of New York capitalists to build a large power plant, 40 miles west of Chambersburg, Penn., on the 2500-acre property of the Mt. Equity Coal & Coke Co., to furnish electric power for the entire Cumberland Valley from Carlisle, Penn., to Winchester, Va.

Du Bois, Penn.—The Miller Construction Co., of Lock Haven, Penn., has taken the contract for building the four-mile extension of the Buffalo, Rochester & Pittsburg R.R. to run through Jacksonville and tap the company's new coal field in Indiana County. The work is to be done during the coming summer.

Publications Received

REVIEW OF THE COAL TRADE IN 1911. Edited by Hubert Greenwell. 162 pages, 5½x8½ in. 1s. The Colliery Guardian Co., Ltd., London.

A comprehensive review of the British coal trade during the past year.

ANNUAL REPORT OF THE STATE MINE INSPECTORS OF WYOMING, 1911. By George Blacker and W. E. Jones. 36 pp., 6x9 in.

Separate reports are given from the two inspection districts into which the coal mines of Wyoming are divided. No attempt is made to combine the statistics compiled for each section, in order to present totals for the entire state. The reports are for the fiscal year ending Sept. 30.

MECHANICAL STRESSES IN TRANSMISSION LINES. By A. Guell. Bulletin No. 54 of the Engineering Experiment Station, University of Illinois. 36 pages, 6x9 in., illustrated. Free on request.

Of the stresses to which lines of wire for the transmission of electric current are subjected, this bulletin discusses the following three: (1) dead weight; (2) wind pressure; (3) change of temperature. Approximate and exact formulas are derived for use in the calculation of such stresses. A numerical example given shows that for long spans and great sags the parabola method of calculation, commonly used by engineers, is inadequate. Evidence is presented to show the superior advantage of the catenary method, and also to show that this method is sufficiently simple and accurate to serve the purposes of practice.

Trade Catalogs

Scranton Acetylene Lamp Co., Scranton, Penn. Leaflet. The Scranton Acetylene Mine Lamp. Nine pages, 3x6 in., illustrated.

J. R. Robinson, Pittsburg, Penn. Booklet. "The Turbine Fan and the Ventilation of Mines, Power Houses and Buildings." 20 pages, 5x9 in., illustrated. Five pages of useful information and data in connection with mine ventilation are presented in convenient form for mine foremen and engineers.

Myers-Whaley Co., Inc., Knoxville, Tenn. Catalog of Shoveling Machines for underground and surface work. 20 pages, 8x10 in., illustrated. These machines are built to load coal or rock in seams as little as 50 in. in height; electricity, gasoline, compressed air or steam may be employed for motive power.

Industrial Notes

Roberts & Schaeffer, Chicago, Ill., have recently placed an order with the Robb Engineering Co., Ltd., through their Calgary office, for a 16x16-in. Robb-Armstrong automatic engine, direct-connected to a 185-kv.a. alternating-current generator, and an 11x12-in. engine of the same type direct-connected to a 75-kv.a. alternating-current generator. These engines are to be installed at the plant of the Jasper Park Coal Co., Pocahontas, Alta., Canada, and are to be used for lighting and for motor purposes in connection with the operation of the mines.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

While the urgent demand prevailing in the Eastern market has eased off to a certain extent, the general tone throughout the country is unquestionably panicky. The entire situation hinges on the labor outlook, and should it become evident that there will be a deadlock between the miners and operators, coal prices will undoubtedly experience a spectacular rise.

In the East, at Atlantic Coast points, it is believed that such a rush for coal was never experienced before. While the stocks of the wholesalers continue to diminish, the tonnages being handled are so enormous that it seems certain the consumers must be accumulating a substantial surplus. Embargoes have been declared on some of the Eastern roads and buyers are paying premiums on coal already *en route* in order to insure prompt delivery. Retail prices on anthracite have advanced 50c. a ton at a number of points; the uncertainty in the labor situation and the small shipments being received are causing a widespread anxiety in this trade.

The Ohio mines are reported to be working only 25 to 35 per cent. capacity, because of the car shortage. The difficulty in obtaining sufficient of the Ohio product, in the markets supplied by it, is becoming serious. In West Virginia, bids from foreign markets are carrying prices entirely beyond the control of the local consumers; the first shipments to this trade have now been made and others will follow in rapid succession.

Heavy storing by the railroads in the Middle West continues to be the predominating feature in the trade there. The St. Louis market is particularly short, coal destined for there being diverted to Chicago, which is not receiving its customary shipments of the West Virginia product, because of the influx of foreign orders. Auctioneering methods of selling in St. Louis have been the cause of a sensational advance in prices, but it is believed that they have now reached the maximum.

Boston, Mass.

Stocks of Southern coals in this section are rapidly diminishing; every contract, for use locally as well as for bunkers, is being stretched to the limit and receipts are relatively small. Long detention at Hampton Roads and the near expiration of the contract year are also tending to create a large extra demand on coals that can be shipped all-rail from the mines. A number of large plants at inland points, usually dependent on tide coal, have been forced to make heavy purchases of the Pennsylvanias to tide them over. Panic prices have been paid for coal actually *en route,* in order that buyers might have some assurance of the cars coming through. There is a lively scramble for March delivery in fear of a general tie-up Apr. 1.

The Boston retailers advanced domestic sizes, Mar. 13, 50c. as follows: Broken, \$7.50; egg and stove, \$8; chestnut, \$8.25; pea, \$6.25; Franklin, \$9.25; Shamokin, \$8.25. It was also announced that no fill-up orders could be accepted.

The following is some guide to wholesale prices, although they are extremely hard to follow in a market of this kind:

Clearfield, f.o.b. Philadelphia	\$3.75@4.00
Clearfield, for shipment, f.o.b. mines	2.50@2.75
Clearfield, *en route*, f.o.b. mine basis	2.75@3.50
Pocahontas, New River, f.o.b. Hampton Roads	5.00
Pocahontas, New River, Boston, on cars	5.85@6.25
Pocahontas, New River, Providence, on cars	6.00@6.25

New York

The New York market appears to have steadied up to a certain extent in most branches during the past week. Not that prices have fallen off, but the demand is not so positively urgent and fears of a panic are no longer expressed. There is some hesitancy among consumers to stock further because of the ruling high prices, although stocks on hand among the wholesalers are generally conceded to be far below normal for this period. On the other hand, it is believed in most quarters that the large consumers have succeeded in accumulating some surplus fuel to tide them over a possible suspension at the mines.

Spot bituminous of ordinary grades may be quoted at \$4@4.50 with the better grades out of the market. Water freights continue high, about double that quoted under normal conditions, although plenty of charters are obtainable at these figures. There is a decidedly optimistic feeling among the bituminous dealers generally, regardless of whether the strike takes place or not.

In anthracite the supplies among the wholesalers continue low and none of the companies appear to be accumulating any surplus. The shortage is most noticeable in broken and egg.

We quote wholesale anthracite prices, f.o.b. New York, as follows:

Broken	\$5.50@6.00
Egg	5.50@6.00
Stove	6.50
Chestnut	6.50
Pea	5.00@5.25
Buckwheat No. 1	4.00@4.50

Philadelphia, Penn.

The uncertain condition of the labor situation still continues to spur the trade in this vicinity, and as a consequence, the dealers still complain that they cannot begin to get sufficient coal to fill their orders. Many dealers have absolutely refused to accept orders for pea, claiming that it is impossible for them to get it, or if they can, the wholesale price is such, that they do not feel like paying it, or asking their customers in turn to stand the difference. Under ordinary conditions, the retail price of pea in this vicinity is about \$4.75, but \$5.25 and \$5.50 are practically the ruling prices now, and very little of this size in stock at that.

Every size is moving off, and there is no guarantee given that any size will be delivered promptly. The dealers simply cannot get ahead. Some of them have been successful in laying in a little advance stock of the steam sizes, mostly buckwheat, against possible trouble at the mines, but the dealers as a whole have little or no stocks of coal, and if there is trouble Apr. 1, the anthracite business is likely to be brought to a standstill within a few weeks, at the most.

Pittsburg

Bituminous—Negotiations as to the wage scale have resulted in nothing important, which is precisely what has been expected all along, and the prospects for a suspension remain unchanged. The sharp scarcity in tidewater markets has abated in the past few days, and coal is about 50c. per ton lower in the districts which have advantageous rates there and which were getting fancy prices. Clearfield coal, for instance, stands at \$1.75@2 per gross ton at the present time, though a day may effect an entire change. Early last week Clearfield coal sold up to \$2.50. In the Pittsburg district prices are a trifle higher, if anything, but there is relatively little excitement. Slack has brought \$1.50 and ¾-in. \$1.75, slack being particularly scarce. The mines continue to run up to the limit of car supply, about 80 per cent. of full rated ca-

pacity. We quote: Mine-run and nut, \$1.50@1.60; ¾-in., \$1.65@1.75; 1¼-in., \$1.90@2; slack, \$1.40@1.50, per net ton at mine, Pittsburg district.

Connellsville Coke—The market advanced sharply for both foundry and furnace coke, but the pressure for spot furnace has decreased this week, the consumers who were buying actively last week having apparently gotten all they required for the time being. For several weeks the spot coke market has been very irregular. A fortnight ago there was a sale of a round lot of prompt furnace coke at \$2.50, although on immediately succeeding days there was coke available at \$2 or less. The middle of last week prompt furnace coke was bringing \$2.10 @2.25, but is easier today. Contract coke is not being negotiated to any extent, though two or three contracts expire Apr. 1. We quote: Prompt furnace, \$2@2.10; prompt foundry, \$2.75@3, per ton at ovens.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ended Mar. 2 at 396,010 tons, an increase of 5000 tons, and shipments at 4521 cars to Pittsburg, 6244 cars to points West and 1125 cars to points East, a total of 11,890 cars, an increase of 150.

Baltimore, Md.

An almost unprecedented demand for coal, and a still further advance in prices on all grades occurred in the Baltimore market during the past week; it is believed the trade never experienced such a rush for fuel before. The offices of the mining companies here have simply been glutted with orders, and, despite the strenuous efforts that have been made to take care of customers, a majority of the companies here are away behind in shipments, owing to the scarcity of cars.

Prices for all grades have advanced over those for the previous week. At the majority of the offices of Baltimore companies it was stated that low-grade coal which, in normal times, brings about 90c. per ton, was now selling at \$2.50 per ton, and in some instances it had been sold as high as \$2.75. The better grades have also advanced, those which ordinarily sold at \$2.50 per ton, now being disposed of at \$3.25, and higher. It is not now a question of price as any operator who has the product can name his own price for it.

Buffalo, N. Y.

The bituminous-coal trade is fast approaching a state of frenzy, with both producer and consumer very much alarmed over the outlook. There are many reports from certain districts that the supply is out or nearly so and almost any price is offered for spot deliveries, with here and there some factories already closed. Northern New York is suffering most, but there is now a fast increasing demand from Michigan.

Even Buffalo is now on the anxious list and dealers are showing confirmations of large orders of bituminous sold as high as \$3.60 delivered, with nothing said as to size or origin. The purchaser is in a panic if the delivery is not prompt, though the seller quite likely recalls the times when the same buyer has canceled orders because the price declined.

One dealer states that he sells all coal as accepted when it leaves the mine and declines to replace if the railroad confiscates it, which has not been done very much yet. Such precaution is made necessary because prices will drop sharply as soon as the English strike is settled, regardless of whether we have a strike or not.

Bituminous quotations are nominal at \$2.60 for Pittsburg three-quarter, \$2.50 for mine-run and \$2.25 for slack, but for spot delivery prices run all the way to \$1.75 higher. Coke is also up, the demand being for 50 to 75c. over the nominal quotation of \$4.25 for best Connellsville foundry.

Cleveland, Ohio

Conditions in the past week in regard to procuring sufficient coal to take care of requirements have become serious, and in consequence prices have advanced on coarse coal from 40 to 60c. per ton, and slack from 75 to 85c. per ton, with a great scarcity at that.

There is still a pronounced shortage of cars and operators are not running more than about 25 to 35 per cent. capacity. West Virginia shipments to this market are out of the question at this time, as that district is busy supplying coal for the European trade. It looks very much at the present time that there will be a coal famine in this district, strike or no strike, as there certainly will be a suspension for at least 30 days or possibly more, and there is little coal on hand.

Columbus, Ohio

As the time for the expiration of the present mining scale approaches, the large consumers are becoming worried and efforts are being made to store up for a suspension, which is now believed to be inevitable. As a result, all steam sizes are in good demand and premiums are readily obtained on these grades. The small sizes have also advanced sharply until nut, pea and slack are quoted at about \$1.10, and coarse slack at an even dollar.

It is estimated that during the past week the production has been only about 55 to 60 per cent. normal, and, in some cases, the percentage was even lower. Operators are making every effort possible to relieve the situation, but the car shortage cannot be overcome. It is impossible for the railroads to get the empties back to the mines, and, as a result, many of the mines were compelled to close down for a portion of the past week.

The strike situation in England is having its effect upon Ohio fields. The demand for bunker is taking much of the West Virginia fuel off the market, and, as a consequence, the Ohio product has a wider market. Much of the West Virginia Pocahontas and Fairmount gas coal is being shipped to the seaboard.

Retail trade has been rather active despite the higher temperatures. Dealers have been busy on small orders. Prices on domestic grades are still ruling firm in every particular.

Prices prevailing in the Ohio fields are as follows:

Hocking Valley	
Domestic lump	\$1.60
¾-in.	1.40
Mine-run	1.20
Nut	1.20
Nut, pea and slack	1.05
Coarse slack	0.95
Pittsburgh No. 8	
¾-in	\$1.35
Mine-run	1.15
Coarse slack	0.95
Pomeroy Bend	
Domestic lump	\$1.75
¾-in	1.50
Mine-run	1.25
Kanawha	
Domestic lump	\$1.40
¾-in	1.30
Mine-run	1.15

Hampton Roads, Va.

The British steamers "Statia" and "Chiverstone," loaded with coal for Rotterdam, Netherlands, and Port Said, Egypt, respectively, sailed from Hampton Roads recently. These two vessels are the first to carry coal from this port to foreign countries, which have been affected by the coal strike in England, and is the beginning of a large number due here during the next few weeks. The "Statia" has on board 4000 tons of coal for Rotterdam, and is the first coal shipment ever made from Norfolk to that port.

Another vessel, the British steamer "Denaby," is in port to load a cargo of coal for Las Palmas, Great Canary Island. Heretofore all the coal in that port has been received from the mines in Wales.

The supply of cars at the mines during the past week has been poor and what coal is loaded is moved to Hampton Roads very slowly. Very little trading in spot coal is going on and it is hard to quote a standard price on spot at the present time. One dealer who was pushed for spot coal earlier in the week paid \$4.25 a ton for 500 tons to accommodate the demand of his customer.

Charleston, W. Va.

That the coal operators are able to accept but about 30 per cent. of the orders offered, fairly illustrates the condition of the West Virginia trade. More orders are not accepted because the mines can only be worked about half time owing to the fact that cars are not available. The demand for coal and the failure to get sufficient cars to supply the demand has sent the price up, and those mines that are not compelled to use the entire output to fill contracts are once again making a good profit. In many instances the operators are now given an opportunity to recoup the losses of the past year or two, to which they are entitled.

With anything like an adequate car supply that would keep the mines of the state in operation, the output will exceed that of any other period in the coal-mining history of the state, while the revenue will likewise top all previous figures.

Louisville, Ky.

Coal prices in the Louisville market will probably begin to tumble in a short time. This may not occur for a few weeks yet, but Louisville consumers are fortunate in that they are always offered an opportunity to lay in coal at summer prices, which helps to tide them over the winter without serious trouble.

The retail dealers of Louisville have educated their customers up to the point where the winter supply is laid in during the summer months to an extent probably equalled in few other cities. It was this precaution which prevented widespread inconvenience, and more suffering, the past winter. River coal is now coming down in goodly quantities, and the harbors in this locality show evidence of the activity in that trade.

Memphis, Tenn.

The mine situation is steadily growing more distressing; in the west Kentucky fields foreign buyers are paying as high as $1.75 per ton for mine-run, which is about 90c. above the normal price. The high-grade coals have been extremely scarce and hard to get for the reason that there has been an unusual demand, as well as a car shortage. The western Kentucky operators are selling coal from day to day, and to the highest bidder.

While the following prices have been quoted for the last few days, it has been impossible to buy at these figures. Cahaba district has announced its minimum price for April, which is $2.25 per ton. However, there will be very little coal supplied to the domestic market at this price during the month of April should a strike go into effect.

The normal or natural markets are suffering for want of coal because there are foreign buyers on the ground and they pay prices that are far beyond the normal.

Prices quoted in west Kentucky are as follows:

No. 1 lump	$1.50
No. 2 lump	1.35
No. 1 nut	1.10
Mine-run	1.00
Screenings	0.75

Chicago

The net result of the expected strike of the miners, Apr. 1, has been an advance in prices to a basis of $1.75@2 per ton at the mines for practically all kinds of Western steam coal.

Smokeless coal has been the center of the greatest interest. Smokeless mine-run has sold at $5 at tidewater, which means $3.60 a gross ton at the mines. All available cars and boats are being brought into requisition to move this coal.

The only coal known of as having been sold spot on the Chicago market went early this week at $1.75 for mine-run. The coke market is strong in sympathy with the rest of the trade. In furnace and foundry coke the consumers want to contract for the third quarter of the year, but producers are backward about doing so.

Prevailing prices at Chicago are as follows:

Sullivan County:	
Domestic lump	$2.87
Egg	2.87
Steam lump	$2.62@2.87
Screenings	2.62@2.87
Springfield:	
Domestic lump	$2.82
Steam lump	$2.57@2.82
Mine-run	2.57@2.82
Screenings	2.57@2.82
Clinton:	
Domestic lump	$2.77
Steam lump	$2.52@2.77
Mine-run	2.52@2.77
Screenings	2.52@2.77
Pocahontas and New River:	
Mine-run	$3.80@4.05
Lump and egg	4.05

Coke—Prices asked for coke are: Connellsville and Wise County, $4.85; byproduct, egg and stove, $4.95; byproduct, nut, $4.75; gas house, $4.90@$5.

Indianapolis

Consumers in all grades are storing heavily here in anticipation of the strike. It is the general belief on all sides that a suspension will take place on Apr. 1 and that there will be a decided shortage of coal.

During the week past heavy tonnages of coal have been shipped into Indianapolis for storage purposes. This coal has been consigned principally to the railroads and large manufacturing interests who have kept the matter so quiet that the fact that storing was being done has not been generally known. The Pennsylvania R.R. appears to be the leader in this movement as they are accumulating an immense surplus of fuel which they are storing on the right-of-way within the city limits; the officials of the company do not deny the fact that they are anticipating trouble at the mines.

Among the dealers the talk varies considerably. Some seem to believe the situation will be acute while others are of the opinion that the outlook is not serious. It is the general impression, however, that the public will not suffer to any great extent, insofar as domestic consumption is concerned, at any rate.

Minneapolis—St. Paul

Should a cold wave strike the Twin Cities and remain any length of time, the fuel situation will be serious and a coal famine will surely be the result. The supply of all grades is limited, both on anthracite and bituminous. Anthracite sizes of nut and pea are not to be had and the dealers' stocks on stove are low. Steam users who have been adverse to laying in stocks in view of the strike troubles are beginning to realize that they have been regarding the situation too lightly.

Dealers, while interested in the progress of the wage-scale conferences, are no more conversant with the real strike situation than the public at large. Practically all the anthracite coal at Duluth, Superior and Ashland is exhausted, and nearly all the bituminous is contracted. Dealers say they have been reasonably busy, although not rushed. A lot of speculation is being made as to whether or not the strike situation will prevent the usual Apr. 1 reduction of 50c. on anthracite. Information in regard to this is generally received from the East about the middle of March, but dock men say they have heard nothing, owing to the labor situation.

St. Louis, Mo.

The last week or ten days has seen the most excitable market condition in coal-trade circles that St. Louis has known in years. The St. Louis market was governed largely by the panicky conditions at Chicago where the auctioneering methods of buying, simply put the market out of sight.

Conditions here are uncertain, but indications are that the market will not get any stronger, but probably break, unless discouraging reports come from the efforts that are being made to settle the different wage scales.

Coal that would usually come to St. Louis to take care of the local consumption is being diverted to Chicago, on account of the supply from West Virginia being diverted from Chicago to the Atlantic Seaboard for export. As long as this continues the local market will be strong.

Prevailing prices in the St. Louis market are as follows:

Franklin County	
Lump and egg	$2.25@2.40
No. 1 nut	2.25@2.35
No. 2 nut	2.00@2.10
No. 3 nut	1.85@1.95
2-in. screenings	1.75@1.85
Carterville	
Lump and egg	$2.15@2.30
No. 1 nut	2.00@2.10
No. 2 nut	2.00@2.10
No. 3 nut	1.85@1.95
Screenings	1.75@1.85
Mine-run	1.85@2.00
Standard	
6-in. lump	$1.90@2.00
2-in. lump	1.85@2.00
No. 1 nut	1.90@2.00
No. 2 nut	1.90@2.00
Screenings	1.35@1.45
Mt. Olive	
3-in. lump	$2.00
No. 1 nut	2.00
No. 2 nut	2.00

Coke is in good demand and hard to get at from $4.75@5, St. Louis. There is a good tonnage of smokeless coming forward that has been bought for some time, and anthracite is moving fairly well in the larger sizes.

There has been a heavy tonnage of Kentucky coal shipped in, with screenings anywhere from 50c. to $1, mine-run $1@1.40, nut $1.35@1.60, 1¼-in. lump $1.50@1.60, and 2½-in. lump $1.75@1.85, all taking a $1 rate to East St. Louis. Part of this is from the union Kentucky field, and these mines will suspend on Apr. 1.

Portland, Ore.

Coal dealers here regard the winter season as over and from now on till next fall the demand will be only the normal average. Stocks carried over are somewhat larger than usual, owing to the mild winter, despite the fact that a couple of Australian cargoes were canceled. It is thought the coal strike in England and Germany will have no effect on prices here as the Australian product is one of the price-governing factors on this coast.

Local prices have shown no decline as yet, and they are not expected to until the beginning of the storage period, a date fixed by the dealers themselves, and depending upon conditions in general. At that time values will be shaded $1 per ton as is always customary.

Production and Transportation Statistics

Car Situation

There is a further decrease of 5902 in the car surplus, the total surplus for the period ending Feb. 28 being 44,984 cars, as against 50,886 on Feb. 14, 1912. The decrease in surplus is reported in all classes of cars, the largest being 2402 box cars, while flat, coal and miscellaneous cars showed decreases of 580, 1225 and 1695 cars, respectively. The total car shortage (37,142) remained practically the same as in the previous period when it was 36,928 cars.

Exports

It is estimated that since the strike began in Great Britain, that country has lost the sale of 190,000 tons of bunker coal to the world's coaling stations. Orders for this amount have been placed in America, and deliveries will be made before the end of the present month. The following is the destination of this coal, in tons:

Gibraltar	17,000
Buenos Ayres	32,800
Naples	10,500
La Plata	24,000
Genoa	11,000
Las Palmas	37,000
Marseilles	14,900
Rio Janeiro	22,950
Port Said	12,300
Algeria	6,000
St. Vincent	5,200

Norfolk & Western Ry.

The following is a statement of commercial and company coal from mines on the Norfolk & Western Ry. for the month of February, in short tons:

Field	Commercial	Company
Pocahontas	1,067,876	99,353
Tug River	140,956	49,030
Thacker	175,786	57,894
Kenova	68,570	9,956
Clinch Valley	107,238	7,642
Total	1,560,426	223,875

The following is a statement of the coal and coke tonnage from mines on the N. & W. Ry., in the state of West Virginia, for the month of February, 1912:

From	Tipple Coal	Total Coal
Pocahontas	20,418	1,122,908
Tug River	3,247	189,986
Thacker	4,744	233,680
Kenova	8,714	78,526
Total	37,123	1,625,100

Note—Total shipments of coke, originating entirely in the Pocahontas field, amounted to 111,524 tons.

Foreign Markets

Africa

The South African coal production for the year 1911 was as follows, in short tons:

Transvaal	4,343,680
Cape	89,023
Orange River Colony	482,690
Natal	2,682,029
Total	7,597,422

Australia

Coal production for the first nine months of 1911 shows an increase of 249,934 tons over that for the same period in 1910. It is probable that the production for 1911 will show a heavy increase over that for 1910.

Great Britain

The following is a summary of the coal production in Great Britain for the year 1911, in tons:

England	193,231,139
Wales	39,845,058
Scotland	41,718,163
Ireland	84,564
Total	271,878,924
Total for 1910	264,417,588

Market Conditions—The miners have suspended work and there is no coal market. Negotiations for a settlement are still proceeding. Quotations on the last day of business were nominally as follows:

Best Welsh steam coal	$5.28@5.52
Seconds	5.04@5.28
Thirds	4.56@4.80
Best dry coals	4.62@4.80
Best Monmouthshire	4.44
Seconds	4.14@4.32
Best Cardiff small coals	3.96
Seconds	3.48

The prices for Cardiff coals are all f.o.b. Cardiff, Penarth, or Barry, while those of Monmouthshire descriptions are f.o.b. Newport, both exclusive of wharfage, and for cash in 30 days, less 2½%.

British Exports—The following is a comparative statement of the British fuel exports for the first two months of 1911-12, in tons:

	1911	1912
Anthracite	430,564	447,199
Steam	7,126,219	7,941,579
Gas	1,548,601	1,730,471
Household	247,708	264,903
Other sorts	489,552	552,007
Coke	169,873	222,040
Patented fuel	284,884	310,183
Bunker coal	3,056,722	3,066,978
Total	13,354,123	14,535,360

Financial Notes

At a regular meeting of the board of directors of the Coal & Iron National Bank (New York), a quarterly dividend of 1½% was declared, payable Apr. 1, to stockholders of record, Mar. 13, 1912.

The annual report of the Pittsburgh Coal Co. for the year ended Dec. 31 shows net earnings of $4,044,504, compared with $4,699,863 in 1911. The deduction of $1,563,775 for reserve, depletion, and depreciation against $1,678,374 in the previous year and of $1,088,790 in bond interest, compared with $1,056,039 in 1910, left a surplus of $1,391,937. The payment of $1,535,590 in dividends on the preferred stock left the surplus for the year at $38,347, against $611,860 in 1910.

The average price of white-ash coal, of sizes above pea, sold at or near New York between Perth Amboy and Edgewater, for February was $4.88 per ton. This compares with an average price of $4.81 in February, 1911. Price this year entitled all miners and mine workers, included in the anthracite strike commission, to an increase of 7% over the rates of wages fixed in said awards. Average monthly increase over such rates for the past nine years has been 4½%, and aggregate bonus paid under the sliding scale has amounted to approximately $35,000,000.

The Sheffield Coal & Iron Co. has no overdue indebtedness to general creditors, owes no money to its banks, and should subsidiary companies continue to earn their way, the properties could be held for a considerable time were it not for the default which occurred on Jan. 1, 1912, in the payment of $63,580 interest on the outstanding first-mortgage bonds, and the further fact that on Apr. 1, 1912, a series of notes, aggregating about $82,000, given by the company at the time of its reorganization, will mature. The above amount of $63,580 includes the coupons on a large number of bonds, the holders of which agreed to defer payment of the same from January, 1910.

SITUATIONS WANTED

Experienced store manager desires to make a change; has made good record; will furnish best references. Address Box 14, Coal Age. Mar. 23.

Advertisements under this head 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Mine electrician and armature winder desires to make a change; 16 years' experience; married; 35 years old; don't drink. Address Box 20, Coal Age. Mar. 23.

Position as master mechanic by a young man of electrical and mechanical experience; able to handle anything of either line around a modern equipped mine; Sullivan cutting equipment preferred; open for engagement after April 1. Address Box 17, Coal Age. Mar. 30.

Commissary man wants position; if you have an opening for a store manager, write to the National Commissary Managers Association, 801 Manhattan Building, Chicago; good men will be recommended without charge; inquiries treated confidentially if desired. Mar. 23.

Wanted—Change of position by experienced superintendent; have engineering experience; have worked colored and foreign labor, rope and electric haulages, air and electric machines; good record for tonnage and economy; 10 years' experience in charge of mines for some of the largest coal companies in United States. Address Box 18, Coal Age. Apr. 13.

MINERAL SPRING COLLIERY, Lehigh Valley Coal Co., as seen from the Wilkes-Barre Mountain, and an interior view of the breaker, showing shaking screens and chutes. The building is of steel construction throughout, sheathed with corrugated iron, and has a liberal number of large windows which contribute much to efficiency of operation.

COAL AGE

Vol. 1 NEW YORK, MARCH 30, 1912 No. 25

MOST of us have one viewpoint for mechanical installations and an entirely different one for human equipment. And nowhere is this fault more emphasized than in the individual himself.

A man receives $1500 a year. Viewed in the light of reason, that means but one thing: He has been able to capitalize his ability for $30,000, since $1500 is the annual income at 5 per cent. on that sum.

Now, $30,000 will buy quite a few mine motors, and any one of these machines will pull a much greater load than a two-legged human, but unlike the latter, the locomotives can't think, and are absolutely useless when not directed by intelligent thought.

It's right here the individual has it on the machine. The latter is a known quantity and the company will never get from it any more than a fixed maximum horsepower. The energy of a human varies within a wide range, and the capital value a company places on a man depends largely on the amount of sensible efficient effort he develops.

If we expect the corporation we work for to increase the capitalized value placed on us, it is essential that we treat with care the body on which our mind depends for strength and sanity.

A man can become of greater value to a company as time passes; a mine motor will never be worth a dollar more than it was on the day of its purchase. The whole matter is a purely business proposition. Capitalized ability is more to be desired than capitalized property. The income from honest effort generally creates happiness. The annuities from massed wealth not only breed idleness and discontent, but in the hands of incompetents and degenerates, are most potent of all causes of class hatred.

In one way, however, the motor and the man correspond; each must possess the faculty for staying on the rails. An employee who frequently jumps the track, landing oftentimes in saloons and dives, won't be capitalized at any huge sum.

The fellow who proposes to increase his valuation to $100,000 or $200,000, must think fast and travel straight. He must study, read, observe and labor not a minimum eight, but a maximum 12 or 15 hours a day.

The age for whittling sticks and swapping stories at the corner grocery passed with the kerosene lamp and the stage coach. Sound sense and sold virtue have been essential in all ages; it's the application of ideas that has changed. We might have all the reputed courage of the ancient Romans, but our army would be useless if equipped with bows and arrows.

Also, the man who slows up and complains that nobody is watching his earnest effort, is in a class with the fellow who believes luck carves all careers. Someone higher up is sure to set a real value on our work, and 5 per cent. interest on a true capitalization, based on quantity and quality of results produced, will eventually be paid us.

And speaking of luck, let us realize that such an element doesn't enter into a man's life when measured over a period of years. For a day, a month or a year, maybe Yes, but for a score of years, No.

More good men have been hopelessly ruined by once making a little easy money than were ever incapacitated by inherited inability. Things go not by luck, but law. Winds and waves are on the side of the best navigator.

der, double-drum, first-motion hoisting engine. The drums are 8 ft. in diameter, and each has a capacity of 5000 ft. of 1¼-in. wire rope; the flanges are detachable and will be replaced with higher ones later, as the slope lengthens. The engine is fitted with steam-operated brakes, friction and reverse, and Corliss valves, although the dashpots have been left off, to be added later when length of haul becomes a serious item. Extension piston rods, through the back cylinder head, equipped with crossheads, are provided to take up the weight of the piston. There is 140 lb. steam pressure at the throttle. This engine handles 15-car trips, each car weighing loaded 5000 lb., at a speed of 1500 ft. per minute.

Other units are a 250-kw., 3-phase, 60-cycle, 2300-volt generator, direct connected to an 18x24-in. Corliss engine, having a speed of 120 r.p.m., and a 25-kw., 125-volt, direct-current generator, direct connected to a high-speed 8x7-in. engine, running at 350 r.p.m.; this latter is used as an exciter set and is of sufficient capacity to take care of additional units. There is also a 40-hp. motor-generator set which is used as an exciter set while running, and the engine exciter is used only for starting and as an emergency unit.

The decision to adopt alternating current was due to proposed additional openings to be made later, a mile or more from the present one, and the intention to provide power for both mines from this one plant. The flexibility of the alternating current was also taken into consideration. Then, again, although the first cost of alternating current machinery is slightly in excess of direct-current apparatus, the low maintenance and operating cost of induction motors, as compared with direct-current motors, is so great that in 12 months it would more than pay the difference in first cost.

Boiler House and Steam Lines

The boiler house, 41x51 ft. 3 in., is located 79 ft. below, and 197 ft. horizontally from the power house. In locating this building, advantage was taken of the profile of the ground for fuel- and ash-handling. Coal is drawn from the slack bin into a one-ton side-dump car which is pushed on a track running into the boiler house on top of the furnaces, on a 0.5 per cent. grade in favor of the load. The ashes are drawn from hoppers under the furnaces into a similar car, operating in a concrete tunnel running the length of the building; this car, when loaded, is pushed out on the track supported on a pole trestle along the hill side, and the contents dumped down the bank.

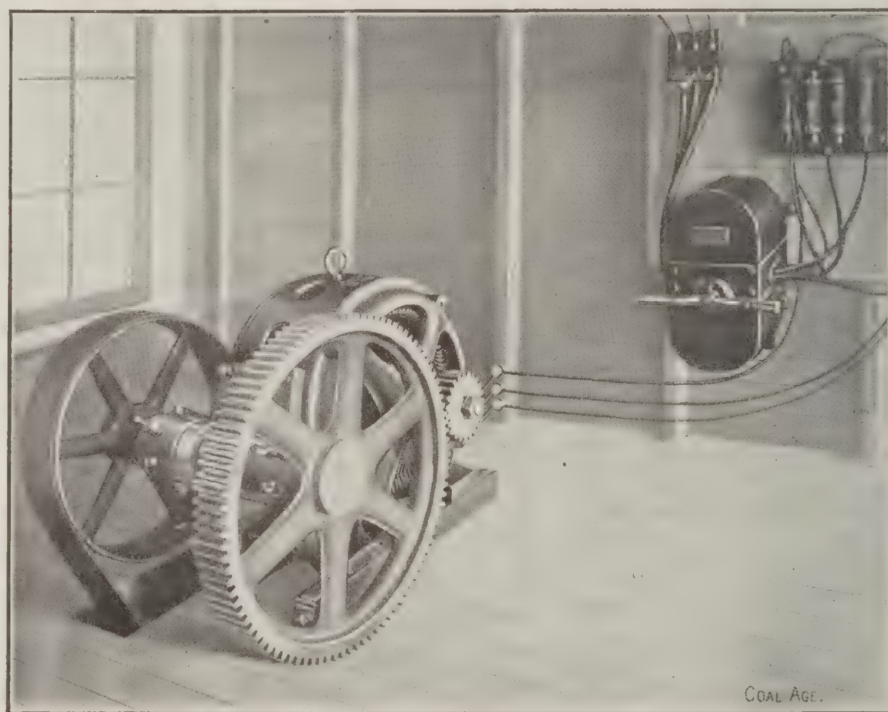
The building is similar in construction to the power house and contains three 300-hp., vertical water-tube boilers, having 150 lb. working pressure, set singly, in steel casings, and equipped with automatic stokers, feed-water regulators and automatic valves. Although at first glance this may appear an unnecessary refinement in equipment for a coal mine, it is justified by the saving in labor, one man handling this entire 900-hp. plant, including the firing and ash removal.

The 12-in. steam main from the boilers to the power house, 168 ft. long, is carried on a suspension bridge over the three side tracks. The span is 99 ft.; difference in elevation of the foundations of the towers is 49.75 ft., and of the tops 27.88 ft. The bridge consists of two ⅞-in., galvanized, steel-wire cables, spaced 48-in. centers, and ⅝-in. suspension rods, with longitudinal spacing of 5 ft. The minimum clearance from the top of rail is 22 ft. The bottom tower is 35 ft. from the track and behind a 6-ft. bank, while the upper tower is on the top side of a cut, 41 ft. above the rail, so it is plain that the danger of damaging either tower by a derailed car is eliminated. The grade of the bridge floor is 15 degrees.

All steam piping is of standard-weight pipe, lapped at the ends, and having rolled-steel flanges, forming a "Van Stone" joint. The connection from the 12-in. main to the boiler header is made with a 12-in. Harter flexible joint, which takes care of all expansions, the main connecting at the upper end to a long-radius, cast-steel L, securely anchored in the basement of the power house, from which distribution is made to the machinery. All valves are Fairbanks, extra heavy.

General Utility Shops

One large building houses the blacksmith, machine and carpenter shops. It is 35x82 ft. and 16 ft. high, of brick and steel construction, tile roof and contains a circular saw, boring machine, lathe and planer in the carpenter shop, and a power hammer, down-draft forge, blower, exhaust fan, pipe-cutting and threading machine, drill press, emery grinder, etc., in the machine shop. All machinery is driven from line shafting, to which is belted, in the carpenter shop, a 10-hp., 220-volt, three-phase induction motor, and, for the other machinery, a 15-hp., 220-volt, three-phase induction motor. A branch from the empty coal track outside leads into and runs the length of the building, ending over a concrete-lined pit in the machine shop for repair of the electric mine locomotives, of which there are at present two in operation, both being 4-ton Westinghouse Baldwin, having wrought-steel frames and fitted with arc headlights.



Conveyer Motor, Showing Potential Starter and Fuses on the Right

The locomotive trolley poles are located to one side of the center, which is necessary in low-roof mines to prevent accidents to employees. In addition to placing the wire to one side of the entry close to the rib, additional safety is provided by a wooden guard on each side of the wire which extends from the roof to 3 or 4 in. below the wire. While only 250 volts is carried on the trolley wire, which would not do material damage to persons coming in contact with it, the extra precaution of the wood guard has reduced danger of accidents of this kind to a minimum. This building, as well as the boiler and power house, is lighted with three 5-light cluster, 40-watt, tungsten lamps.

The Water Supply

Unfortunately, the nearest source of an abundant and pure water supply is over a mile from the town. This, of course, means pumping all the water used both

for domestic and boiler purposes. For the former, a storage supply is provided by a concrete tank of 50,000 gal. capacity, set on a concrete tower, 60 ft. above the ground. For the latter a 500,000-gal. concrete-lined reservoir was built on the crest of a hill beside the power house; from this reservoir, water flows to the feed pumps and later, when condensing apparatus is installed, will supply the condensers also. At present it is necessary to feed cold water to the boilers, but this is only temporary.

The proposition of handling the water from the stream is taken care of by two three-stage centrifugal pumps, direct-connected to three-phase, 2300-volt, 60-cycle induction motors, operating at a speed of 1700 r.p.m. One of these has a capacity of 150 gal. per min., and the other 250 gal. per min.; both operate under a 300-ft. head. The motors are 35 hp. and 60 hp., respectively, and only one pump is operated at a time, the other being held in reserve.

This plant is located in a brick building, 12x16 ft., and about 10 ft. from the bank of the stream. The motors are started and stopped by starters, located over a mile and a half away, in the power house. This use of starting apparatus, with a remote control, is one of the advantages of alternating current, as no extra or increased sizes of wire are necessary. The 4-in. suction from the pump leads into a sump on the outside of the building, which is connected to the stream by a 6-in. pipe provided with necessary strainers, check valves, etc. The building is waterproofed 6 ft. above the ground to prevent damage to machinery through high water.

It might be well to mention here that this source of supply was finally decided upon only after an exhaustive series of analyses of the water at the two extreme seasons of the year. A 6-in. cast-iron pipe carries the water from the pump to the 50,000-gal. tank, and thence to the reservoir in a 4-in. pipe, suitable valves being placed to turn all the flow into the latter without interfering with the domestic supply.

Electric Transmission System

The pole-line construction conforms to the best standards for this work. All poles are either 35 or 45 ft. long, spaced 100 ft. apart, and of good, straight, sound chestnut. Main-street poles, running through the town, carrying circuits of 2300 volts, are 45 ft. in length and placed 5 to 6 ft. in the ground; all corners are substantially guyed. On every fifth pole is placed an arm which extends out to the center of the road, about 20 ft. above the ground, on the end of which is hung a 60-watt tungsten series light, there being 26 of these distributed along the highways, on an independent 2300-volt circuit.

On each pole danger notices are printed in large black letters on a white background, which can be read from a distance. Some of the poles are equipped with steps from the top to within 8 ft. of the ground, and the management found that to protect the public as well as the company, it would have to prevent young boys from ascending these poles and stealing insulators; therefore, in addition to the "Danger" sign, there were placed on these stepped poles a $25 reward notice. Since this, there has been no trouble from that source whatever.

The Ventilating and Direct-current Plants

The ventilating equipment is in a large general building, divided into three compartments. One end contains the fan, 72 in. in diameter, delivering 100,000 cu.ft. of air per min. at a 1½-in. water gage and 300 r.p.m. The fan is belt driven by a 75-hp., 2300-volt, three-phase induction motor and starter. A reinforced-concrete tunnel carries the air from the fan to the two air courses. Concrete is extensively used in the mines for overcasts, etc. The middle compartment is a hospital for rendering first aid.

The third compartment, separated from the rest of the building by a 13-in. brick wall, contains a motor-generator set. Provision is made for three sets, but, at present, a 75-kw., 250-volt, direct-current generator, driven by a three-phase, 2300-volt, 60-cycle, 112-hp. induction motor, and a starter, is all that is necessary. The motor-generator set is mounted on an iron sub-base, and the speed is 650 r.p.m. A skeleton wood switchboard, for the outgoing mine circuits, completes the equipment of this room.

The machinery at present installed in the mine using the direct current supplied by this generator, is: Two locomotives, two small triplex sinking pumps, driven by back-geared, 15-hp. electric motors, two electric air rock drills, one 250-gal. triplex station pump, back geared to a 40-hp. motor, and six 20-hp. electric single-drum hoists. All the power leads run down the lower air course and at intervals branches are tapped off and run where necessary. Little water has been encountered so far in the mines, but a station pump will be installed later. All the motors for the plant were supplied by the Allis-Chalmers Co., Milwaukee.

The mine is being equipped with a complete telephone system, also electric indicators for showing the engineer the location of the trip he is handling. Shotfiring will be done entirely by electricity from the outside of the mine, while a system for checking the men going in and out will be established to prevent accidents happening from firing shots while anyone is in the mine. Electric air drills are being used for drilling the sandrock top in the headings and air courses.

Sociological Conditions

For the use of the miners, a bath house of brick will be built, equipped with 20 showers having both hot and cold water, and a locker for each man. The building will be divided into two compartments, one for the colored and the other for the white miners. A system of steam heating will be installed and an attendant, in charge at all hours, will be responsible for the proper care of the building.

The fire protection at Marvel has been given careful consideration. Fire hydrants are established at regular intervals throughout the camp, and hose carts are placed at convenient points, with plenty of underwriters hose to reach any desired locality. The water pressure from the concrete tank alone is sufficient to throw a stream from a 2-in. nozzle the necessary distance, while the pressure obtained when the pump is in operation and feeding directly into the mains is, in some places, more than 150 lb. per sq.in. Fire companies have been organized to fight any conflagration which might occur.

All the miners' houses are wired and the light is supplied at a flat rate, which is charged in with the rent. All lamp renewals are purchased at the commissary by the consumer. For use in the mines, 220-volt lamps are provided, but 110-volt lamps are used in the houses.

A 10-ton ice plant will be located convenient to the commissary, and a refrigerator will keep all the fresh meats in perfect condition until used. Ice will be supplied to neighboring camps at a minimum charge throughout the summer. An amusement hall, having opera chairs and seating 600 people, provides for moving-picture shows weekly.

Experiments on Explosive Dust at Pittsburg Testing Station

Experiments made at the Pittsburg testing station have shown that a charge of 1¼ lb. of black powder is capable of igniting 60- to 80- or 80- to 100-mesh coal dust and propagating an explosion. Dust larger than 60-mesh was not ignited. A 2½-lb. charge, with 2 lb. of clay tamping, ignited 60- to 80-mesh dust and propagated an explosion. Also 40- to 60-mesh dust mixed with 20- to 40-mesh was ignited, but only a partial explosion took place, although the indications were that a still larger charge of powder, with a correspondingly increased concussion and heat, would produce a complete explosion. Under mine conditions, where there is an abundance of fine dust to sustain the flame, coarser sizes of dust may be able to propagate an explosion if the shot is very large; but until further tests are made 20-mesh dust is the dividing line between fine coal and dust.

Water Purification for Collieries

Special Correspondence

A growing tendency toward the establishment of large central power plants at the coal mines and a universally increasing demand for colliery bathing facilities are both emphasizing the need of water purification at mining plants. The first of a series of articles on water-purifying processes and apparatus.

The water problem in connection with colliery work, includes not only the question of securing the most convenient or economic method of ridding the mines of this element which frequently threatens to submerge the workings and to endanger the lives of the men underground, but, especially in recent years, has come to include the question of treatment both for use in steam boilers and for bathing and cleansing purposes. Modern practice will probably render these latter phases of the subject of greater and greater importance as time goes on because of two tendencies which have become increasingly evident.

The first of these tendencies is connected with the economics of power supply. There is a steadily increasing opinion that the problem of cheap power in areas adjacent to coal mines will be solved, ultimately at least, by the institution of large electric generating stations at the collieries or as near thereto as can be conveniently arranged. The cheaper forms of coal which can not be profitably transported can then be burnt here and the steam so obtained utilized to drive electric generators supplying a distribution system which may spread over hundreds of square miles of country side. This achievement is perhaps nearer actual accomplishment than is generally supposed, and even to-day we have such a system fore-shadowed in more than one large group of collieries where a central electric-generating station supplies all the power necessary for the various operations of the plant both above and below ground and in some cases for the lighting of the adjacent villages. It needs but a simple extension of this system to usher in a new era of electric power supply.

The second tendency which was referred to above, is the growing feeling that provision for the cleanliness of the miners is absolutely necessary. In Germany, France and Belgium, extensive miners' bathing installations have been equipped, and contrast most favorably with the inefficient means formerly adopted in the miners' own cottages in order to secure an occasional bath. The influence on the health and morality of the miners in those areas where such accomodations have been provided, is stated to be considerable, and there is every probability that before long similar installations will be found at most of the collieries throughout the world where the management is of an up-to-date character.

Necessity for Pure Water

For both the purposes mentioned above, water is necessary; and furthermore, it must be of a clean and pure nature. Unfortunately, however, most of the water pumped from underground workings not only contains a large amount of solid matter in suspension, which has been acquired by its passage through the earth, but also frequently becomes impregnated with iron salts and other salts in solution, that render it unfit for direct application to either

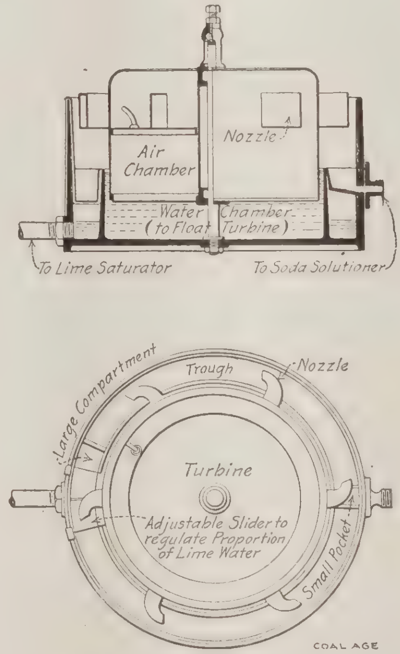


Fig. 1. Water Distributor

steam production or other purposes. It will be seen that the subject of water purification for collieries is, even at the present day, of considerable importance, and this importance will grow as time goes on. It should therefore prove a matter of interest to review briefly some of the types of water-purification apparatus which are available for special adaptation to the needs of colliery work.

It is not proposed to spend much time in this article on the question of the removal of solid matter in suspension in the water pumped from a coal mine. As a rule, such matter can be removed by means of settling tanks, into which the water is allowed to pass and rest before being drawn off for boiler or washing purposes. Where this treatment is not sufficient the water may be passed through beds of gravel or sand, which still further arrest the finer portions of suspended matter. In some cases also, the coagulating properties of aluminates are employed to bind the floating particles together into a more or less gelatinous mass; and this treatment, combined, if necessary, with a suitable filtering process is sufficient to remove the impurities that are mechanically held in the water.

By far the more serious problem, especially in the case of boiler-feed supplies, is that of getting rid of the disolved matter in the water. Fortunately, the impurities contained in solution in the majority of waters are limited to a small number of substances, and, generally speaking, the trouble which is to be most apprehended is that arising from the presence of bicarbonates of lime and magnesia (which produce what is known as temporary hardness) and from the presence of sulphates of lime and magnesia which give rise to permanent hardness, that is to say, hardness which is not removed by boiling the water.

There may also be found air and carbonic acid gas in solution, and, in the case of mine water, free acid, such as sulphurous acid, small traces of chloides and nitrates and sometimes a considerable amount of iron salts such as bicarbonate of iron. Of these the lime and magnesium salts are the most important and are the impurities with which it is most generally necessary to deal. Obviously, in the matter of boiler-feed supplies, it is advisable to get rid of the impurities before the water is allowed to enter the boiler, although the use of compounds, which deposit more or less dubious sediments in the boilers is still prevalent. The methods usually adopted for the preparation of feed water before it enters the boiler may in general be divided into two classes, the hot and the cold treatment.

The Cold Process

In order to get rid of the temporary hardness of a feed water, by chemical treatment without the use of heat, the bicarbonates are precipitated by a lime-water solution and the sulphates are precipitated by soda ash. The cold, or purely chemical treatment, usually involves a certain amount of storage capacity for the water which is being treated and it is necessary to make sure that the chemicals are added in just the proper proportion, since otherwise lime might be passed over into the

boilers, there to be deposited as scale. The cold process is particularly adapted to use where hard water must be softened before it can be used for bathing or washing purposes. It is also no less frequently adopted in connection with steam raising plants.

The alternative method of hot treatment is available where engines are being run, and consists in the employment of exhaust steam to preheat the water before it passes to the boilers.

There are numerous types of hot and cold water softeners at present installed at colliery plants and the mechanical details of some of these will be referred to in this and succeeding articles. Before passing to this, however, a preliminary reference may be made to the removal of iron compounds. In a case to be mentioned later, the mine water was discharged into a brook, and complaints were raised because of the contamination of the brook by the ochre-

water, is the addition of just the precise amount of reagent that is necessary to reduce the hardness to the required degree; and one of the chief aims in the construction of modern water softeners is to effect this admixture with as much ease and certainty as possible. As an illustration, the distributor used in the water softener made by the Harris Patent Feed Water Filter Co., Ltd., of Newcastle-upon-Tyne, may be mentioned.

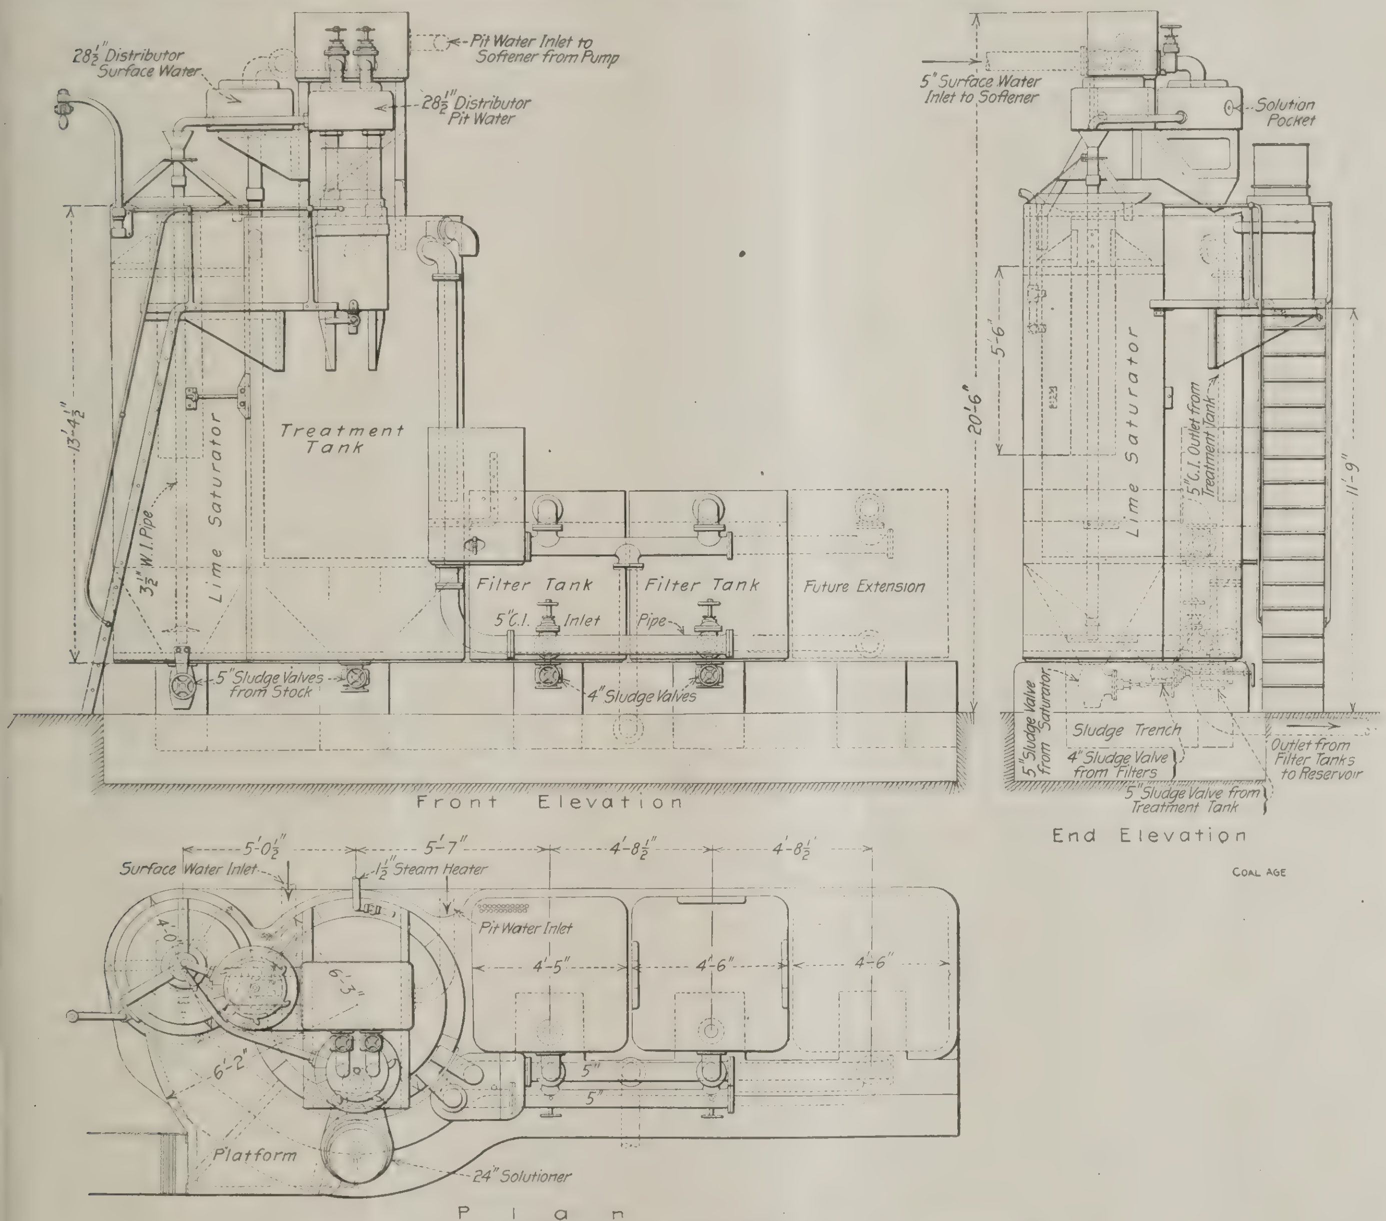

Fig. 2. Harris-Anderson Water Softener. Capacity 5000 Gal. per Hour

This heating often eliminates the necessity for the use of lime, because the temporary hardness is removed by boiling the water, and the permanent hardness is either simultaneously or subsequently treated by means of soda ash. Where exhaust steam is used in this way there is the possibility of oil being brought over from the engine, and therefore, it is not unusual to find an oil eliminating device as a part of the hot, softening process.

colored mine water. It was here necessary to install a self-cleansing filter in order to obtain a clear effluent. Still another phase of the subject is the use of colloidal aluminum, which appears, from recent investigations, to offer some promising results. This matter will be treated in further detail later on.

Harris Distributor

One of the points which demands careful attention in the treatment of

This device, shown in Fig. 1, effects an automatic and accurate separation of fractional portions of the total flow of water, the relative proportions being unaffected by changes in the rate of flow. It consists of a small turbine, floated by the water which flows into it. The water leaves by bent nozzles and thus the turbine is rotated about a vertical axis. The water flows uniformly from the nozzles into an annular trough and this trough is divided into two compart-

ments, one of which is just such a fraction of the whole trough as to correspond to the fractional part of water that it is required to separate from the main flow.

The separated portion of water is led away by a special pipe, and evidently its proportion relative to the whole is not disturbed by the total rate of flow. The water thus diverted is converted into a saturated reagent when taken to the saturator or solutioner. If saturated lime water is to be made, the amount separated is usually about one-tenth of the total flow, variation of the amount being made by the adjustment of a slide; while if caustic soda or some other strong reagent is used the proportion is much smaller, varying from one-fiftieth to one-two-hundredth part of the total. In the latter case separation is effected by means of small knife-edged pockets placed radially in the annular trough.

Where lime is used as a reagent, the water separated from the distributor passes into a conical-bottomed tank, charged with slaked lime. The water enters through the lime, thus agitating it and disolving as much as possible. From the upper part of the tank it passes out, after settling, to the reaction tank where it is mixed with the main water supply by means of baffle plates. A certain amount of sludge is separated in the reaction tank and the water is further cleared by being passed through a mechanical filter bed of wood fibre, placed either internally or externally with respect to the main tank.

Where soda or other readily soluble reagents are used, a solutioner of circular form, containing three concentric cylinders, nested in one another, is provided, as shown in Fig. 3. Successive annular spaces are thus formed. The outer containing cylinder is notched at its upper edge and leads to the delivery spout. The second cylinder is fixed so as to have its upper edge a little way above the top of the third cylinder, which latter may be adjusted vertically by means of a screw nut and is notched at its upper edge. The fourth or innermost cylinder is carried higher than all the others and is fixed. It contains a gauze cage, placed at such a height that the bottom is an inch or two below the level of the notch on the outermost cylinder. In this cage the reagent to be dissolved is placed.

Operation of Solutioner

Now, if the movable cylinder is adjusted so that its notch is slightly above that on the outer cylinder and a pipe is lead from the distributor pocket into the space between the innermost and the next cylinder, the water flowing from the pipe will pass down this annulus and up the outermost space, the water level being that of the outflowing water. The innermost cylinder will also be filled with water and this, coming into contact with the reagent, dissolves it, the resulting solution being of higher specific gravity than the water passing down the inner space to the bottom of the solutioner.

The flowing water then takes up the solution at the bottom of the tank and mixes with it, so that the outer annulus carries a solution of greater density than that in the mixing cylinder. As the overflowing solution becomes stronger the level of the water in the inflow space rises to maintain hydraulic balance and continues to rise until the solution becomes strong enough to bring the level

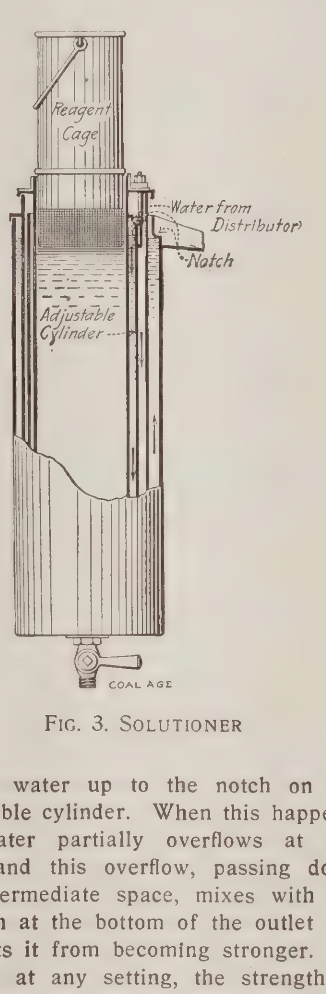

Fig. 3. Solutioner

of the water up to the notch on the adjustable cylinder. When this happens, the water partially overflows at this point and this overflow, passing down the intermediate space, mixes with the solution at the bottom of the outlet and prevents it from becoming stronger.

Thus at any setting, the strength of the outflow solution automatically adjusts itself to a constant value, and by raising the adjustable tube, the strength of the solution is raised, and by lowering it is weakened. Within working limits the strength of the solution is independent of the rate of flow through the solutioner and of the temperature of the water. Moreover, at low loads, or on standing, the increasing density of the innermost column of solution causes the height of this column to diminish and so carries the liquid out of contact with the reagent so long as the outflowing solution is of the proper strength. Waste is thus revented.

A Harris-Anderson water softener of 5000 gal. capacity is shown in Fig. 2. This is dealing successfully with water from two different sources, at a colliery in South Wales. One of the supplies is a surface water and the other is pumped from the mine. As these waters are of different strengths, two different distributors are required; one operating for the surface water and the other for the mine water. Beyond this point, however, the same apparatus deals automatically with either water supplied to it.

(To be continued)

A Combination Coal Mine

A new freak in the geology of the Rocky Mountains has recently been disclosed in the development of a mine producing anthracite, semi-anthracite and bituminous coal in addition to some coke. This rather amazing mine is owned by the Moffat Coal Co., and is located about 18 miles northwest of Steamboat Springs. The president of the company, F. M. Perry, is credited with the following statement relative to the different products of the mine:

The bituminous coal occurs at the top of the series with a semi-anthracite second and the anthracite and coke at the bottom. In common with many portions of Colorado, this district has evidently been the scene of great volcanic activities and numerous intrusive dikes are encountered. It is due to these igneous intrusions that the many different grades of coal were formed.

While these dikes ordinarily take the form of vertical fissures, it is not unusual for them to spread between the intervening strata. Under these conditions, they often have the appearance of the ordinary stratified rock and where found in Colorado are designated as "sill."

The different forms of coal can, no doubt, be easily accounted for by their proximity to these volcanic rocks. The bituminous coal at the top of the series is probably the natural form of occurrence in this region, while the change in the quality of the remainder of the seams has been caused by the different degrees of metamorphism to which they have been subjected, the coked portion representing the maximum metamorphism.

While the year 1910 saw more coke produced in the United States than ever before, the increased value was more than offset by the higher cost of the coal used. The output for 1910 was 41,681,410 short tons, valued at $99,696,267; the output for 1909 was 39,315,065 tons, valued at $89,965,483. While the increase in value was $9,730,784, there was an increase in the cost of the coal used which amounted to $12,604,732.

News of the Coal Strike Situation

Special Correspondence

No progress toward a settlement of wage agreements has been made in either anthracite or bituminous fields.

Great Britain has passed a minimum wage act which is expected to end the strike. Strikes in Germany and France have collapsed.

No definite progress toward reaching agreements between operators and min-miners has been made during the past week in either the anthracite or bituminous fields. While anthracite operators declare they are ready to discuss the miners' demands, at any time, the latter maintain that negotiations having been broken off, the first effort to renew them must come from the operators.

A week has passed since the bituminous operators and miners met in conference at Cleveland, and as yet there has been no progress toward agreement on wage scales for the states of Pennsylvania, Ohio, Indiana and Illinois.

The policy committee of the United Mine Workers met in Cleveland, Mar. 25, but deferred taking action, pending the outcome of the conference of bituminous operators and representatives of the miners. Thirty-two operators and 32 representatives of the miners constituted the full conference at Cleveland, which began Mar. 20. There were eight representatives on each side of the controversy from each of the four competitive states.

The miners presented their demands for a 10 per cent. increase in wages; a reduction in working hours from eight to seven per day, with five hours on Saturdays; provision for an unlimited "check-off"; payment on the run-of-mine basis, and weekly pay days. The operators took the same position as that taken at the first meeting of the joint-scale committee in Indianapolis last January. They contended for a 10 per cent. reduction in wages, an increase in the number of working hours and denied the balance of the miners' demands in general.

For two days, the full conference of 64 members discussed the demands of the miners and the counter proposition of the operators. Failing to agree, the whole question was referred to a subcommittee of eight operators and eight miners, constituting the joint-scale committee which reconvened at the same time that the main conference assembled.

Meeting of Joint Scale Committee

At a meeting of this subcommittee, Mar. 22, the miners again renewed their demands and the operators continued to argue for a 10 per cent. reduction in wages. Eventually, the operators suggested a continuation of the present scale for two years on condition that there would be no suspension of work at the mines under any circumstances. A vote showed the miners unanimous in their rejection of this proposition, and the subcommittee so reported back to the full conference.

Subsequently, all the several compromise offers which were made by the operators were voted down by the entire miners' representation. It being agreed, however, that a suspension of negotiations for an indefinite period would have the same effect on the industry as the declaration of a strike, it was voted to postpone further discussion until Tuesday, Mar. 26. Accordingly, the conference again met on this date, but last reports fail to show that any progress has been made toward reaching an agreement. The miners, throughout the negotiations have firmly held to the letter of their original demands. The operators have offered and withdrawn several compromise measures, without effect.

The following figures show the total number of miners employed in bituminous fields controlled by the miners' union:

Arkansas	6,000
Illinois	73,000
Indiana	22,000
Iowa	17,000
Kansas	13,000
Michigan	4,000
Missouri	10,000
Montana	4,000
Ohio	47,000
Oklahoma	9,000
Pennsylvania	82,000
Texas	4,000
Utah	3,500
Wyoming	8,000
Washington	7,000
Total	309,500

In the nonunion bituminous fields, 50,000 union miners are said to be employed. The total number of mine workers for each state in the nonunion fields is approximately as follows:

Alabama	23,000
Colorado	15,000
Kentucky	21,000
Maryland	6,000
New Mexico	4,000
Tennessee	12,000
Virginia	7,500
West Virginia	69,000
Central Pennsylvania and elsewhere	75,000
Total	232,500

The total number of mine workers in the anthracite field of Pennsylvania is approximately 175,000.

The Anthracite Controversy

In the anthracite region, independent operators, through John C. Haddock, president of the Plymouth Coal Co., have issued a statement, in which it is contended that the individual coal owners should be allowed a better price for their coal, which is taken over by the large coal-carrying companies, than that afforded by the contracts that are based on 65 per cent. of tidewater prices. It is further argued that, "the proper adjustment of this item would permit a reasonable concession to the mine workers." To this statement the larger companies, have replied by pointing out that the willingness of the independents to advance wages is based entirely upon their ability to advance prices.

The so called 65 per cent. contracts, by which the coal of the small owners has been taken over and marketed by the larger companies and coal-carrying roads, have been temporarily suspended, and for the next three months the individual operators will be permitted to dispose of their own coal at such prices as they are able to command. It is argued that this opportunity for making large profits will hold them in line with the general policies of the larger companies.

Government Intervention

Repeated rumors are current regarding the possibilities of federal intervention in an effort to avert a coal strike. While, beyond doubt, Congress and government officials at Washington are making every effort to keep well informed as to the merits and progress of the controversy, it is not likely that definite action will be taken by them prior to a demonstration of the fact that the operators and men will not be able to agree through their own efforts.

Representative Lee, of Pottsville, Penn., has proposed a bill providing for an extension of the Erdman act to apply to the coal-mining industry. The bill is at present under consideration by a committee of the House of Representatives and probably much valuable testimony will be adduced in this connection from the witnesses to be summoned. Serious objections, however, are raised against the provisions of the bill itself, in that its extension to other commodities and industries than coal and coal mining, would seem to be logical and necessary in the event of its becoming a law.

Minimum Wage Bill Passed in England

At the end of the fourth week of the British coal strike a minimum wage bill has been passed and becomes a law. This bill recognizes the principle of the minimum wage, but does not specify the amounts for which the miners have held out so long. It is therefore unlikely that the enacting of this measure will at once to settle the strike, although it will pro-

vide means by which the miners may return to work, knowing that such a minimum wage is assured them as can be agreed on in the various districts.

A week ago this bill had passed the committee stage in the House of Commons but was temporarily abandoned because the leaders of the miners' federation held out for the stipulation in the bill of the definite sums which they demand as a minimum wage; namely, 5s. a day for men and 2s. for boys employed underground. Considerable opposition to the measure had previously been manifested, and the government itself refused to incorporate any such provisions in the bill.

Conferences Were Resumed

Conferences were resumed through the intermediation of the government on Mar. 25, but were unproductive of results. The conference on the twenty-sixth was short-lived, and following it, the Premier immediately went to the House of Commons and announced that the government had put forth its best efforts to secure a settlement between operators and men, and had completely failed. The minimum-wage bill was forthwith passed by a large majority and sent to the House of Lords, which held a special session to receive it.

Some breaks in the ranks of the miners were reported during the week. One thousand men have returned to work at mines in Lanarkshire, Scotland, as well as a number at other places in Scotland and Wales. The situation in many towns is becoming more and more desperate, and it is thought the general government will have to arrange to render aid to the town treasuries in providing food for a great number of the unemployed. So far, the strike has been remarkable in its lack of violence, but it is believed that the point has now been reached where it will be difficult to hold the unemployed and suffering workers in order.

German and French Strikes Ended

Following a conference of the miners' leaders in Bochum, Mar. 19, the coal strike in Germany has come to an end. From last reports, men were returning to work in the Westphalian district at the rate of 15,000 to 20,000 a day. This strike had involved nearly 300,000 men in Westphalia, Saxony, and Lower Silesia, and was marked by disturbances of such a violent nature that troops had to be sent to the mining districts.

The strike of miners in the vicinity of Denain, France, was of short duration; the movement was in direct opposition to the wishes and councils of the miners' federation, and while it was feared for a time that it would spread to considerable proportions, it was settled without difficulty, the men returning to work, Mar. 25.

It is reported that 36,000 coal miners of Austria have demanded a 15 per cent. increase in wages, and, failing to receive this concession, have threatened to strike.

British Coal Trade Crisis

(Continued from last week)

March 8—Conferences with the committee of the Cabinet resumed. Prime Minister issued an invitation to both sides to meet at the foreign office.

March 11—The miners' conference decided that the executive of the Federation should meet in joint conference either the whole of the coal owners of Great Britain or any of the districts which are prepared to concede the principal of a minimum wage.

March 12—The coal owners agreed to accept the Prime Minister's invitation to a joint conference with the miners for a discussion of the dispute, the representatives from Scotland and South Wales doing so "without prejudice."

March 13—The miners' conference passed a resolution in which they explained they were "willing to enter into negotiations at once with the coal owners in the various districts for the purpose of securing a settlement of all points in dispute at the earliest possible moment."

March 14—Further resolutions, passed by the men's representatives, in which they "agree to the proposal of the Prime Minister that some neutral person might tend to help guide the discussion along such lines as would facilitate an agreement." This with other resolutions relieved the position of the men who, having thus conceded the arbitration point, now virtually fell into line with the suggestions made a fortnight earlier by the government.

March 15—The fourth day's sitting of the joint conference of coal owners and miners and government representatives ended disastrously, in so far that all negotiations were broken off. The Prime Minister announced that the government had done all in its power to arrive at a settlement by agreement, and that they had come to the conclusion that such was impossible. Further measures must therefore be taken and the government would ask from Parliament a legislative declaration that a reasonable minimum wage, accompanied by adequate safeguards for the protection of the employer, should be a statutory term of the contract of employment of people who are engaged underground in coal mining. Mr. Asquith indicated that the district minimum should be locally fixed by a joint board in each district consisting of representatives of employers and employees, with a neutral and independent chairman who might be selected by the parties themselves, or if necessary, by the government. In the opinion of the government such a body would afford what they have regarded as all-important — the means of securing finality.

Byproduct Coke Ovens

A list of byproduct coke ovens in the United States has several times been asked for. The following (Circular No. 97, U. S. Dept. of Agriculture) gives the list as of Jan. 1, 1910:

SEMET-SOLVAY OVENS—Solvay Process Co., Syracuse, N. Y.; Semet-Solvay Co., Pennsylvania Steel Co., Steelton, Penn., also Lebanon, Penn.; Semet-Solvay Co., National Tube Co., Benwood, W. Va.; Semet-Solvay Co., Milwaukee Coke & Gas Co., Milwaukee, Wis.; Semet-Solvay Co., Detroit, Mich., also Ensley, Ala.; By-Products Coke Corporation, South Chicago, Ill.; Semet-Solvay Co., Empire Coke Co., Geneva, N. Y.; Semet-Solvay Co., Dunbar Furnace Co., Dunbar, Penn.; Semet-Solvay Co., Central Iron & Coke Co., Tuscaloosa, Ala.; Philadelphia Suburban Gas & Electric Co., Chester, Penn.

OTTO-HOFFMANN OVENS—New England Gas & Coke Co., Everett, Mass.; Lackawanna Steel Co., Lebanon, Penn.; Dominion Tar & Chemical Co., Sydney, Nova Scotia; Hamilton-Otto Coke Co., Hamilton, Ohio. The following use both the Otto-Hoffmann and United Otto: Camden Coke Co., Camden, N. J.; Cambria Steel Co., Johnstown, Penn.

UNITED OTTO—Carnegie Steel Co., South Sharon, Penn.; Maryland Steel Co., Sparrows Point, Md.; Citizens Gas Co., Indianapolis, Ind.; Pittsburgh Gas & Coke Co., United Coke & Gas Co., Glassport, Penn.; Zenith Furnace Co., Duluth, Minn. The Lackawanna Steel Co. at its Buffalo, N. Y., plant uses both the United Otto and the Rothberg ovens.

KOPPERS—Illinois Steel Co., Joliet, Ill., and Indiana Steel Co., Gary, Ind.

Miner's Night at Pottsville, Y. M. C. A.

Over 800 miners spent Saturday night Mar. 16, as the guests of the Pottsville Y. M. C. A. There were superintendents and managers; foremen and laborers; breaker boys and helpers of every kind; men of all nationalities and degrees of learning.

The special attractions of the evening were the games in the gymnasium. These were witnessed by an audience that taxed every part of the large room.

The opening number was a series of games of volley ball between the business men and senior class men from the association. The second attraction was a game of basket ball between teams picked from the best men in the Association league. The last game had great interest for the visitors, as it was played by men from the collieries. It was a game of indoor base ball, one side captained by Potts, with men from Supt. Kaercher's district; and the other side captained by Mader, with men from Supt. Hadesty's district. It was a fast game and the men, although new to it, showed great proficiency. Potts' team won by a score of 15 to 9.

The Problem of Mine Timbering

By R. B. Woodworth*

The use of steel in the mines is discussed with regard to the proper commercial forms for certain classes of work, general methods of design and the cost of manufacture and installation. This is the fourth of a series of articles on mine timbering.

*Engineer with the Carnegie Steel Co., Pittsburg, Penn.

Note—Paper read before the Kentucky Mining Institute, Lexington, Ky., Dec. 11, 1911.

From a theoretical point of view, structural steel is the best all around material for use in mine timbering. However, the steel mills roll this material in a mulptiplicity of shapes and experience has to tell us which shapes may be used most economically, as well as whether or not the use of these shapes has solved the timbering problem to the satisfaction of the principles of scientific management.

For obvious reasons, rails were the first form of steel to be used in the mines for roof supports; and they were so used in the mines of Commentry, France, as far back as 1878. They have often been used in the mines of this country as plain bars; and I have seen them fabricated into gangway supports in the Chapin mine of the Oliver Iron Mining Co., at Iron Mountain, Mich. They have been used also as stuttles between the steel ring sets of rectagular shafts in the iron-mining districts of Minnesota and Michigan. Rails are of small depth and consequent low efficency pound for pound of material used. Owing to high carbon content, they also break easily. In the Commentry Mines they were displaced by rectangular iron bars 3.15 in. deep by 1.18 in. thick and 12 ft. long. These had the requisite vertical strength, were easily straightened, and in 1889 some of them had been re-used 200 times. Bars, however, are weak transversely and fail by sidewise deflection under compressive stress in the top fibers long before the real strength of the material is fully developed.

Long experience indicates that where cross bending stresses have to be resited, as in roof supports or in the collar of the three-piece gangway set, no form of section is more economical than the standard I-beam, which combines a high degree of resistance to bending and sufficient resistance to lateral deflection, with a minimum weight of metal. The I-beam is not, however, the best section to use for props, the legs of gangway supports, buntons and compartment dividers in shaft framing, wall plates in rectangular shaft sets or for any member that has to take pure compression or combined compression and cross bending, because the beams least radius of gyration is low and there is here required a shape that is equally strong about both axes of symmetry.

Hollow tubes possess the quality of equal strength in all directions in a theoretically ideal manner but suffer from the disadvantages of their relatively high cost of manufacture and the practical difficulties attendant upon fabrication. While hollow tubes, therefore may economically be used for props, as they have been, especially in the collapsible form, they are not adapted to the other more varied uses in frames.

Properties of the H Section

The ideal section of sufficient strength for most mine-timber framing conditions is the H-beam. This form of rolled shape possesses a large radius of gyration and, in comparison with its weight, the most economical distribution of material to resist pure compression or combined stresses. A distinct advance in the use of metal for mine timbering in England, was inaugurated by the rolling of an H section in 1885 by the Darlington Iron and Steel Co. A like impetus to the use of steel in the mines of the United States was given in 1907 when, after careful investigation of the mine timber situation, the Carnegie Steel Co. began to roll 4, 5, 6 and 8 in. H-beams with especial reference to the needs of the mines.

As early as April 7th, 1894, the Carnegie Company had called attention to the theoretical economic advantages that would follow the application of steel to mine timbering. The timber situation, however, was not then so critical as now and neither had it been shown that the use of wood in many cases entails large economic wastes. The favor with which these sections have since been received and the success which has attended their use has demonstrated their peculiar fitness for this work. Industrial progress often waits upon the proper solution of its problems and the exact satisfaction of its fundamental needs.

The H-beam is, therefore, the proper shape to use for the legs of the three-piece gangway supports, the wall plates of rectangular shaft sets, for buntons in all types of shaft framing, whether circular, elliptical or rectangular, for

mine props and for mud sills under gangway supports in swelling ground. It has also been used for cage guides both with and without cast steel safety racks. In rectangular shaft framing its broad bearing surfaces render wedging simple and secure.

The rolled steel angle makes an ideal stuttle, calculated to take either tension or compression—tension when the framing hangs from the bearers above, compression when the weight of the framing is carried to the bearers below. Its use obviates the need of hanging rods during the process of sinking. The angle also makes an efficient leg in a gangway support when the loads are light, or if desired, the rolled steel tee may be used for this purpose.

Lagging, if of metal, may be made of boiler plate (used in England as far back as 1886) corrugated sheets or, where extreme strength is needed, of buckle plates. The thin concrete slab, however, may well be used where acid water is present, either plain, or reinforced with expanded metal, wire mesh, or rods.

In repairing the rectangular shaft at the Mt. Lookout colliery of the Temple Iron Co. near Wilkes-Barre, Penn. in 1907, a steel lining was carried 50 ft. to rock, and made of 12 in. steel channels placed edge to edge. A similar lining was used in 1894 between two levels at the Grimsby Iron Ore Mine in the Siegen District, Prussia. Such a lining is not beyond right reason even in circular or elliptical shafts. In fact, circular steel segments, exact duplicates of the cast iron circular segments, were installed in an experimental way in one of the tunnels of the Hudson and Manhattan Railway, Jersey City, N. J., in 1909. Structurally the subaqueous tunnel and the circular shaft are identical and there is no economic reason why English or German tubbing should not be replaced by circular steel segments made of channels or built up of boiler plate webs and angle iron ribs, the thickness of the webs and ribs increasing with the depth of the shaft if necessary.

If boiler plate may be economically used in a tank many feet high to keep water in, it may, on a parity of reasoning, be used in a shaft many feet deep to keep water out, the stresses being the same and their effects on the lining alike. Indeed, at the Detroit River Tunnel of the Lake Shore and Michigan Southern Ry., completed in 1910, the shore approaches were made of circular cast iron segments while the portion under the river was made of twin riveted boiler plate tubes.

Cost of Fabrication

Steel beams for roof supports may be used just as they come, cut to length, from the rolling mill; all the other types of mine timbering need to be fabricated, that is, framed and fitted, before they are ready for use in the mines. A most important consideration is to reduce the cost of this fabrication to the lowest possible amount by simplification of the details. Blacksmith work always should

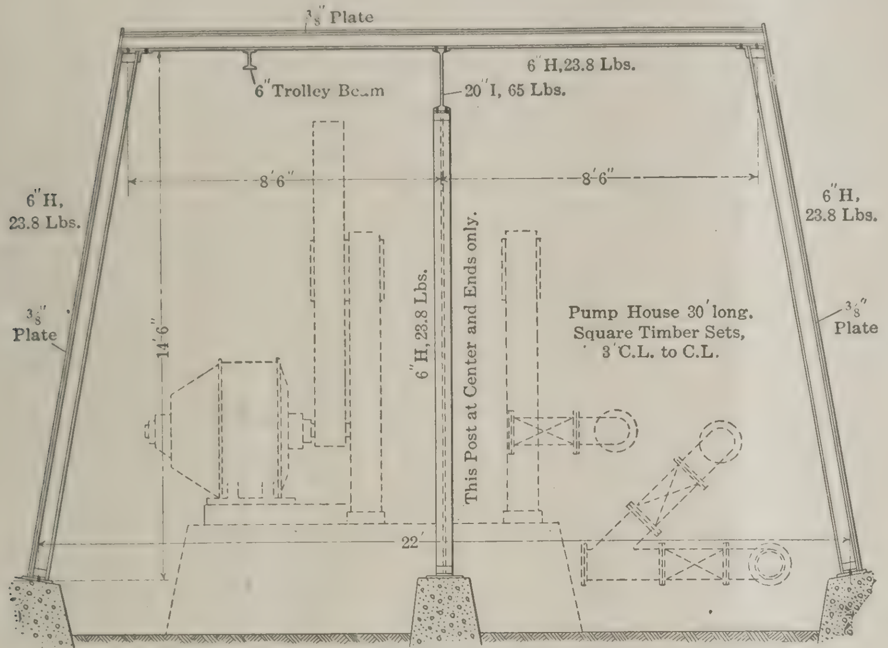
be avoided; and that form of framing is the cheapest in which the fitting shop work is the simplest. Intelligent skill in structural design here means great saving.

In my investigations, eight different types of framing for steel gangway supports have come into serious consideration. With plain material at 1.25c. per pound f.o.b. cars Pittsburgh, and the usual extras for workmanship, the comparative costs of these styles are shown in tables 1 and 2, from which can be seen at a glance how great a part attention to details may play in the economic use of materials and the avoidance of unnecessary work in fabrication. The eight sets of each table are all of equivalent theoretical strength.

The figures in these two tables do not include painting. The cost for this varies considerably with the kind of paint used but may be estimated at $2.00 per ton.



FRAMING OF STEEL TIMBER SETS FOR PUMP ROOM

Electric Lamps in Mines

The Philadelphia & Reading Coal and Iron Company leads in the use of electric mine lights. Over 500 miners in their employ are now using this type of lamp. The lamp in question, a two-volt, three candlepower construction, will burn 12 hours. It weighs only two pounds and is easily worn under mine conditions. A reflector throws the light forward, giving a good view of haulageways, roofs, chambers and the coal to be mined. By their use, difficult work, such as that required in narrow and poorly ventilated breasts, which formerly took two weeks, can now be done in three days, as the miners are free from the evil odors of open-flame lights burning in a narrow space, and in addition they have a steady, bright light to work by. The rules of the Reading company demand the use of electric lights around all breakers, mine stables or other buildings, where a spark from an open light might cause a fire.

Explosion at Sans Bois Mine No. 2

The Sans Bois mine at Chant, Oklahoma, was the seat of a severe explosion on March 20 in which 80 men were killed and 25 were rescued or escaped. Fourteen men saved themselves by breathing the air escaping from a compressed-air pump. Gas was probably the main factor in the explosion.

The Sans Bois mine No. 2 is situated at Chant, Haskell County, Okla., about 37 miles from Fort Smith, Ark., this latter city being quite close to the state line. The village of Chant is reached by the Fort Smith & Western R.R., and has a population of about 1200 inhabitants.

Use of Explosives

Though the largest of the three mines belonging to the Sans Bois Coal Co., it is not a big producer. In the fiscal year between July 1, 1909, and June 30, 1910, the output of the mine was 70,195 tons. Ninety-five miners were employed, with 57 other inside men. Adding thereto 22 men who were employed on the outside, the total force ran up to 174 men. Two significant figures are given for that year's operation; 6260 lb. of dynamite and 1045 kegs of powder were used in blasting. The proportion of slack, as might be expected, was also abnormally high. Out of 70,195 tons shipped, 35,603 tons were of pea and slack sizes. Disregarding the large amount of dynamite mentioned, nearly 2¾ lb. of powder were used per ton of coal sent to the tipple.

Presence of Firedamp

The main entry of the mine is used as a hoisting slope and the headings are turned off directly from it to the north and south. The mine, especially on the south side, has suffered from severe squeezes. For ventilating purposes a fan is provided. The mine generates firedamp and there have been two unimportant explosions before. On Dec. 30, 1909, an explosion occurred, killing an Austrian shotfirer, and within that same week, another shotfirer, this time an Italian, was killed. It was stated by the inspector that the mine was very dry and dusty after these explosions, and instructions were left that the accumulations of dust should be loaded out and the rooms and entries sprinkled before resuming operations. Both the little explosions referred to were alleged to have originated from blown-out shots.

It is customary to sprinkle the headings and it appears that water pipes were laid for that purpose. Yet, in the year before the explosions just referred to, one complaint was made of the need for sprinkling. To mining men in other states, not so strict as Oklahoma in this matter, it might be interesting to call attention to recommendations made in May, 1909, to the effect that the company was employing more than 45 men in one air current. The company was urged to build a new overcast, that the danger resulting from having so many men in one split might be reduced.

The Explosion

The explosion occurred on Mar. 20, at 9:05 a.m., probably in the entry known as the Ninth level. About 105 men were then underground. Eleven of these escaped by a manway, located about 200 yd. from the entrance. Of these, nine, who were working in the South Fifth level, did not hear the report, but the dense smoke which soon reached them gave them warning that an explosion had occurred. They immediately made their way out. One man, who later staggered to the drift mouth unaided, was walking in an entry when the explosion took place. Hearing the sound, he leapt into a disused room, and the fiery blast passed by him. Another man, a "rope rider," was on a trip of cars when the explosion occurred. Fortunately, that trip was leaving the mine, and the man came safely to the surface.

The Tipple and Drift Mouth Sans Bois Mine No. 2 at Chant, Okla.

The Rescued

The work of rescuing began at once, and a boy named John Golivas was the first one to be brought out. It was thought at that time that everyone still

remaining in the mine was dead, so complete was the demolition of the mine workings. But about noon of the following day, 25 hours after the explosion occurred, tappings were heard on a pipe line. Fourteen men were found huddled in a little pump hole, measuring 8x10 ft. They had been thoughtful enough to gather around a water pump, which was driven by air, the flow of which had not been cut off by the explosion. To shield themselves from the foul air of the entries, they had hung a curtain over the mouth of the pump hole. They removed the valve covers from the top of the pump and were piled over one another in the endeavor to breathe in as much as possible of its life-saving air. As one man after another grew faint, his fellows held him over the top of the pump until he was revived by the fresh air driven into the mine by the compressor.

To add to the difficulties of the terrible situation, the water rose in the pump hole and lay, it is said, 6 in. deep all over the floor. It is possible that the presence of the water in this part of the mine reduced the destructive action of the explosion and served later by its absorptive qualities to purify the foul air.

Despite his precarious condition and the certain perils to which exploration would expose him, one man made two unsuccessful trips to try and rescue his brother, each time dragging back a lifeless man. He was so overcome by his exertions in the foul air that when he was rescued he, with three others, had to be carried out.

Eighty Men Are Killed

The fourteen men rescued, together with the eleven men who escaped, make up the quota of men who returned alive from Wednesday's work in mine No. 2. Eighty men are believed to have perished, and 69 bodies have already been taken out. However, one of the 14 rescued from the pump room, a boy of 16 years of age, who was of the surveying corps of W. D. Roper, died after reaching the surface. At first he was partially insensible. His senses returned and he related his experiences, but suddenly a pallor spread over his face and before he could be seized he fell heavily to the ground. The shock had been too severe for him to withstand.

John Kokoski and Frank Scott were the first men who reached the pump hole, and at first they fought for the air. But gradually more noble impulses prevailed and they left their place of security to hunt for other men, that they might give up to them a part of that air which might well have proved insufficient for themselves.

Among those killed was W. D. Roper, a surveyor, of Cleo, N. C., formerly a professor in a Georgia military academy and much respected in that section. The men killed were of various nationalities, American, Austrian and Italian. The chief inspector, E. Boyle, it is said, declared that the explosion resulted from gas, and that dust did not do much to augment its force and also that insufficient care was taken to prevent an explosion.

The Waiting Crowd at the Drift Mouth

Water-Tight Shaft Lining

An English method obtaining practically dry shafts consists in using cast-iron tubbing, the insertion of which forms a water-tight lining through the water-bearing strata. This holds back the feeders of water and provides against permanent pumping.

The tubbing consists of segments, cast to suit the circumference of the shaft and the pressure to which it is to be subjected. Usually 8 to 12 segments 4 ft. long and 18 to 36 in. deep are used. The smooth face of the segments forms the outside of the shaft and their inside face is strengthened with ribs or flanges. Each segment has at least one hole to allow the water and air to escape from behind while it is being driven into position. The thickness of such tubbing depends upon the diameter of the shaft and the vertical head; the head is usually reckoned as being equal to the depth of the shaft.

When tubbing is to be used, the shaft is put down until a good foundation is reached. Then a curb bed is prepared by hand; no blasting is done as it might disturb the bed and render it useless. After the curb bed has been carefully tested with a spirit level, a thin layer of tarred sheeting or tarred flannel is spread over it to act as a cushion between the curb and rock; the curb is then laid and fitted together with deal-sheeting between each point.

Wedges of dry yellow pine, with the grain vertical, are then driven down behind the curb until the space between the rock and the curb is filled. Harder, and thinner, oak wedges are then driven into all crevices in the pack until it is impossible to drive more; steel wedges are then driven into the pack, and in the spaces thus created, more hard-wood wedges are driven.

It is absolutely necessary that the curb be exactly level and that the exact center of the curb and shaft coincide. After the curbing is set and wedged into position, layers of elm, fir or deal-sheeting are placed on top and the segments of tubbing lowered and wedged into position. Any space between the shaft and the tubbing is filled with concrete for the first few rings, puddled clay being used for the remainder.

After one ring of tubbing has been wedged up, a layer of sheeting is placed on the top flange and the next ring laid. The vertical joints are wedged first, beginning at the bottom and working up, and the horizontal joints wedged last. When the wedging is finished, the hole made in each segment for the escape of air and water is stopped with a wooden plug driven in tight. A relief valve is located in the top ring of the tubbing to allow the air to escape so that the plates will not be forced out of position.

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

Few men in the coal industry of this country have advanced to a position of high responsibility with such rapidity as has Carl Scholz. Born in Germany 40 years ago, his early education was obtained in the private schools of the Duke of Hohenlohe, at Slaventzitz, where he spent six years.

This early education was succeeded by two years of training under Professor Schmiedcke in the upper Silesian Mining School at Tarnowitz; following this, Mr. Scholz worked two years at the mines, partly as a practical miner, and the remainder of the time in the laboratories and offices, always under the direction of the mining school.

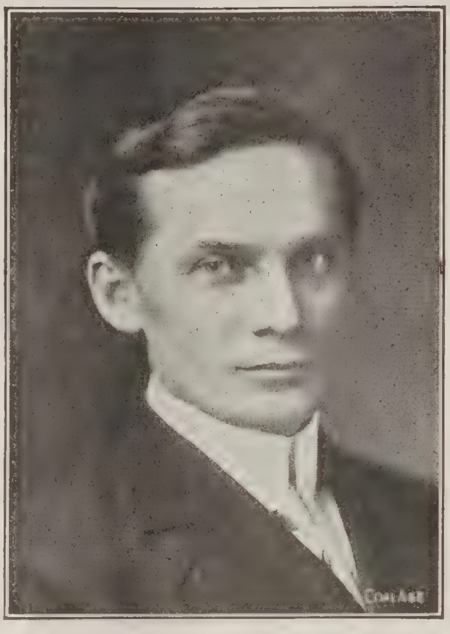
Perhaps it was his German training, administered with military precision, or probably the cause is an inherited racial characteristic, but the fact remains that Carl Scholz is 110 per cent. efficient in the matter of observing details. If each man possesses some special ability that is a key to the door of success, then a keenness for small essentials is the pass that slipped the lock for Carl.

There's any number of systems for accounting costs of mining, but few coal companies have skeleton forms superior to those adopted by Mr. Scholz. And right here let me say that his policy is to spend more than the average amount of money on the preparation of fortnightly operation charge sheets, and economize, if necessary, on some less important work. Each superintendent, therefore, is always informed where leaks exist and where attention is needed.

When Carl Scholz first came to this country, he secured employment as assistant mining engineer with the Mount Carbon Company at Powellton, W. Va. Subsequently, a partnership was formed between Mr. Scholz and James R. Thomas, the latter well known at Charleston, W. Va. Together they opened up a number of mines, being among the first to sink shafts in certain parts of the splint- and gas-coal districts of that state.

Several of these properties were afterward sold by Messrs. Thomas and Scholz to the Sunday Creek Coal Co., and in 1902, some of the men connected with the Rock Island railroad, persuaded Mr. Scholz to take up the management of its coal properties located in Oklahoma.

Gradually he became the executive in charge of all its different mining interests, until, at the present time, he is president of the Rock Island Coal Mining Company and of the Coal Valley Mining Company; vice-president of the Consolidated Indiana Coal Company and manager of the Mining Bureau of the Chicago, Rock Island & Pacific Railroad.



CARL SCHOLZ

In recent years, Carl Scholz has supplied the U. S. Geological Survey valuable information on the geology of the various sections of the country in which he is actively interested. His work as a mining engineer and scientist was well recognized by the government in 1910, when he visited the British Isles, France, Belgium and Germany, under the auspices of the Federal Bureau of Mines.

As consulting engineer for that department, his investigations were chiefly confined to a practical and scientific analysis of the foreign laws governing the operation of coal mines. Attention was paid to discipline in the mines, prevention of accidents and waste in mining, employer's liability and the German selling syndicates.

One of the hobbies of "C. S." is his advocacy of better regulated methods for selling the fuel production of our collieries. He applauds the German Syndicate system which handles the bulk of that country's output without subjecting the product to the losses and waste incurred through suicidal competition, such as has existed in our own bituminous industry. He says the German method has placed the coal industry in that country on a basis that enables the operators to mine at a reasonable profit, in consequence of which they are able to pay their employees a fair wage and to furnish better protection against injury. The coal consumer benefits through the elimination of fluctuations in price. The large user does not secure a low price at the expense of the small buyer.

When it comes to technical problems that have a direct bearing on present coal practice, our friend Carl looms brightly as a man of fixed and original ideas.

In answer to the question as to whether or not we should reverse a fan in time of distress, Carl says, "*No Never*—Not only do not reverse them, but don't even make them so they can be reversed." He would like somebody to tell him when a fan was ever reversed with beneficial results. Says he can point out dozens of instances where lives were unnecessarily sacrificed by such a maneuver. Declares that miners become creatures of habit; that they soon learn the return and intake airways, and in time of danger instinctively rush toward fresh air.

He further states that no plan is possible whereby men imprisoned underground can be notified that the system of ventilation has been changed. Says if any action at all is necessary, the fan can be stopped and this will accomplish all that is needed. In support of such opinions, Mr. Scholz is now installing only non-reversible fans, cutting his fan installation cost practically in half and in addition removing what he considers a useless danger.

In opening an immense field in Iowa, "Carl S." is putting into effect a number of ideas that are ultra-modern as coal practice in this country goes. The chief point of interest, perhaps, is his plan for using only electric hoists. He figures that the present type of steam-hoisting engine will consume on an average from 100 to 125 lb. of steam per effective horsepower; his plan for an electric hoist driven by condensing engines and including conversion losses, entails the use of only 25 lb. or steam. Thus only about 20 per cent. as much fuel is required.

As to first cost, he says the electric hoist will figure two or three times as much, but if electricity is needed for other purposes and a central power station is built, the saving that will result almost immediately will reimburse for the higher initial expenditure. He states the advantages of electric hoisting as, better control, greater safety, economy in steam consumption, lower maintenance charges and reduction in space required.

COAL AGE

The Labor Situation

There has been no change in the anthracite-coal controversy, and up to the present time the bituminous operators and labor leaders who are in conference in Cleveland have not reached an agreement. The chief development of the past few days is the weak and faltering policy of the bituminous operators. At the commencement of the present negotiations, the soft-coal mine owners had an excellent case, and there was every reason to anticipate that a favorable compromise would be reached with the union miners. Whether it is leadership or what not, the bituminous operators have receded from their position a half dozen times in less than that number of days.

In direct contrast to the action of the soft-coal men was the conduct of the anthracite operators in their meeting with the miners' leaders. There was no irresolution or unsteadiness of purpose when the hard-coal people met Mr. White and his lieutenants in New York. The miners did not smile and leave town filled with the idea that they controlled the outcome of the situation. They know now that whatever concessions they win in the anthracite field will come after a struggle that will test both their strength and the merits of their demands.

At Cleveland, the representatives of the bituminous mine owners started by first conceding the elimination of their demand for a 10 per cent. reduction in wages. Other backdowns followed in rapid succession and this action as a whole was supplemented by dissension within their own ranks. It is probable that Illinois as usual will be the goat when an agreement is reached.

It almost seems as though the hands of fate were busy shaping the course of events to suit the wishes of the mine workers. The latter started with slight prospect of forcing their demands to a successful conclusion. All economic conditions were against them; their finances were low, 90 per cent. of the hard-coal workers opposed the strike and 75 per cent. of the miners in the bituminous fields were adverse to a shutdown. A strong bluff constituted about all the artillery the miners possessed. It now appears the soft-coal operators did not have even that strong a hand to play.

The railroads of the country consume a lot of coal, and the bituminous operators, because of their strenuous efforts to obtain rate reductions, are not on any too friendly terms with the soft-coal carrying roads. Probably these same operators realize that the railroads will seriously oppose any advance in the price of the coal they purchase at the present time, when they have just been compelled to concede material reductions in their carrying charges. If the operators can have it appear that any advance they give has been forced by the miners, aided in their fight by public opinion, then, so the coal owners figure, a better face will be put on the entire matter and consumers will be more likely to stand for a raise in the price of coal.

The situation in the anthracite field, however, does not promise so well for the miners' side of the controversy. And it is in this district particularly that the union wants to strengthen its position. The only recognition given them by the hard-coal operators is comprised entirely in the action of the conciliation board, which commission was created to settle disputes between the employers and the men. There is absolutely no hope of the union leaders securing any further recognition here, whether it is in the form of a "check-off" system or any other principle that would bring about the same result.

The situation, therefore, with the exception of the change in the front of the soft-coal owners, remains practically the same as when the negotiations first started. The outlook is for a settlement in the bituminous states, perhaps after a short suspension, with possibly a slight advance in wages (probably 5c. per ton) awarded the miners. In the anthracite field the chances are for a suspension, the outcome of which it is difficult to prophesy.

There is little doubt but that the hard-coal owners will try to break the strike shortly after a suspension occurs. The employers know of the feeling that exists among the miners and they will take advantage of this desire on the part of their employees to remain at work. The operators can point to the prosperity that has resulted in northeastern Pennsylvania from a cessation of serious labor disputes. The men themselves realize better than anybody else that they are not the overworked, underpaid class of employees that some writers would have us believe.

It is therefore quite probable the miners will lose in their struggle and it is possible the suspension will not be as long extended as many of us at first believed. The threatened danger, however, may not end with the demolition of the United Mine Workers of America in the anthracite industry. There is another great industrial organization of workers that is planning and would be greatly pleased to see the union of the mine employees destroyed. The federation I refer to is closely allied, in fact it is really a part of a certain political party, and if the campaign as outlined by the labor leaders who are opposed to the present mine workers' organization, can be carried to a successful conclusion, a second strike fostered and financed by a body of men who have just come out of a winning fight in another industry, will be precipitated several weeks prior to the November elections, and before a normal supply of coal can be restored.

The chief difficulty to the consummation of any such comprehensive plan will be found in the attitude of the more intelligent class of miners working in the northern anthracite field. These men, mostly Welsh and generally of a high order of intelligence and efficiency, are already supporters of the old political parties and are not so easily led by radical socialistic propaganda.

Without in any way attempting to assume the position of an alarmist, we do believe the situation bears watching, and it is likely the outcome may differ a little from what many of us anticipate. There is an undercurrent of thought prevalent today wherever men work with their hands, and history has shown that oftentimes a monster structure has arisen from the ruins of some smaller and less imposing edifice. It is a question whether the miners' union should be destroyed even if such a result can be effected.

The Technical Graduate

Gradually the technical graduate is working his way toward the reconstruction of the mining industry. Years ago, when the so called practical man filled every important official position, any devices requiring technical training for installation or operating were ruthlessly denounced. They had been built, installed, operated and supervised by the inexpert and had naturally been found grievously wanting. Today developments in every line have made the graduate indispensable. His future as director of the industry is no longer in doubt.

Unfortunately, there is some good ground for abuse of the graduate, viewed as that raw product emerges from the mill. We do not refer to his overweening confidence, his arrogance, his inability to learn from the evidences of his eyes, his proneness to discount all wisdom save that proclaimed from cap and gown, his lack of the mellowing influences of experience, or even to his contemptuous attitude to all things mundane after a long sojourn in marble halls. These are personal faults, not subject to academic correction, but there is a more belittling fault than all of these.

The difficulty with the boy graduate arises from the failure of the average professor to score and underscore the primary essentials of academic teaching. Before the graduate has been one day on the job, he has discovered that some fact, known to every rodman or engine hostler, has evaded him. He has been taught all he needs to know about it, more, perhaps, than he will ever need to know, but this essential fact has been overlooked. All his teaching has been in double-leaded type, and he has been expected without experience to separate the essential from that which is merely valuable. He has felt that he could not carry the whole mass of information so prodigally bestowed on him, and he has chosen blindly that which his brain cells have most readily accommodated. He finds too late that his choice uncontrolled was grievously ill advised.

The graduate is thus rebuffed and put at a disadvantage at the very threshold of his career. His solution of equations of higher degree, his calculus and his stress analyses are above his critics, but this one thing, this one essential, is not possessed, and all his college training is condemned.

We think the college faculties could rectify this matter by making careful inquiry of the students as to the lack of knowledge which first confounded them. Why not ask some man of broad knowledge just what a young man should know before all else, to make a good appearance when he enters the practical life? And having such knowledge, the students in the senior year should be carefully examined and made to answer such questions unfalteringly, making absolutely no mistakes. If the student fails he can be reëxamined, coached and helped in every way so that he will enter his profession with at least the stock-in-trade of the office blueprinter, the chainman or the engine swabber.

What's In a Heading?

Even editors are occasionally imbued with feelings, and we must confess to a distinct shock to our own on reading the following head lines in the *Weekly Courier,* of Mar. 21:

U. S. MINE BUREAU HAS ITS MARTYRS

Two Trained Rescuers Have Given Up Their Lives in Action

Dr. Holmes Is Well Pleased

We believe we know Dr. Holmes well enough to emphatically deny that he is "well pleased," and we are sure we know the *Weekly Courier* well enough to anticipate its apology.

Contrary to general belief, editorial work is no sinecure, and its "rewards" are often the reverse of rewards. As the editor sits, in modest pride, reviewing the results of his labors in a current issue, his dreams are not infrequently dispelled by the receipt of a communication to the effect that "the crosscut between rooms 61 and 62 on the 32d Butt Entry off the 12th South Entry is shown slanting in the wrong direction!"

Strange as it seems, the more extraordinary errors are the ones that most frequently get through. For instance, the Associated Press once sent out a description of a gun fight in which the principals had shot each other to death. After describing all the bloody details, the dispatch concluded with, "it is believed the men had some misunderstanding."

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

The Fireboss Question

Much interest has been aroused by the discussion that has appeared in the columns of COAL AGE, relating to the work, qualifications and duties of the fireboss; and I beg to submit, in this connection, a few brief extracts from an address to firebosses and those aspiring to such position, delivered by James Home, at the semimonthly meeting of the New River Mining Institute, held at Scarboro, W. Va., Mar. 7, 1912. Mr. Home's remarks, in substance, were as follows:

In my opinion the fireboss is the chief guardian of any mine where his services are required. Some firebosses assume that their duties are merely to examine a mine for gas and note any derangement that may have taken place in the ventilation. These duties should be performed with great care, at all times. They cover, however, but a small portion of the dangerous conditions that should be detected by a keen, observant fireboss.

To reach a high standard of efficiency, the fireboss should be familiar with every circumstance occurring in the mine; and must have a thorough knowledge of all the difficulties to be encountered in the mining of coal. His judgment should be sound and he must have the courage of his own convictions. He should consult himself often concerning what action he would take in the event of a sudden outburst of gas, stoppage of the fan, choking of the airways by falls of roof or inflow of water, fire in any part of the mine, etc. Such a rehearsal of his actions beforehand is essential to make him cool headed and ready for action even if the process is only mentally performed. He would in all probability be able to employ some of the plans thus formed, when confronted with the real thing. While in the performance of his duties, he should be possessed of a feeling such as takes hold of the hunter when he enters the forest. The difference between them is, that the hunter is seized with a desire to destroy life, and in order to satisfy that desire he searches for a trace of any living thing, which he hopes to kill. The fireboss should be as deeply interested in his desire to save life and to discover any conditions that are dangerous, for the purpose of counteracting them and making the mine safe. I am sure there is as much inspiration to be found in the one as in the other.

Let us travel with the fireboss and see what are his duties. Arriving at the mine, three hours prior to the time of starting the shift, he carefully examines, fills and adjusts his safety lamp, visits the fan, makes a note of the water-gage barometer and thermometer readings, passes through the boiler and engine rooms, speaking to the fireman and engineer. If all is well, he erases the report on the bulletin board affixing the date of the present day, after which he descends into the mine. The absence of the O. K. on the board together with the instructions given the engineer and the locking of the travelingway gate will suffice to keep any unauthorized person from entering the mine until his return. He observes the condition of the shaft while slowly descending, and upon reaching the shaft bottom goes to the foot of the downcast to see if the usual volume of air is traveling in its proper course. Finding all satisfactory he proceeds into the mine, traveling with the intake air current, for the reason that should he encounter a mine fire or a large body of gas he has only to retreat a few steps to safety. Whereas were he approaching from the return side, his retreat from the danger zone would be less easily accomplished. As he advances, he examines all cavities in the roof, entrances to abandoned workings, and void places where gas would be likely to lodge and sees that all danger signals are in place. On arriving at the working face he observes the conditions there in detail, for it is here that 80 per cent. of the accidents occur. He not only examines each place for explosive gas, loose rock or coal, absence of timber or condition of the timbering, but he is observant to detect any dangerous practices on the part of miners in the manner of placing their shots, securing the roof and coal, and the general care taken of their working places. More lives have been sacrificed in coal mining through the indifference of mine officials to these last-mentioned dangers than from all other causes combined.

It may be asked how the fireboss is to detect these dangers while the miner is not actually engaged at his work. It is easy for any experienced fireboss to distinguish the difference between a prudent and careful miner's place where everything is neat and orderly, and the scene of disorder that prevails in a place worked by an ignorant or a careless miner. Holes drilled too deep, the absence of stemming material, huge lumps of coal thrown back 50 ft. from the face by the force of the blast, and the general ragged appearance of everything in the vicinity tell an unmistakable tale.

After examining each place in its turn for the dangers mentioned, and marking the date of inspection near the face, as evidence of his presence, the fireboss returns by the haulways, inspecting on his way the wiring and general condition of roof and the timbering and track. Having fenced off all unsafe places found and from which he was unable to remove the danger at the time, he ascends the shaft, makes a written report in the book kept for that purpose and marks the bulletin as it should be, O. K. or otherwise. It is the duty of the fireboss also to warn any man in whose place he has discovered any danger, and to make a verbal report to the mine foreman and stand ready to carry out that officials orders, during the remaining hours he is on duty.

One Who Has Firebossed.

Whipple, W. Va.

Normal Ventilation at Firing Time

I have read, with much interest, the letter of John Verner in the issue of Feb. 3. He draws attention to the fact that, where the workings have extended a considerable distance underground, mine explosions are less frequent than when mining is first commenced. This is an interesting conclusion, though Mr. Verner does not say emphatically that this extension of the workings is the sole cause of the reduction in the number of explosions. Yet he leads the reader to the inference that the ventilating current should be reduced in volume when shots are being fired.

The reductions in the quantity of moving air, in the cases Mr. Verner instances were not intentional but were caused by the extension of the mine workings without a corresponding increase in the volume of the air entering the mines. Of course, it is a natural consequence, that the air current is retarded when it meets with the extra friction of the lengthened airways. Nor is it less axiomatic that this will result in a slower feeding of the coal dust to the flame of an explosion. However, we should not forget that these considerations have solely to

do with the extension of the violence and have no influence on the primary ignition or explosion.

I am a strong advocate of fresh air, the more the better, within reason. Moreover, in the mines of Pennsylvania, if the fan is stopped or slowed down, the legal quantity of air will not be circulating. The law also requires the continuous operation of the fans or ventilators at a certain speed in accordance with a notice posted by the mine foreman. By this, with the approval of the mine inspector, the fan engineer must be guided. So there seems in the law of the state no provision made for variable air circulation.

The Results of Low Velocity

The velocity of the air is gaged to meet the normal requirements of the mine and unless the shots are fired after all the men have left the mine, the air will soon become cloudy and thick from the burning of the mine lamps and the breathing of the mules and men. Slowing a fan increases the danger. Doors are kept closed partly by the ventilating pressure existing when the fan is in operation. When this ventilating pressure is reduced a violent blast may partially open a door and in any event the door will be less forcibly closed and may pass what little air is flowing. When the fan is passing a small air current, regulators do not permit the same proportions of air to pass as they do when the air is normal. Thus the current is likely to be cut off some sections of the mine. If the fan is not merely slowed but stopped, natural ventilation may cause a reversal of the current. Such changes would be likely to make conditions ideal for explosions.

By decreasing the amount of air, we increase the gas present in the mine because while the evolution of gas continues constant, there is less air to dilute it and the gas is less rapidly removed from the mine. Hence by stopping or slowing the fan, we increase the percentage of the gas present and if we follow that reduction of ventilation by firing a number of shots, we arrange to have a dangerous condition of the atmosphere at the most critical period of the day's work.

Dangers of a Low Velocity

I am of the opinion that slowing the fan increases the dangers inherent to firing shots. When the current slows down the suspended dust is deposited on all exposed surfaces. When other shots are fired, a new accession of dust is created and this is also deposited. Had the current remained as strong as before, the dust already in suspension and that which is derived from the shotfiring would in turn have been swept out of the mine.

As a matter of precaution, we should keep all the dust we can loaded out. We should wet the faces and sides thoroughly near shot holes. All shots in any one working place should be fired simultaneously and the firing should commence at the end of the airway nearest the upcast or return entry.

Timber Framing for Heavy Side Pressures

Replying to the criticism offered by Mine Superintendent, Johnstown, Penn., as published in Coal Age, Feb. 24, page 651, permit me to say I am quite sure his method of timbering, as there shown, is all right for strength. I have used similar methods many times; but, in answering the original question, I had in mind a heading or drift where the room was limited. The method proposed by my critic would take up 2 or 3 ft. of space, which with the ever increasing size of the mine car would hardly be permissible.

Furthermore, "Mine Superintendent" has failed to read my statement correctly. He assumes that I suggested setting the post at an angle of 45 deg. from the perpendicular in order to support a side pressure. I suggested, in Coal Age, Jan. 20, page 490, that the cap should be cut at 45 deg. and the leg cut the same plus the batter. The batter of a post in a drift is generally 2 in. to the foot, sometimes less.

My critic will pardon me for stating that he is mistaken when he says, I would not get strength from the corner brace. If this is properly spiked and fitted to the timber frame, it would shorten the leg, and, from memory, I think the strength of a piece of timber is inversely as its length.

Drilling the Mine Floor

In your issue of Feb. 17, I notice an inquiry of an "Anxious Foreman," regarding "Cross Bar Timbering."

The method of support you suggest is O. K., but, if the pillars are not large enough, it will cause the floor of the mine to heave. I would suggest that "Anxious Foreman" should have holes drilled in the floor every 4 to 6 ft. along the entry to a depth of 3 or 4 ft., thus giving room for expansion. In fact, I think the longwall method of working would suit the conditions of the mine mentioned, better than room-and-pillar, as "Anxious Foreman" has 10 in. of draw slate available for packing. I have seen places driven wide under like conditions, which stood better than the narrow places.

Marion, Ill.

Handling Material Excavated in Sinking Small Air Shafts

A novel method of sinking the small air shafts used in ventilating the lignite mines, at Hoyt, Wood County, Tex., was introduced in 1906, which reduced the cost of this work more than 50 per cent. This lignite lies at an average depth of 34 ft., under a cover of sand and clay, which in dry weather will stand in the shafts for weeks without caving. When the mines were first opened, fans were used for ventilating; but with the progress of mining and the drawing of the pillars, openings and cracks extended to the surface and much air was lost and the ventilation thereby weakened. In time, the fans were discarded and air shafts usually 4½x4½ ft. were sunk at suitable points in the mine and small brick furnaces installed to afford ventilation.

It occurred to the writer, in charge of the work, that if the dirt excavated from these shafts could be dropped into the mine through a drill hole in place of being loaded and hoisted in buckets, both time and money would be saved. This method was tried and proved so satisfactory that it was used afterward wherever possible. The general method of procedure was as follows:

After determining the location of the shaft underground, usually in a room-neck or in an opening driven especially for the purpose, a line was run to locate the point on the surface, and a 12-in. drill hole put down into the mine, at a cost of 20c. per ft. Two men, alternating each other in the shaft, and furnished with a couple of chisel-end picks, a short breast auger, tamping stick, dynamite and a tripod or windlass and rope, could sink 6 to 8 ft. per day, in ordinary ground. In damp ground, the drill hole often clogged or closed completely, owing to the damp earth adhering to the sides, and to keep it clear a knotted rope suspended in the hole was drawn up and down at intervals. When the ground was hard, half a stick of powder, fired in a 2½-ft. hole, in each corner of the shaft, made the digging easier and did not choke the drill hole as did heavier charges in deeper holes.

A pit car standing on the mine tracks under the hole caught the dirt and was replaced when full, by the drivers, as a part of their regular work. The dirt was used to grade the roads in the mine or was hoisted and sent to the dump. All the shafts were timbered with 2-in. oak plank set edge to edge, with the ends notched to fit into each other, all being cut from a single pattern. By this method of sinking and timbering, a shaft could be sunk and timbered at a total cost of between $1.75 and $2 per ft.

The Fireboss Question, A Mine Superintendent's View

In your issue of Mar. 9, I became much interested in the discussion by the various firebosses, pages 717 to 719, because I once filled that position myself. I have filled all the positions at various times in the anthracite region from slatepicker boy to mine superintendent, which is my present position; and when I look back to the eight years I spent in the capacity of fireboss, I cannot help but feel that their work is not fully understood by the average mine operator or superintendent. As a rule, these men have not filled the position themselves, and consequently fail to fully appreciate the services of firebosses.

"Fireboss," western Pennsylvania, truly suggests that the position of fireboss is often considered an unnecessary expense that operators are compelled to endure on account of the mine law. Let me say, the fireboss, if he is conscientious and faithful in the discharge of his duties, is one of the most valuable officials connected with the operation of a mine. He must be alert and fearless. But, you may say, all that is required of him is to see that the mine is free from gas. True, that is the only requirement within the purview of the law; but let us consider some of the responsibilities that devolve upon him and the dangers to which he is exposed in the daily discharge of his duties.

First, he must visit and examine all the breasts or working places in his district, any of which may contain gas in dangerous quantities, and this examination must be made before a miner is allowed to enter the mine. Not only must he test each place for gas, but he should examine the roof to see if it is sound and in safe condition. He should observe the props or posts to see that they are properly stood and have good cap pieces over them. If there is a parting or band of rock in the center of the coal seam, or if it be the custom to undermine the coal, he should examine to see whether or not the mining is too deep and the coal properly spragged. He should also observe whether or not the chamber is supplied with sufficient props and caps, which the miner may require during the day.

Picture the dangers to which the fireboss is exposed in making the rounds of these places. Rising each morning at 2 o'clock so that he may be on time at the foot of the shaft, he prepares for his lonely walk into a dangerous mine where death may be lurking in some chamber. The distance he must travel underground to reach his work is often two and may be three miles. Arriving at the first chamber on his rounds, he lowers his light and raises his lamp slowly toward the roof, watching the flame closely for any indication of gas. If none be found he places his mark, usually the figure indicating the day of the month, in a place that can be readily seen by the miner or mine foreman on entering the chamber.

Passing on to other working places, he is constantly reminded of the danger from falling roof or gas that he is liable to meet at any time. These dangers are greater, because in making his rounds he must hurry as the three hours required by law scarcely give him time to visit all the places in his district.

I have a distinct recollection of walking into breasts and being greeted with a rush of air caused by a fall in the place I was about to enter, the concussion being of sufficient force to extinguish my light. Perhaps, in another chamber, a careless miner has left his needle lying with the point facing the crosscut, and the fireboss hurrying on barely escapes having his eye put out or being impaled on the needle as with a bayonet.

In the letters of some of the firebosses I notice a slight tone of resentment, and the fact that I lay so much stress on the difficulties and dangers of the position might suggest that I too have the same feeling; such, however, is not the case. We must remember that operators, superintendents and managers of mines have crosses to bear as well as firebosses; and if the latter are laid off in idle times possibly, in many cases, it is due to the habit of the fireboss in contenting himself with simply fulfilling the dead letter of the law without any thought of working for the interest of the company that pays him. It is by honest conscientious work that the fireboss earns the commendation of his superintendent and increases his chances of promotion. The fireboss that will do this may reasonably hope to be mine foreman or superintendent at some time in the future not far distant. He should employ all his spare time in the study of mine work and familiarize himself with the principles relating to mining. This statement may cause some amazement, but I mean that very thing. Unless a man moves forward, he is certainly moving backward. I have proved this in my own experience and if space would permit I could give many concrete illustrations to show the practical working out of this truth.

By 7 o'clock the fireboss has completed his first inspection of the mine and goes to breakfast. On his return to the mine, about 8 o'clock, he consults his notes to see what is needed and orders the timber and other material required and sees that it is prepared and sent into the mine. He is then ready for his second inspection, in which he visits the more dangerous places in the mine and attends to other matters that may be required. He advises the miner concerning the cleaning and loading of the coal, the topping of cars, the location of shots, the charging and tamping of holes. On meeting the mine foreman, in the mine, the fireboss should be able to answer intelligently all questions concerning the various places he has visited, not only with respect to the danger or safety, which is strictly his concern, but he should be able to inform the mine foreman in regard to the quantity of loose coal the miner has on hand and whether or not the majority of cars in the working places are empty or loaded. He should also be able to state whether or not work ordered the previous day has been done.

This may seem to be too great a tax on his memory, but any successful fireboss of four or five years' experience will agree that he has a vivid recollection of the exact appearance of each place visited and is able to recall without difficulty in detail the condition of each place and what is needed. He knows the name and character of each miner, his laborer, and is familiar with their peculiarities. This is not given as an instance of good memory, but to impress the fact that every fireboss worthy of the name should be able to describe the condition of each place visited.

I agree that this is not required by the mine law; but, on the other hand, it does not require nine hours of a fireboss' time to fulfill all the requirements of the law, and the remainder of his time he should devote to the interests of the company that pays him. Every fireboss is or should be ambitious for promotion to the position of mine foreman, and in time to that of superintendent; and let me add there is no person so well fitted by training, for these positions, as the fireboss providing he has improved his time and fitted himself for higher work by study and reading.

In conclusion I will say the fireboss should be one of the last men suspended during a shutdown. To gain this preference, however, he should never shirk his duties and always strive to employ his entire time to the advantage of the company for whom he is working. A fireboss to be worthy of the name should be of so much value in the operation of a mine that the mine foreman would not think of such a thing as laying him off, or doing anything that would lessen his enthusiasm in the discharge of his duties. Every fireboss has the opportunity of making his services worth far more to the company than the price paid in wages. Should he do this there would be no question of the result of his efforts when he seeks promotion, because promotion will seek and find him. Remember the Chinese proverb, "I am not concerned that I have no position; I am concerned in fitting myself for a position."

Murray, Penn. M. J. Clemons,
Superintendent.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Interesting Questions

Gas on Falls

Ques.—If in making your examination of a mine you found gas on the "falls," what would be your method of procedure and what would you recommend for safety, the mine being operated with naked lights?

Ans.—The first step to be taken to provide for the safety of the men while removing this gas will depend upon the quantity of gas accumulated and its location with respect to the ventilating current. A thorough knowledge of the surroundings and a careful estimate of the quantity of gas present is absolutely necessary before any steps are taken for its removal. All the men on the return of the current must be notified and in case the body of gas is considerable these men must be withdrawn. In case considerable gas has accumulated on the falls and it is found that the accidental explosion of the gas would communicate to a larger body of gas in some near-by abandoned workings, all the men should be withdrawn from the mine before taking any steps to remove the gas.

Having, in this manner, provided for the safety of the men, the next step is to station reliable men at each entrance or approach to the return current. Only safety lamps must be used in the work, which must be conducted from the intake side of the gas. It may be necessary to erect temporary brattices so as to deflect the air current against the roof and cause this to sweep the cavities or pockets above the falls. The work must proceed slowly, giving sufficient time for the air current to act upon the body of gas. The progress of the work must be closely watched and tests made from time to time with safety lamps. Every precaution must be taken to avoid a fresh fall of roof as far as possible. Should a fall occur the gas will be driven out upon the workmen and possibly ignited on their lamps. It is therefore necessary that all lamps be kept in a safe place and properly guarded to avoid such an occurrence.

Fire in Downcast Shaft

Ques.—In case the downcast shaft of a mine takes fire, what are the first three important things to be considered?

Ans.—(1) Notify the men at once by phone, directing that reliable messengers be sent to warn the men at the working face, in each section of the mine, and instructing them in regard to the best way of escape. (2) Short-circuit the air current at the foot of the downcast shaft by setting open the main separation doors between the intake and the return, so as to prevent the smoke and gases of the fire from entering the mine; at the same time shut down the ventilating fan. The heat of the fire will probably convert the downcast shaft into an upcast; and, if it is possible to open the doors so as to short-circuit the air current at a point further in the mine, much of the smoke will be withdrawn from the main airway, by so doing. (3) Get water on the fire as quickly as possible. As soon as the current reverses at the foot of the shaft, if it does so, it will be possible to fight the fire from below, which should be done to prevent the flame from extending into the entries in the mine.

Expansion of Air Due to Rise of Temperature and Fall of Pressure

Ques.—The temperature of the intake current in a mine is 35° F. at a point in the airway, where the anemometer gives a reading of 2820 ft. in 3 min. The airway at this point measures 8 ft. 4 in. wide and 5 ft. 9 in. high. (a) What is the quantity of air passing into the mine per minute? (b) Assuming that this mine is ventilated by an exhaust fan, what quantity of air would be passing on the return airway, at the foot of the upcast shaft, if the temperature at this point is 65° F. and the water gage gives a reading of 3.4 in.? Assume that the barometric pressure at the foot of the downcast shaft is 25.39 in. and the coal seam is practically level.

Ans.—The sectional area of this airway is $8.33 \times 5.75 = 47.9$ sq.ft. Assuming the reading of the anemometer is an average reading for the airway, the velocity of the air current is $2820 \div 3 = 940$ ft. per min. The quantity of air in circulation is then

$$Q = av = 47.9 \times 940 = 45{,}026 = \text{say } 45{,}000 \textit{ cu.ft. per min.}$$

Since the fan is exhausting, the volume of air on the return airway is expanded in two ways; namely, by the rise of temperature and the fall of pressure. The expansion due to the rise of temperature is as follows:

$$\frac{460 + 65}{460 + 35} \times 45{,}000 = 47{,}755 \textit{ cu.ft.}$$

The expansion due to the fall of pressure is as follows: It is necessary first to reduce the water-gage reading and the reading of the barometer to a pressure in pounds per square foot; thus,

Water gage,

$$3.4 + 5.2 = 17.68 \textit{ lb. per sq.ft.}$$

Barometer,

$$29.35 \times 0.4911 \times 144 = 2075.58 \textit{ lb. per sq.ft.}$$

The absolute pressure of the air in the intake is, therefore,, 2075.58 lb. per sq.ft., while that in the return is less by the pressure due to the water gage, or $2075.58 - 17.68 =$ say, 2057.9 lb. per sq.ft.

The expansion due to the fall of pressure is, therefore,

$$\frac{2075.58}{2057.9} \times 47{,}755 = 48{,}165 \textit{ cu.ft.}$$

which is the total volume of air passing on the return airway.

Relation of Water Gage to Percentage of Gas in Current

Ques.—The air current in a certain mine is charged with marsh gas to the extent of 3 per cent. when the water-gage reading is 2.5 in.; what would be the percentage of gas in the current if it became necessary to reduce the speed of the fan till the water gage gave a reading of only 1 in.?

Ans.—In any given circulation, the volume of air varies as the square root of the water gage. Also, for the same quantity of gas, the percentage varies inversely as the volume of air. Therefore, the percentage of gas in the current, in this case, will vary inversely as the square root of the water gage. In other words, the percentage ratio is equal to the square root of the inverse water-gage ratio. Or calling the required percentage of gas x, we have

$$\frac{x}{3} = \sqrt{\frac{2.5}{1}}$$

$$x = 3\sqrt{2.5} = 4.74\%$$

Calculating Quantity of Air

Ques.—If the velocity of an air current is 75 ft. per minute in an airway $6\frac{1}{2}$ x$8\frac{1}{2}$ ft., what is the quantity of air passing per minute?

Ans.—The sectional area of this airway is $6.5 \times 8.5 = 55.25$ sq.ft. Assuming the given velocity is an average velocity for the airway, the quantity of air in circulation is

$$Q = av = 55.25 \times 785 = \text{say } 40{,}000 \textit{ cu.ft. per min.}$$

Sociological Department

For the Betterment of Living Conditions in Mining Communities

A First Aid Packet

There is need for a first-aid packet, which will always be at hand when an accident occurs, will always keep its contents in good aseptic condition and which yet will be light and portable. Such an appliance appears to have been produced by W. V. Gage, a physician for the Colorado Fuel & Iron Co., stationed at Primero, Colo. It was briefly described

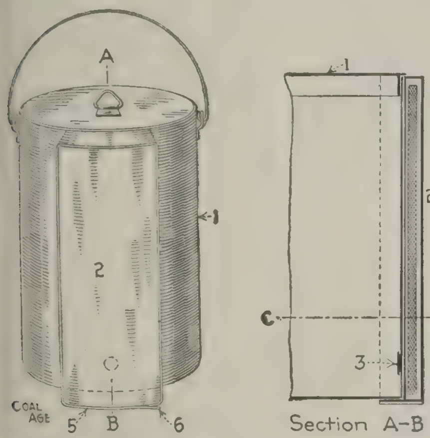

Fig. 1

Dinner Pail and Packet

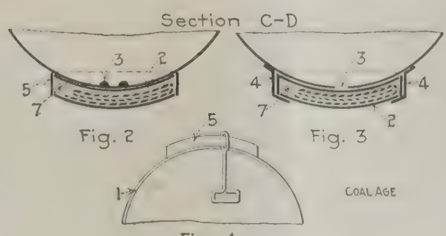
in our issue of Nov. 18 last, but will bear more extended description.

Like a Tobacco Box

The first-aid packet reminds one forcibly of those popular curved tobacco boxes, which fit the pants pocket, but in this particular instance the box is longer and narrower and fits the dinner pail. Moreover, it not only fits the pail, but is so affixed to it that the removal of the packet temporarily involves the spoiling of the dinner bucket. After the packet is removed, a new one can be affixed in its place by solder. The bucket is then as good as ever. In like manner, a packet can be torn from an old pail and soldered to the side of a new one.

An Aseptic Container

The packet being air tight remains perfectly sanitary and not subject to inleakage, even when the pail is washed and scoured. When a workingman is moved from place to place in or around a mine, his first thought is of his dinner bucket. Consequently Dr. Gates thought he could not more certainly insure that every man would carry his packet than by attaching it firmly, and, in a sense, irremovably to his dinner bucket.



Details of Packet

The packet consists of two curved pieces of tin, about 8 in. long and 3 in. wide. After picric acid gauze, a triangular bandage or whatever else may be needed has been inclosed, the two side pieces are smoothly joined by a half-inch strip of tin. Soft solder is used to make a water-tight joint. When an accident occurs demanding first-aid materials, this tin strip can be peeled off by a can opener.

In Fig. 1, the dinner pail is marked 1 and the first-aid packet is numbered 2. At 3 is shown the soldering arrangement by which the two are fastened to each other. In Fig. 2, which is a partial cross-section along the line *C D*, shown in Fig. 1, the method of attachment is made plain, though the alternative plan in Fig. 3 might be used instead. In this design, guides 4 are attached to the pail, and in these the packet 2 slides. It is, however, secured in place by a plug 3, which passes through the side of the pail. In Fig. 4, the "can opener" is shown attached to the end of the soft-tin slip 5, which has, as is shown at 6 in Fig. 1, a point of attachment at the base of the packet. A few turns of the wrist and this strip is completely withdrawn from the two curved faces of the packet.

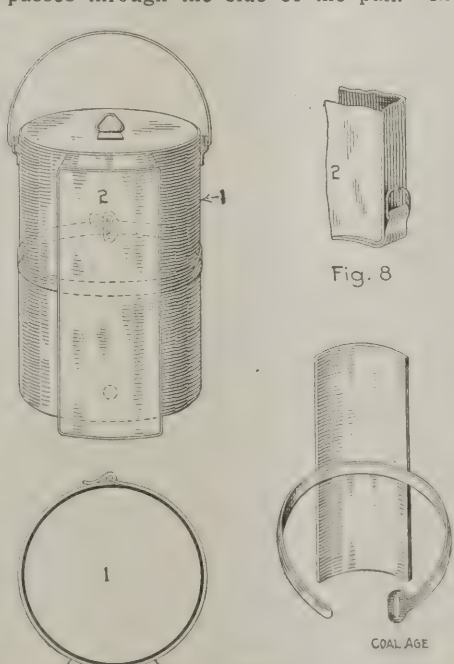


Fig. 7

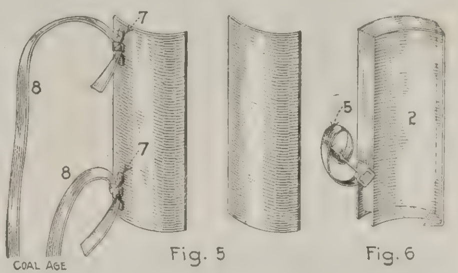
Other Modifications

The contents are permitted to drop out and two curved pieces of tin of suitable flexibility and shaped like those shown in Fig. 5 are ready for use as splints. Attached to one of these are lugs, marked 7. To these are found, already tied, strings 8, by which these strips of tin



How the Splints Are Made

can be secured as splints to the sides of any broken limb which may need their support.

Fig. 6 is another view of the same packet where the manner of removing the binding strip is more clearly shown. Another proposal is that the attachment of the pail to the packet be made by the use of a movable metal strap, as shown in Fig. 7, this strap itself being of use in providing a means whereby the splint can be affixed to the limb. Fig. 8 shows a simple method of attaching the binding strap, so that the use of the can opener can be made unnecessary. It is true that a can opener can be attached to the packet, but it is better to simplify matters by dispensing with it.

If an 8-in. splint is long enough for the support of the fractured bone, then it is certain that the scheme is one of great value, and as it assures that aseptic dressings will be always available when needed, its use is to be advocated.

Mine foremen should institute a course of prevention and cure of mine explosions, fires and accidents. All such matters should be taken up, considered, and discussed, with all the minor officials of the mine, in order that they may all be thoroughly drilled in such action as would be required in the event of a disaster.

Rescue Team in Helmets, Preparing to Enter Mine after Explosion

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

President Taft has deferred the conference which he had expected to call for the purpose of considering ways and means of preventing a coal strike. He has had several long talks, however, with Secretary Nagel and others, regarding the subject and is disposed to take such action as conditions seem to warrant when the proper time comes. At present, he is understood to feel that the facts in the case do not warrant active steps on the part of the federal government.

Action on Interstate Trade Commission Bill Improbable

Meetings of the Senate committee on interstate commerce, within the past few days, have shown conclusively that it will not be possible to secure a favorable report upon any measure such as has been asked for by various coal operators, whereby provision would be made for legalizing agreements of reasonable character among the coal operators, for the purpose of fixing prices and limiting production, or adjusting it to the demands of the market.

The committee is strongly divided upon the whole subject of anti-trust legislation, amendatory of the Sherman Act.

The Lee Bill for Coal Strike Arbitration

In a lengthy hearing, Mar. 25, before a subcommittee of the House committee on interstate and foreign commerce, to which the measure has been referred, Representatives Lee and Donohoe, both of Pennsylvania, presented arguments in favor of the Lee bill, which aims to give the federal government the right of intervention in coal controversies by an extension of the so called Erdman act. Mr. Lee spoke first, and urged the committee to report favorably on the bill, on the ground that it would effect an immense saving of money and of life if in any way strikes of a prolonged nature could be avoided. He estimated that the strike of 1902 cost the country $150,000,000, in direct loss of wages and profits as well as in sacrifices entailed upon manufacturers by reason of coal shortage.

Mr. Lee then described the Erdman act and showed how beneficial had been its operation. He enumerated the many and varied controversies in which it had been invoked and then read letters which he had received from organizations of railroad employees that are not now subject to the operation of the Erdman act, asking to be included within the scope of its provisions for arbitration. He laid stress on the fact that the act is not compulsory in its working but provides for voluntary arbitration.

Importance of the Industry

Mr. Donohoe spoke of the great importance of the coal industry of the country and said that it was such as to warrant a special mode of dealing with its difficulties. This accounted for the fact that the change requested in regard to the Erdman act was not to be extended to any other industry. He thought that strikes were more serious and had a greater tendency to become chronic in the coal business than in any other line and that they entailed more suffering.

The request was made by Mr. Lee that the committee call Charles P. Neill, commissioner of labor, John Mitchell and others closely identified with the strike of 1902, to testify as witnesses. This will probably be done.

Rates on Lake Coal from West Virginia

The Interstate Commerce Commission has handed down an important decision in the matter of the investigation and suspension of advances in rates for the transportation of coal by the Chesapeake & Ohio Ry., the Baltimore & Ohio R.R., the Norfolk & Western Ry. and the Kanawha & Michigan Ry. and their connections.

The principal findings of the commission are as follows:

1. From November, 1910, to March, 1911, defendants filed with the Commission tariffs advancing their rates upon lake coal, which is coal that originates in the West Virginia coal fields and moves, during the season of open navigation on the great lakes, to various ports on Lake Erie for transshipment by vessel beyond. Shippers protested that the proposed rates were unreasonable, and they were suspended pending investigation.

2. It appears that the Chesapeake & Ohio, Kanawha & Michigan, and Baltimore & Ohio made no showing which justifies the Commission in holding that the increased rates are just and reasonable; it is, therefore, held that these three defendants may not impose upon the traffic concerned higher rates than those in effect on Jan. 1, 1910.

3. As to the Norfolk & Western, the Commission is persuaded that the imposition of the increased rates here involved will not impose an unjust and unreasonable charge for the transportation service involved.

Alabama

Birmingham—The railroads in the Birmingham district are making preparations for a car shortage, which is already beginning to be felt, on account of the increased demand for coal.

Governor O'Neal visited Birmingham recently for the purpose of considering further the contract between the State of Alabama and the Sloss-Sheffield Steel & Iron Co., whereby the company's Flat Top mine is being worked by state convicts. The agreement is at present on a basis of 42½c. per ton of coal mined, and the governor maintains that this figure should be raised to 45c., in order to place the earnings of the convict labor on a parity with those of free labor. Failing a satisfactory adjustment of this rate and the correction of certain alleged unsanitary conditions at the Flat Top mine, the governor favors abrogating the contract.

Colorado

Colorado Springs—John T. Milliken, of St. Louis, and H. McGarry, of this city, president and manager, respectively, of the Golden Cycle Mining Co., have taken over the entire coal holdings of the Pike's Peak Coal Co. and the Central Fuel Co., both of this city, and the stock of the United Fuel Co., of Denver, formerly held by J. R. McKinnie and other local interests. Milliken & Garry are now sole owners of 1760 acres of coal land north of this city, including the Pike View mine, the largest in this section. Milliken is spending $35,000 in improvements and will double the daily output, making it 1000 tons.

Denver—The Interstate Commerce Commission recently heard arguments on the application of the Colorado Coal Traffic Association, to compel the Colorado & Southern and Denver & Rio Grande railways to adopt a new plan of car distribution for coal shipments.

Illinois

Springfield—The state mining board is in receipt of a letter announcing that all previous state records were broken recently by the three Gillespie mines of the Superior Coal Co., a subsidiary of the Northwestern railroad. The figures sent in show that the average for the six days of one week was 10,984 tons per day, and that the highest day's run was 11,522

tons. Mine No. 3 averaged 4094 tons per day for the week, and reports a total loss in time of 75 min.; 40 min. while waiting for cars and 30 min. while waiting for repairs to be made to the machinery.

Danville—It is stated here that the three Dering mines near this city, the two mines at Clinton, Ind., and the two at Sullivan, Ind., will not be operated by the Brazil Block Coal Co. after Apr. 1. The company's three-year lease on these properties expires on that date, and, it is understood, will not be renewed. Whether the Derings intend to sell the mines rather than lease them or whether the Brazil company does not care to operate them for another term of years, is not known. It is understood that the mines have been run at a good profit for the past three years.

Belleville—Nearly every coal mine in the Standard field in the vicinity of Belleville, and down as far as Marissa, is working two shifts of eight hours each, in an effort to double their capacity. The greater portion of this coal is going to the Illinois Central R.R.

Chicago—Discrimination by railroads of the Central West in the distribution of cars in favor of their own coal mines and to the detriment of other operators is to be the subject of an investigation by the Illinois Railroad and Warehouse Commission. Indiana and Kentucky state officials will assist in the inquiry. The work probably will begin immediately after the April session of the body, and may continue several weeks. It is said that the investigation will disclose that the railroad and mining interests in Illinois, Indiana, Ohio and Kentucky are as closely allied as the railroads and the steel industry in the North and East. The railroads are reputed to have almost absolute control of the best and largest producing mines of the three states, and it is alleged that they discriminate against other mine operators.

The Illinois Coal Operators' Association met here recently and appointed a committee to confer with officers of the United Mine Workers in an effort to avert the threatened strike of coal miners in Illinois, Apr. 1. Closely involved with the strike situation is the car-shortage problem. Complaints of car shortages in various districts were made by many of the operators. The effort of the mines to turn out large quantities of coal before the strike comes on has caused a great demand for cars.

Indiana

Brazil—The most important work advocated by the recent annual convention of mine workers of district No. 8, is the organizing of the coal strippers. A great deal of coal is being stripped, instead of mined, in this county at present, and common labor is used in the work. The miners now intend to organize the coal strippers so that they will receive the same wages as the miners and day men employed in and about the other mines of the district.

Bicknell—The record for a day's output from the mines in and around Bicknell was broken, Mar. 25, when 143 railroad cars were loaded, making a total shipment of 5720 tons. The miners in this section do not want a strike; they are satisfied with their present wage scale and are dreading the order to lay off.

Diamond—The Wizard mine of the Hall-Zimmerman Coal Co., located on the Central Indiana R.R.; the Schrepferman No. 8 mine and the Zeller-McClelland Block No. 3 mine, at Diamond, and the Bee Ridge Coal Co.'s mine, all in Clay County, are preparing to close down indefinitely after the suspension of work which is expected to follow the Cleveland wage-scale conference. The owners say they will not go to the expense of keeping the mines in shape for work following the suspension.

Linton—Mines on the Vandalia Branch have been under a great handicap lately because of a serious cave-in under the Vandalia R.R. tracks between Sponsler and the old Island City mine. It was impossible to get cars to or from the mines for a number of days. The cave was about 60 ft. long and immediately filled with water.

Iowa

Des Moines—The state mining department has sent out a warning. Citizens of the state are urged to lay in supplies of coal before the first of the coming month if they do not wish to be caught short during the period of suspension. The department says that the suspension will last at least 60 days, and possibly 90, or even longer.

Kentucky

Louisville—A peremptory writ of mandamus was issued, Mar. 20, by the Commerce Court against the Louisville & Nashville R.R. and the Southern Ry., to compel them to carry coal from the mines of the Stony Fork Coal Co. and the Ralston Coal Co. in Kentucky to the southeastern states. The refusal of the two railroads to transport the coal grew out of a dispute as to which should furnish the necessary cars. It was shown by the evidence that the coal companies, because of their inability to have their product transported to markets in the Southeast, were practically put out of business, as 80 per cent. of their coal was marketed in that territory.

Paducah—Anticipating a strike in the soft-coal mines, the Illinois Central is hauling large quantities of coal from western Kentucky mines to its yards in Paducah. This coal will be distributed over the system as needed in the event of a strike.

Barbourville—The Mineral Development Co., composed of Philadelphia capitalists, is preparing to begin coal and timber operations on a large scale in Letcher County. The property has been opened for development by the new Lexington & Eastern R.R., and as soon as branch lines are built a number of big coal operations will be started. A contract was recently made for the extension of a three-mile line into the Boone Fork district, and the first coal operations in that field will be started by the Pennsylvanians.

Maryland

Lonaconing—It is understood that, before long, operations will be resumed at the old Jackson mine and extensive developments undertaken at the Caledonia mines. This valuable property has always been looked upon as the greatest asset of Lonaconing. There is a large acreage of excellent coal, of easy access, in the smaller seams and it is thought that one of the most profitable enterprises of the Maryland field could be established here.

Ohio

Columbus—Operators in eastern Ohio are much gratified over the recent ruling of the Interstate Commerce Commission which grants a reduction on the lake rate from No. 8 field of 10c. per ton. This is the culmination of a fight between the operators and the railroads which has lasted for more than a year. It is an entirely different action from the one brought by the Eastern Ohio Operators' Association against the Wheeling & Lake Erie R.R., in which a rate reduction was ordered by the Ohio Railway Commission.

Cambridge—The Minnehaha & Little Kate No. 2 mines of the National Coal Co., near Cambridge, which lie about two miles apart, have been connected and in the future the two mines will be operated as a unit.

St. Clairsville—Work will be commenced next month on the opening of a new mine at Fairpoint, Belmont County, to employ about 600 men, when in full operation. The Provident Coal Co., a Cleveland corporation, recently purchased several hundred acres of coal lying along the Cleveland, Lorain & Wheeling division of the Baltimore & Ohio R.R., and will spend about $300,000 in opening and equipping the mine.

Lisbon—The Card & Presser Coal Co. recently announced that it would abandon the Klondyke coal mine which has been in operation here for a number of years. The company has leased about 300 acres of coal land four miles north of

town and will open a large commercial mine at once. It will take coal from the No. 6 vein, which runs from 4½ to 6 ft. in thickness and is of excellent quality. The property is located along the Erie tracks and the old West Pittsburg tipple will be used.

Cleveland—A conference of 32 operators and as many miners' representatives from western Pennsylvania, Ohio, Illinois and Indiana, met in Cleveland, Mar. 20, to negotiate new wage contracts for these states, if possible. Nothing decisive was accomplished, prior to adjournment Mar. 22, and the matter was left in the hands of the joint scale committee, consisting of eight operators and eight miners, two from each state. The policy committee of the United Mine Workers convened here Mar. 25.

Oklahoma

McCurtain—A disastrous explosion took place at the No. 2 mine of the Sans Bois Coal Co. near here, in the morning of Mar. 20. The cause of the explosion has not been determined. Eleven men escaped from a manway at the time of the blast; 25 have since been rescued alive, and at last reports, 69 bodies had been recovered. The number killed is reported as 80, based on a total of 116 men in the mine at the time of the explosion. Rescue work was started immediately; the local government mine-rescue car was soon on the scene and No. 4 car arrived from Iowa on Friday.

Pennsylvania

Bituminous

Dravosburg—Over 400 men employed in the Risher mine at Dravosburg quit work Mar. 20, alleging that the screens used at the mine allow too much coal to sift through to the slack pile. There has been no disturbance, the miners contenting themselves with standing about in small groups and discussing the situation. They have been complaining for some time that the screens are too large.

Indiana—The plant of the Tearing Run Coal Co., operated near Homer City for several years by J. M. Guthrie & Sons, of this place, has been leased to the Townsend Coal Co., of Philadelphia. The operation includes 300 acres of coal and the lessees agree to mine not less than 100,000 tons a year.

Du Bois—It is understood that the Cascade Coal & Coke Co. will begin at once the construction of 200 additional coke ovens at Sykesville. This will just double the capacity of the present plant.

St. Marys—The Shawmut Coal Mining Co. is building a new and larger tipple at Elbon, to accommodate its increased output at that point. Ten new houses have been erected and ten more are to be put up this summer. The Shawmut & Northern R.R. has plans for building four miles of new road between Mahoning and Mosgrove, points on the Allegheny River, and also two miles of new railroad between Tidal Branch Junction and the Allegheny. Other improvements are to be made at various points to meet the demands of larger operations.

Pittsburg—A sweeping victory was won, Mar. 19, by coal shippers from the Pittsburg district to lake ports when the Interstate Commerce Commission ordered a reduction of the rate on bituminous coal from 88c. to 78c. per ton. Advances of rates on coal from Virginia and West Virginia fields to lake ports, made by the Chesapeake & Ohio, Baltimore & Ohio and Kanawha & Michigan railways, were disapproved by the commerce commission. Advances made by the Norfolk & Western on the same traffic were approved.

Anthracite

Scranton—The Lackawanna R.R. was found guilty in the federal court, at Buffalo, Mar. 19, of violating the commodities clause of the Hepburn act and was fined $2000. The government charged that in 1909 the company shipped hay from Buffalo, N. Y., to Scranton, Penn., free of charge for the use of mules in mines owned by the company in Pennsylvania.

In a gas explosion caused, it is thought, by mine settlings, which disturbed the gas mains, nine persons were killed and two injured, early Mar. 20, in Dunmore. Two miners' families, comprising two women and seven children, were either blown to pieces in the explosion or burned in the fire that followed and destroyed three houses. More than twenty dwelling houses near the scene of the explosion were badly damaged by the concussion and the flying timbers.

Wilkes-Barre—The exodus of miners from the anthracite fields in anticipation of a suspension of work was augmented recently by the departure of 100 Slavonians from the Nanticoke region, who left here for New York. They will sail for Austria.

Shamokin—The 800 employees of the Scott shaft, owned by the Mineral Railroad & Mining Co., who went on strike Mar. 18, because the company refused to sell them pea coal, have returned to work.

Pottsville—The Pine Hill Coal Co., operated by Scranton capitalists, and located at Minersville, near here, posted a notice Mar. 19, announcing that the employees will be granted an increase in wages of 10 per cent., to take effect Apr. 1, and that other working matters will be adjusted satisfactorily with the men. Several years ago this company put into effect an agreement whereby the employees share in the increased earnings of the company.

Tamaqua—The rest of the mine workers, about 3500 in number, employed by the Lehigh Coal & Navigation Co., in the Panther Creek Valley, who quit work recently because some of the men in the mines refused to join the union, returned to work Mar. 18.

West Virginia

Charleston—A trial of much interest to coal men has been going on in the United States Court at Cincinnati for the past four weeks; namely, the suit of the McKell Estate vs. the Chesapeake & Ohio Ry. Co. The McKells own 23,000 acres in the heart of the New River coal field, probably the most valuable tract of the size in West Virginia, and have sued the railway company for $3,700,000 damages, with interest, on a contract made by M. E. Ingalls when president of the Chesapeake & Ohio with the late Col. T. G. McKell. Many prominent operators and engineers of the state have testified in the case, as the questions involved concern almost every phase of the coal business. Governor Harmon, of Ohio, for the railway company, and Judge Holt, of Huntington, W. Va., for the McKells, are the leading counsel, and the case has been bitterly fought at every step. Some remarkable testimony has been given, which is of great interest to coal men.

Welch—Eighty-one men were killed, Mar. 26, by a gas explosion in the Jed Coal & Coke Co.'s mine, at Jed, W. Va., six miles from here. Only 11 men escaped alive, and one of these died within an hour after being brought to the surface. So far, 33 bodies have been located. The fans, although damaged, continued to operate, with the result that enough air was present to admit searching parties immediately. Less than half an hour after the explosion, relief measures were started. Oxygen helmets and other appliances were rushed from the plant of the United States Coal & Coke Co., nearby, and a government rescue car, *en route* to Huntington, W. Va., was turned back. The mine was inspected Mar. 22, and pronounced safe. Preliminary investigations so far have not divulged the cause of the explosion. Barometers in this vicinity have been showing unusually low readings for the last week without the usual atmospheric changes.

Canada

Merritt, B. C.—The British Columbia Development Co., capitalized at $800,000, has been organized by a group of Minnesota capitalists, including several Minneapolis men, and has acquired control of 1000 acres of coal lands in and about the town of Merritt, Nicola Valley, British Columbia. S. H. Hudson, Benson, Minn., is president; J. W. Irwin, Minneapolis, vice-president, and P. M. Endsley, Minneapolis, treasurer.

Personals

G. P. Bartholomew, who has been engaged in consulting work for the Pennsylvania Coal & Coke Corporation for the past seven months, has returned to his office, 30 Church St., New York.

J. C. Maben, president of the Sloss-Sheffield Steel & Iron Co., recently visited the company's properties in the vicinity of Birmingham, Ala., and elsewhere in the state, also looking over the plans for extensive improvements that are contemplated.

William L. Martin has resigned as superintendent of the Pratt No. 1 division of the Tennessee Coal, Iron & R.R. Co.'s coal mines, effective Apr. 1, to become superintendent of the Banner mine of the Pratt Consolidated Coal Co., succeeding Milton H. Fies.

John H. Parrott, general manager of the American Coal Co., recently visited Lonaconing, Md., for the purpose of inspecting the company's properties in that locality and with a view toward possibly resuming operations at the Jackson mine, as well as undertaking development of the Caladonia mines.

Maxwell L. Barker, of Louisville, Ky., formerly president of the Straight Creek Coal Co., of Pineville, has been elected president of the reorganized Nebo Consolidated Coal & Coke Co., in which he recently purchased a controlling interest. R. B. Winkler will remain as superintendent of the Nebo mine.

N. P. Turner has resigned as chief engineer of the Cuba R.R., and in association with L. D. Moore, of New York, will engage in consulting work, general engineering and exploration in the West Indies and the tropics. Mr. Turner will be located for the present at Hotel Camagüey, Camagüey, Cuba.

Milton H. Fies has resigned as superintendent of the Banner mine, of the Pratt Consolidated Coal Co., effective Apr. 1, and will engage in business for himself. Up until several months ago, Mr. Fies was engaged by the Birmingham Coal & Iron Co. as general superintendent, in charge of the Mulga and Short Creek mines.

W. F. Guiterman has been appointed vice-president and general manager of the New River Collieries Co., which is owned by the Guggenheim interests, and is one of the largest producers in the New River field, West Virginia. It is understood that Mr. Guiterman will make his headquarters in New York, and that a resident mine manager will be appointed.

William D. MacLean, general purchasing and sales agent for the Utah Fuel Co., has resigned to become general auditor for the W. G. Sharp coal properties at Mohrland, Hiawatha and Black Hawk. A. D. Pierson, for years assistant to Mr. Mac Lean, has been named general sales agent for the Utah Fuel Co., and H. N. How has been appointed general purchasing agent to succeed Mr. MacLean.

Obituary

John Maguire, one of the best known mining men in the anthracite region of Pennsylvania, died in the Pottsville Hospital, Mar. 11, following an operation. He had been an invalid for several years. Mr. Maguire was for many years mine inspector of the eighth anthracite district and later became division superintendent for the Philadelphia & Reading Coal & Iron Co., with supervision over all collieries south of the Broad Mountain. He was born in Whitehaven, Cumberland, England, in 1845 and at early age came to this country, serving in the Union Army during the Civil War as a member of the Seventh Pennsylvania Cavalry. Under his supervision, as district superintendent, the remarkable record of winning 95 per cent. of the coal bed was made at the Brookside colliery of the Reading company. Mr. Maguire served as mine inspector from 1894 until 1902. His conduct of the office was appreciated by operators and miners alike; he was a man of sound judgment and absolutely fearless in the performance of his duty. Mr. Maguire was known as one of the men in this field most thoroughly versed on anthracite mining and his advice was always eagerly sought.

Construction News

Flint, Mich.—It is reported that Saginaw mining interests will expend $160,000 in opening a mine within the Flint city limits. A shaft will be sunk and about one mile of railroad built to connect with the Grand Trunk R.R.

Bay City, Mich.—A shaft will be sunk and a mine opened on the Handy coal property, near the Whatcheer mine, south of Bay City. The proposed equipment calls for electric mining machines and haulage motors and a first-class installation throughout.

Canton, Ill.—The Big Creek Coal Co. is planning improvements for its Cuba mine in order to materially increase the output.

Superior, Wis.—The Great Lakes Coal & Dock Co., of Minneapolis, a subsidiary of the White Oak Coal Co., plans extensive improvements for its dock here, which it has recently leased from the Great Northern Ry. These improvements will include widening the dock 150 ft., and installing at least one new bridge, besides other equipment.

Earlington, Ky.—The Nebo Consolidated Coal & Coke Co. has been reorganized, with Maxwell L. Barker, of Louisville, as president, and extensive improvements will be made in order to greatly increase the output. Modern machinery will be installed.

Charleston, W. Va.—The Gauley Mountain Coal Co., Ansted, W. Va., will open up three mines on Rich Creek to develop 12,000 acres of No. 2 Gas seam, and will erect a large central power plant. J. J. Marshall is chief engineer.

Publications Received

REPORTS RELATING TO MINERALS AND MINING IN NEW ZEALAND, 1911. 160 pages, 8½x13 in., illustrated. John Mackay, government printer, Wellington, New Zealand.

The general report on coal mines takes up 40 pages. A specially interesting section of the book is that devoted to a separate report on the operation of the government-owned coal mines.

REPORT OF WEST VIRGINIA GEOLOGICAL SURVEY ON JACKSON, MASON AND PUTNAM COUNTIES. 387 pages, 6x9 in., 36 plates and illustrations and case of 3 maps. Price, $2. West Virginia Geologic Survey, Morgantown, W. Va.

In addition to the detailed study and description of all the rocks, minerals, soils, streams, and industries found within the area, the geologic map gives the structural contours on the Pittsburg coal horizon, as well as the approximate area underlaid by that bed. The topographic map shows by contours and figures the elevation of the surface, and its character, whether steep, rolling or level, and in addition gives all the streams, roads, railways, towns, churches, school houses, mines, houses, etc., in their correct locations.

INDUCTANCE OF COILS. By Morgan Brooks and H. M. Turner. Bulletin No. 53 of the Engineering Experiment Station, University of Illinois. 72 pages, 6x9 inches, illustrated. Free on request.

This bulletin discusses the theory and determination of the self-inductance of coreless coils. An empirical modification of the common formula for the inductance of solenoids, is presented as the Brooks universal formula applicable to all forms of cylindrical coils. Easy methods are given for predetermining the dimensions of a coil for any required reactance or inductance, for any purpose from the massive power protective coils to the smallest instrument coils. Definite coil proportions are assigned for producing the maximum inductive effect with a given length of conductor and data are furnished on the relation of the mutual inductance of adjacent coils to their self-inductance.

Industrial Notes

The Dominion Iron & Steel Co., Sidney, N. S., has placed an order with the Ruggles-Coles Engineering Co., 50 Church St., New York, for one of their Class A-14 dryers for drying 40 tons of coal per hour.

The new coal-handling plant for the Metropolitan Coal Co., at Chelsea, Mass., the plans and specifications for which are being prepared by Monks & Johnson, architects and engineers, 7 Water St., Boston, Mass., includes an extensive piled wharf, discharging berth, lighterage berth for coaling tow-boats, conveying machinery, cable road, 10,000- to 15,000-ton elevated pocket, 2000-ton ground storage shed, revolving pickup tower, storage facilities for 15,000 tons of bituminous coal in the open, screening plant for sizing anthracite screenings, boiler plant, stable, offices, etc. It is estimated that this new equipment will cost over $100,000.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The tense feeling in the coal market continues unchanged. Consumers and producers are both keenly watching the results of the wage conferences, many of the larger interests having special representatives on the ground to insure reliable and prompt reports on the situation. It is purely a strike market and has been accepted as such by the trade, which is now playing a waiting game.

The movement to the Eastern markets continues to be only sufficient to meet current demands, and none of the companies are accumulating any surpluses. Prices are at the same high level, although they vary considerably with the reports on the labor situation. Water freights are somewhat lower and the railroad congestion is rapidly improving. In the Pittsburg steam markets there is a disposition on the part of the consumers to shut down their plants rather than buy at the prevailing high prices.

The improvement in transportation in Ohio, due to the milder weather, has resulted in a heavy movement of delayed coal into the consuming centers. Emergency fuel, however, still commands a substantial premium, especially in the steam grades, and there is considerable buying for speculative, as well as storage purposes. The Kentucky trade experienced a decided flurry on some heavy orders from St. Louis, but the market there soon broke and the Kentucky operators are now waiting for the strike to materialize.

The demand in the Middle West is unprecedented with the exception of St. Louis, where the market was overshipped, and now has coal on demurrage. There is no free coal to be had at other points, and the large consumers are becoming worried and bidding up prices on all grades. There is a decided stiffening in all departments and the producing companies are mostly sold well ahead.

Boston, Mass.

The week has shown a fluctuating market, according as the news tended to back up the strike talk or show possibilities of a compromise. Mild weather was followed by a northeast snow storm and prices hardened measurably. This market, even for the near inland points, is now practically confined to all-rail delivery for bituminous and a heavy tonnage is moving over the lines with Eastern connections.

Most of the regular shippers and a number of new ones have coal going to the junction points for reconsignment. Prices are being held at a high range for such coal in transit and were it not for fluctuations during warm weather and rumors of settlement early in the week they would be higher still. As it is, the average is about the same all-rail as a week ago, although at tidewater distributing points, such as Boston, Providence and Portland, new high prices are reported.

In anthracite the companies are rapidly going out of business, at least so far as concerns Eastern shipments. Consignments from New York have practically ceased on all sizes and Philadelphia has been so seriously curtailed that only a very few special kinds and sizes are to be had, and those only in small quantities.

On anthracite all-rail, and at New York, on individual coal, premiums run all the way from \$1@2, although the offerings seem small.

The following list gives some idea of current prices at wholesale:

Clearfield, or any bituminous, f.o.b. Philadelphia	\$3.60@4.10
Clearfield, f.o.b. New York	3.50@4.35
Clearfield, *en route*, f.o.b. mine basis	2.25@3.50
Pocahontas, New River, f.o.b. Hampton Roads	4.75@5.25
Thacker and Kenova, f.o.b. Hampton Roads	3.50@4.00
Pocahontas, New River, Boston, on cars	6.00@6.75
Pocahontas, New River Providence, on cars	5.75@6.75
Anthracite, stove, etc., all-rail, f.o.b. mines	4.50@5.50
Anthracite, domestic sizes, f.o.b. New York	6.00@6.75

New York

It is believed the New York trade is facing the possible suspension at the mines with very meager supplies. The demand here has been urgent in the extreme, and in many instances shippers have been obliged to go into the open market for tonnages to meet their contracts. No accumulations are being made at the piers and with the strike now practically at hand no hopes are entertained for getting any.

Prices continue to rule high, and there is no perceptible evidence of the situation easing off in either anthracite or bituminous. The lowest grades of bituminous are quoted at \$3.50@3.75, f.o.b. piers, which would be equivalent to about \$2 at the mines. A further complication, to a situation already bad enough, is now threatened by a labor shortage at the mines shipping to the New York markets. The movement on the railroads has improved considerably, but is by no means back to normal.

We continue to quote wholesale anthracite prices, f.o.b. New York, as follows:

Broken	\$5.50@6.00
Egg	5.50@6.00
Stove	6.50
Chestnut	6.50
Pea	5.00@5.25
Buckwheat No. 1	4.00@4.50

Philadelphia, Penn.

The past week has been one scramble for coal. Householders realize that every indication points to trouble at the mines on Apr. 1, and dealers have been besieged on all sides to fill orders. This is not only true of the residential districts, but the mill districts as well. Quite a number of the manufacturing plants in this city use the smaller sizes of anthracite, and none of them have any great stocks on hand. As the supply from the mines has been inadequate to fill more than current business, many of them will go into April very poorly fortified against a lengthy struggle between the miners and operators.

Pea coal is bringing from \$3@3.50 at the mines, buckwheat from \$2@2.50, and of the size called rice, there does not seem to be any at any price. As a matter of fact, most all the operators have contracts on which they are applying their entire output, and little free coal is on the market. The domestic sizes are also in excellent demand, and dealers are taking anything that is offered.

The individual operators are reaping a harvest, as the so called circular prices are entirely ignored, and most every car of coal sold now brings a good premium. For spot coal, anywhere from 50c. to \$1 above the circular is being paid. The large operators in no case, it is understood, have advanced the price over the ruling circular, for which they are receiving little credit from the press in this vicinity. Any advance in the price of any size is ascribed to the coal trust, who are also unjustly accused of holding coal back at the mines. It is possible some of them are laying aside some of the output for their own use at the mines, but outside of this, the entire production is coming to market. The first of April will see a comparatively small tonnage of anthracite coal on hand.

Pittsburg

Bituminous—The meeting at Cleveland has afforded no good reason to change the original expectation that there will be a suspension of several weeks—these reports having guessed six weeks as the most probable duration—with proposals and counter proposals in order to keep up interest and show that the respective parties were making efforts toward a settlement.

The bituminous-coal market continues in a very unsettled state, but is not as excited as it was, as consumers and producers have now accepted the scarcity, which will merely be accentuated gradually after Apr. 1 when the mines presumably will close. Several weeks ago prices reached such a point that regular large consumers, who had made some provision against the impending suspension, refused to pay them and the buying in the open market has been merely of odd lots. In many cases the requirements of consumers are of such a nature that they will cease operations rather than pay fancy prices.

The bottom of the market may be placed at the same level as in the last report, but transactions are more limited, and especially high prices are more frequently paid for odd prompt lots. We therefore quote as the minimum of the market, and coal hard to buy at the prices: Mine-run and nut, $1.50@1.60; ¾-in., $1.65@1.75; 1¼-in., $1.90@2; slack, $1.40@1.50, per net ton at mines, Pittsburg district.

The Elkins Coal & Coke Co. is reported to have closed a 20-year contract with the Lehigh Coke Co., South Bethlehem, Penn., for 1200 to 1500 tons of coal daily, for the byproduct coking plant just being completed. This plant was built by German interests, to supply coke to the Bethlehem Steel Co. for 20 years, with an option reserved to the Bethlehem company to buy the plant at the expiration of the period. The coal is to be mined from the new Bretz field.

Pittsburg-district operators are somewhat more anxious to close the wage negotiations than they were before the Interstate Commerce Commission decision reducing the lake rate from 88 to 78c. While the operators asked for a reduction to 50c., they were not certain of securing any, so that the 10c. saving is of interest and will make the district more keen in securing lake tonnage.

Connellsville Coke—The market is not closely quotable, as demand has decreased and the supply also. Consumers are trying to get along with the coke available, and are chary of buying additional tonnages at the fancy prices asked. We quote the market roughly at $2.25 for furnace and $3 for foundry coke, per net ton at ovens.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Mar. 16 at 408,237 tons, an increase of 10,000 tons, and shipments at 4525 cars to Pittsburg, 6271 cars to points West and 1189 cars to points East, a total of 11,985 cars, or a decrease of 149.

Baltimore, Md.

Although a few of the operators reported a tendency to ease up somewhat in the Baltimore market, the latter part of the week found the demand for coal just as strong and prices just as firm. The majority of the large operators in this city state that they are unable to supply consumers with sufficient fuel, owing to the inability of the operators to furnish the coal. It may not be generally known but there is a scarcity of labor in many of the coal fields of West Virginia at the present time. One operator who returned to Baltimore a few days ago made the remark that between 2000 and 3000 additional men could be utilized in the mining districts if they were to be had.

Lack of labor has, in many instances, handicapped the operators in their efforts to fill orders at the prevailing high prices. Prices have gradually advanced since about the time the strike started in England. This was nearly three weeks ago, and since that time almost phenomenal prices have been asked and received by the trade.

Buffalo, N. Y.

The market began to slack off several days ago and at present there are a few jobbers with coal on track that they are finding very little market for. The better weather has released a lot of coal that was held up at various points and the New England demand dropped off a week ago, on account of supplies from other fields, probably West Virginia chiefly. Besides the consumer now finds the rush prices too high for him to buy more than he is obliged to.

It is still impossible to quote actual bituminous prices. Nominally they are $2.60 for Pittsburg three-quarter, $2.50 for mine-run, $2.25 for slack, and $4.25 for the best Connellsville foundry coke, but the actual price, paid in emergency, runs all the way to $1 higher. Coke is also from 25 to 50c. above former prices, if the consumer is short. It may not go down again when the labor troubles are over, as consumption is improving and it has been very low for a long time.

The anthracite situation is unchanged, the demand being strong enough to take everything the mines can turn out. Lake shippers are very uneasy over the outlook as with many vessels loaded for early shipment, there is none to load now, while the upper-lake docks are bare, as a rule. All sizes are almost uniformly scarce, which is also a very unusual condition of things at this time.

Columbus, Ohio

The feature of the Ohio market during the past week was the strong demand for all steam sizes as a result of which prices have ruled higher than for months past. Steam users have been brought to realize that the possibilities of a suspension after Apr. 1 are great and every effort has been made to stock up. But railroad traffic has been so demoralized and the car shortage so pronounced that the efforts to collect a supply of fuel were not productive of great results.

As a result of the movement to cover, practically all of the railroads in Ohio have supplies to last from 30 to 60 days and some of the larger manufacturing establishments are also well supplied. But others are not fortified for a long suspension and much inconvenience is expected if the strike is prolonged for any great period. West Virginia is beginning to ship coal westward now, attracted by the high prices prevailing in that market.

The condition in railroad transportation is not much improved. Congestion still prevails at Toledo and other connecting points and empties are slow in finding their way back to the mines. As a result operations have been restricted to about 65 per cent. of normal during the past week.

Prices prevailing in Ohio are as follows:

Hocking Valley	
Domestic lump	$1.65
¾-in.	1.80
Mine-run	1.60
Nut	1.75
Nut, pea and slack	1.65
Coarse slack	1.55
Pittsburg No. 8	
¾-in	$1.70
Mine-run	1.70
Coarse slack	1.70
Pomeroy Bend	
Domestic lump	$1.75
¾-in	1.60
Nut	1.50
Mine-run	1.50
Nut, pea and slack	1.50
Coarse slack	1.40
Kanawha	
Domestic lump	$1.45
¾-in	1.60
Mine-run	1.60
Slack	1.50

Cleveland, Ohio

Conditions in this market are such that it is a difficult matter to give any accurate information as to which way the market will go. Operators and miners, at their meetings held in this city, have not arrived at any definite results, and the market at the present time is in such a condition that it is impossible to determine what will happen between now and Apr. 1.

There has been considerable coal shipped to this market in the past week by parties, who are holding it on track with the expectancy of obtaining higher

prices. They will, no doubt, realize their expectations, as whether or not the operators and miners get together, there certainly will be a suspension for at least 30 days, and the prices on all grades will in consequence increase very materially.

The larger manufacturers in this vicinity have stocked up sufficiently to keep them running for at least 30 days or more. The smaller concerns not having facilities to handle the coal, will have to pay the increased prices should the strike materialize.

Charleston, W. Va.

The conditions that prevailed in this state a week ago have not been materially changed—the car supply has not improved, although there is just as great a demand for coal and prices are getting stronger. Shipments East are handled without trouble and instances have been cited where the same car has been loaded at the same mine twice within the same week, but shipments to the West have not been so satisfactory. The question of motive power which for a while interfered greatly with the handling of cars has been relieved.

Opinions among operators differ as to whether many men will go out on Apr. 1. Some believe there will be a considerable number while others only look for a strike in several places where the miners' organization has any material strength.

Predictions are freely made that if the anthracite miners go out, bituminous coal will reach $5 a ton by Apr. 10, or practically three times the prices prevailing at this time.

Louisville, Ky.

The outcome of the controversy between the operators of Pennsylvania, Ohio, Indiana and Illinois, on the one hand, and the miners on the other, over wage scales, is being watched with keen interest by the operators in Kentucky. The miners of the western Kentucky fields are affiliated with the United Mine Workers of America, with headquarters in Indianapolis. The Kentucky miners, however, are left to their own resources unless they appeal to the union, or are called upon by the latter to strike. As a result, the operators in Kentucky will not be certain just where they stand until the contest between the miners and operators in the tri-state agreement is decided.

Louisville has a supply of soft coal, including Pittsburg, sufficient to last six months, but if this is drawn upon by other cities as a result of the general shortage, the local supply would be converted into a shortage in a comparatively short space of time. Representatives of coal companies from Chicago and other points have been here recently seeking to purchase coal in the event of a general suspension of work among both the hard- and the soft-coal fields. If this shortage materializes it will mean materially higher prices locally, especially if the stringency lasts very long.

Nashville, Tenn.

Up until Mar. 15, the west Kentucky coal fields were making heavy shipments, both into St. Louis and Chicago, the markets there being very bullish up to that time, but on Mar. 16 the bottom dropped out of the market in St. Louis. At the present time the Louisville & Nashville R.R. has something like 400 cars of coal on demurrage at that point and an embargo has been placed on many prominent firms shipping into St. Louis.

The demand for screenings is still very great, although the market is dead at the present on the other sizes. Everyone is waiting on the conference at Cleveland, and a number of large buyers have discounted the results ahead of time and prepared for a disagreement. Should a general suspension occur in the bituminous field, the nonunion mines on the L. & N. and the I. C. in west Kentucky will reap one of the richest harvests they have ever known and operators in this section are hoping that such will be the case.

Indianapolis

Indications show an impending crisis in the coal situation in this state. The unexpected cold weather occasioned a coal famine in a number of towns and cities. The wholesale dealers refuse to quote prices and retailers, in the market for coal, either do without or pay the high price asked by the operators.

It does not make much difference as to quality. The question of quality is becoming secondary as all coal looks alike to the would-be purchaser who needs it. The railroads continue to store in great quantities, the only exception being the Southeastern, the old Walsh Southern Indiana. It has made an agreement by which the operators have been favored by getting as much coal to the market as possible, in preference to filling orders for storage purposes. In return the operators in the Linton or Green County field have agreed to give the railroads the entire output of 30 mines the last day before the suspension, which will amount to nearly 300 cars.

Minneapolis—St. Paul

Wholesale men here spend most of their time turning down orders or discussing the strike situation. Very little fuel is to be had as practically all coal is sold at the docks and most Illinois mines are reported to be sold up to Apr. 1. Of the coal coming into Minneapolis from Illinois fields, it is reported that only one or two cars now *en route* are not sold.

Steam users in and around the Twin Cities are beginning to be worried as the strike time approaches and have been asking for quotations quite freely on any kind of coal regardless of grades or sizes. They are beginning to realize now that they have taken too optimistic a view of the situation and some of them are clamoring right and left for supplies. The bituminous supply at the head of the lakes is almost exhausted and dock men are not taking any new orders but are holding what they have to supply their regular customers.

A canvas of the retail yards here showed that very little anthracite was in stock. Only small 30- or 40-ton lots were found here and there of nut, stove and egg sizes. No dealers report having any cargo pea or buckwheat. One large retailer had enough foresight to order several cars of anthracite all-rail which he says is coming along nicely and will be here shortly. With the docks swept clean of hard coal and no prospects now of having orders filled, all-rail from the East, it is the general belief that prices will not decline on anthracite as is customary Apr. 1.

Chicago

There has been a stiffening all along the line in the Chicago coal market. Steam lump and mine-run range from $2@2.22 f.o.b. the mines, screenings at from $2.10@2.32 and the same for domestic lump.

Producing companies which supply the most of the Chicago market have sold out their available supply for the remainder of this month. About the only coal in this market commanding attention is smokeless mine-run; this is now selling f.o.b. Chicago at $4.25@4.50, which is on the basis of $2.20@2.45 f.o.b. the mines. Most all of the Carterville operators are sold up, but some few companies have a little coal remaining.

Prevailing prices at Chicago are:

Sullivan County:	
Domestic lump	$3.00
Egg	3.00
Steam lump	3.00
Screenings	$3.00@3.10
Springfield:	
Domestic lump	$3.00
Steam lump	3.00
Mine-run	3.00
Screenings	3.00
Clinton:	
Domestic lump	$3.00
Steam lump	3.00
Mine-run	3.00
Screenings	$3.00@3.10
Pocahontas and New River:	
Mine-run	$4.25@4.50
Lump and egg	4.25@4.50

Prices asked for coke are: Connellsville and Wise County, $4.85; byproduct, egg and stove, $4.95; byproduct, nut, $4.75; gas house, $4.90@5.

St. Louis, Mo.

As prophesied in last week's report, the break in the market that has been expected for the past two or three weeks came the latter part of the past week. Everything in the way of local coals took a slump, and the beginning of the present week finds the market in a demoralized condition. Railroad orders are about cleaned up, and this has thrown considerable free coal on the market, for which there is no demand.

The chances are from now on, unless something unexpected turns up, the market will continue weak. One of the causes of the St. Louis market breaking was the buying of between 800 and 900 cars of Kentucky coal by St. Louis jobbers, who were anticipating a rise in the market. The close of last week found close to 500 cars of Kentucky coal under demurrage at East St. Louis, and several hundred more in transit. It was simply impossible to move this coal at any figure, and everything indicates that a portion of it will remain on track for a week possibly before it is cleaned up. Buyers who had not stocked, bought Kentucky coal at their own figures, and this demoralized the Illinois market.

The market opened the early part of the week about as follows:

Franklin County	
Lump and egg	$1.90@2.00
No. 1 nut	1.90@2.00
No. 2 nut	1.75@1.87
No. 3 nut	1.75@1.80
2-in. screenings	1.60@1.70
Carterville	
Lump and egg	$1.85@2.00
No. 1 nut	1.85@1.95
No. 2 nut	1.75@1.85
No. 3 nut	1.70@1.75
Screenings	1.60@1.70
Mine-run	1.55@1.65
No. 1 washed	2.00@2.10
No. 2 washed	1.90@2.00
No. 3 washed	1.85@1.95
No. 4 washed	1.75@1.85
No. 5 washed	1.60@1.70
Standard	
6-in. lump	$1.70@1.80
2-in. lump	1.60@1.70
Screenings	1.55@1.65
Mt. Olive	
6-in. lump	$1.85
3-in. lump	1.75

San Francisco, Calif.

In the past week heavy rain has fallen throughout California; this, coupled with a cold, chilly wind, has materially increased the consumption of coal. A continuance of these conditions should reduce stocks considerably, affording the dealers an opportunity to get their yards in good shape prior to the slack summer months' trade.

Current prices to the trade are as follows, per long ton:

Wellington, B. C.	$8.00
Pelane Main (Australia)	8.00
American canal	8.15
Rock Springs	9.00
Cumberland	12.50
Peacock (Rock Springs)	7.90

Portland, Ore.

The British ship "Kircudbrightshire" arrived in the Columbia River this week with a cargo of coal from Australia. This will be the last cargo to come here this season from Australia, and coal dealers are glad of it because the overhold stock is quite sufficient as it is.

The market here is inactive and from now on till fall the demand is not expected to come from the regular sources. Oregon and Washington are enjoying ideal spring weather but snow fell in some parts of Idaho during the week. It is expected that storage prices will be announced early this year, owing to the large carry-over stock.

Production and Transportation Statistics

Norfolk & Western Ry.

The following is a comparative statement of coal and coke shipments over the lines of the N. & W. Ry. for the first two months of the years 1911-12, in short tons:

Destination	1912	1911
Coal		
Tidewater, foreign	219,893	175,851
Tidewater, coastwise	535,943	398,518
Domestic	2,716,413	2,219,078
Coke		
Tidewater, foreign	8,544	20,466
Domestic	261,020	294,103
TOTALS	3,741,813	3,108,021

Chesapeake & Ohio Ry.

The following is a statement of coal and coke traffic over the lines of the C. & O. Ry. for January and 7 months ending January, 1912, in short tons:

C. & O. Ry. Shipments

Destination	January	7 Months
COAL		
Tidewater	335,290	2,305,754
East	212,314	1,281,733
West	750,103	6,485,874
Total	1,297,707	10,073,361
Bituminous from connections	18,914	136,240
Anthracite from connections	3,155	21,904
Grand total	1,319,776	10,231,505
COKE		
Tidewater	58	1,338
East	8,540	66,494
West	7,605	50,228
Total	16,203	118,060
From connections	1,237	9,997
Grand total	17,440	128,037

The Car Situation

Statement of idle cars as reported to the American Railway Association as of Mar. 13, shows that the peculiar conditions which have been reflected in recent weeks still prevail. The net surplus on the last date reported was but 3033. Two weeks ago the surplus was 7842. The gross surplus of idle cars is 46,028, but shortages totaling 42,985 made the net surplus the smallest in years. This condition resulted from an unequal distribution of the empty cars. In the two weeks ended Mar. 13 the surplus of coal cars decreased from 10,239 to 9844, and the box-car surplus increased from 9024 to 12,910. Shortages in these classes of cars, however, increased decidedly.

Foreign Markets

Prussia

The total production of coal in Prussia for the year 1911 was 13,721,845 tons, as compared with 12,731,097 for 1910. Production of other fuels in 1911 was: Lignite, 5,609,731 tons; coke, 2,326,966; coal briquettes, 419,028; lignite briquettes, 1,265,335. The total production of these latter in 1910 was: Lignite, 5,195,384; coke, 2,219,226; coal briquettes, 401,514; lignite briquettes, 1,170,529 tons.

German Empire

Fuel production in the German Empire for 1911 was: Coal, 14,565,606; lignite, 6,865,208; coke, 2,340,366; coal briquettes, 424,961; lignite briquettes, 1,497,060. The production of these same fuels in 1910 was: Coal, 13,527,215; lignite, 6,319,544; coke, 2,231,865; coal briquettes, 405,625; lignite briquettes, 1,383,503.

Financial Notes

Westmoreland Coal Co. declared the semi-annual dividend of 3 per cent. and an extra dividend of ½ of 1 per cent., payable Apr. 1 to stock of record Mar. 19.

The American Coal Products Co. has declared the regular quarterly dividend of 1¾ per cent. on its common and preferred stocks. The former is payable Apr. 1 to holders of record Mar. 25, and the latter on Apr. 15 to holders of record Apr. 10.

Notwithstanding the fact that the New England Coal & Coke Co. delivered 14 per cent. more coal in January of this year than in January, 1911, and 4 per cent. more in February this year than in the same month in 1911, the net profits for the two months are substantially less.

Annual report of the Consolidation Coal Co. for the year ended Dec. 31, 1911, shows gross earnings of $11,420,694, as compared with $12,712,256 for the year 1910. Net earnings after deducting depreciation were $2,652,414, as compared with $3,215,226 for the year 1910. Dividends for the year 1911 were $1,201,513, and the balance surplus was $182,322, as compared with $1,141,522 and $571,024, respectively, for the year 1910.

A syndicate composed of the National City Bank, Lee, Higginson & Co. and Kissel, Kinnicut & Co., has bought from the Tidewater Co., which controls the Virginian Ry. in the interest of the H. H. Rogers estate, $25,000,000 of first mortgage 5 per cent. 50-year gold bonds of the Virginian company. The principal purpose of the sale is the payment of $17,000,000 of Tidewater Co. 6 per cent. notes which have been called for redemption on June 1. Another $1,000,000 of the proceeds will be used for improvements.

Alphabetical Index to Advertisers

Classified Index to Articles Advertised

POSITIONS VACANT

Advertisements under this heading 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Wanted—A graduate mining engineer to take charge as general superintendent of a coal operation producing about 1,000,000 tons per annum; must be an organizer and possessed of unusual executive ability; salary about six thousand dollars per annum. Address "Miner," Coal Age. Apr. 13.

SITUATIONS WANTED

Advertisements under this head 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Position as master mechanic by a young man of electrical and mechanical experience; able to handle anything of either line around a modern equipped mine; Sullivan cutting equipment preferred; open for engagement after April 1. Address Box 17, Coal Age. Mar. 30.

Wanted—Position as mine foreman; prefer a large mine; 20 years' experience as pit boss, also in electric haulage and machine mining; can furnish first-class references as to temperate habits and ability to handle men; hold a first-class certificate of West Virginia; open at present. Address Box 21, Coal Age. Mar. 30.

Wanted—Change of position by experienced superintendent; have engineering experience; have worked colored and foreign labor, rope and electric haulages, air and electric machines; good record for tonnage and economy; 10 years' experience in charge of mines for some of the largest coal companies in United States. Address Box 18, Coal Age. Apr. 13.

State of New York } ss:
Office of the Secretary of State }

THIS CERTIFICATE issued in duplicate, hereby certifies that THE ENGINEERING NEWS PUBLISHING COMPANY, a domestic stock corporation, has filed in this office on this 20th day of March 1912, papers for the voluntary dissolution of such corporation under section 221 of the General Corporation Law, and that it appears therefrom that such corporation has complied with said section in order to be dissolved.

WITNESS my hand and the seal of office of the Secretary of State, at the City of Albany, this twentieth day of March, one thousand nine hundred and twelve.

(Signed) Jose E. Pidgeon, Second Deputy, Secretary of State

Moments with the Advertising Editor

There was some "good stuff" in an article on "Honesty in Advertising," in the New York "Globe" the other evening. It was written by Bert M. Moses, President of the Association of American Advertisers, and was so interesting that we are going to reprint it here:

"So far as can be learned from History, the wail of the world has ever been for honest men.

"With honest men in control, every problem that has confronted civilization from the Beginning to the Now would be solved.

"There would be no poverty, no crime, no wars, no epidemics, no race or religious hatreds, no discordant note anywhere.

"No one has ever undertaken to count the laws that have been passed to make honesty compulsory.

"These statistics, however, are available: In the year 1910 alone there were passed by the Federal and State Legislatures over 44,000 new laws.

"A law is something whose purpose is to compel people to do or not to do certain things.

"A law, if just, aims to make men do that which they would do without law if they were honest.

"So it seems that a great majority of the enactments passed have as their object the promotion of honesty.

"What has been the result of all these hundreds of thousands of laws?

"Is honesty any more of a glut on the market than it ever was?

"The trouble has been this:

"The law never changed human nature. It never made anybody permanently honest.

"Mankind cannot be legislated into goodness. Morality does not find its source in a Legislature, but must leap straight from the heart.

"Just now there is a nation-wide movement to make advertising honest.

"Every decent man in America is supporting that movement, and all over the land advertising clubs and associations are lifting up their voices in favor of it.

"Perhaps a majority believes the remedy lies in the law.

"Others feel that there is a better way, and an only way, that ever banished any evil. That way is the Power of Public Opinion.

"Ten years ago dishonest, deceiving and false advertising was at its zenith.

"Exaggeration, falsehood, and plain lying were universal.

"The fakir and swindler were not the only offenders, but practically every advertiser indulged in extravagant and unwarranted forms of speech in promoting his wares.

"Then the real work of reform started.

"Publishers began to refuse that particular form of advertising which was fraudulent on its face.

"More and more closely was the copy scanned as time passed, until to day the professional swindler finds his way so almost completely barred that his vocation of collecting coin by fraudulent advertising is about gone.

"There still remains that semi-respectable form of advertising that deals largely in superlatives and exaggeration. But progress upward has been rapid, and it has come about, not because of law, but because men are learning without enactment that honesty is a paying proposition.

"They are learning that truthful advertising, which the public believes, 'pulls' better than misleading advertising that the public suspects.

"Public opinion is a power above and beyond laws, and, so far as I can learn, no law ever made public opinion.

"Laws are for lawyers.

"Once get advertising into their hands, and the issue will be so clouded that no man will know what he may or may not say in public print.

"Truth is a point of view, and in all History no man has yet appeared who was wise enough to say, 'This is surely so, or that is surely not so,' in the matter of merchandise.

"Public Opinion is at work, and its influence is widening and broadening daily.

"To now rush in and try to accomplish by law that which is being accomplished without law would be a blunder.

"That is the way the thing looks to me."

Doesn't this help to show why it pays to read the advertisements in your paper, and to buy advertised goods?

COAL AGE

Vol. 1 NEW YORK, APRIL 6, 1912 No. 26

HALTING conservatism is the keynote of our mining methods. We have been afraid to blaze a brand new trail, and we tinker along, modifying old contrivances. No other nation adheres so dutifully in mining to antiquated principles and first ideas.

Make no question, the man who will succeed will think a new thought, or, at the very least, will *take up* with a new one. There are minds aplenty which follow, but few that lead. The masses who march in the ranks have already worked out all the possibilities of initial methods.

How ineffectual is all our mining machinery, how ineffective our shooting, how difficult the introduction of loading machines, face conveyors and pneumatic tubes with such disjointed room-and-pillar systems as we persistently follow. Waste of coal, waste of labor, poor product, low output, all are the net results of present-day conservatism.

At any colliery where coke is made, a small proportion of the overs could be harnessed to a boiler plant. One oven will supply an average of 20 h.p. every day in the week. Not only will the operator find the first cost of the installation about the same, but he will discover that the coke is brighter, denser and heavier from the process.

The recovery of tar and ammonium sulphate by the use of byproduct ovens, and the utilization of waste gas, would pay interest on the total installation charges, and in addition, would cover the cost of coal, leaving the coke as velvet.

The gas producer at first seemed but the vain dream of enthusiasts, and many persons believed it could never be set at work on dollar coal or ten-cent slack. But European colliery managers proved beyond doubt the practicability and success of the system.

It's a fact therefore today, that many of us advocate the installation of producers so as to make it possible to use fuel which can't be employed under a boiler, or to burn a better grade with increased economy. One ton of coal will turn more wheels operating through a producer and gas engine than 2½ times as much of the same fuel with a boiler and steam reciprocator of normal type.

One ton of low-grade lignite from the Dakotas will give better results by the all-gas route than a ton of the best West Virginia product used in the stereotyped fashion. No coal is too poor for producer gas, and fuel containing 70 per cent. ash has been utilized. In England, carbonaceous shales and belt pickings are added to increase the heat value and to augment the sulphate output.

Our action with regard to turbines has been the same. We needed greater power, so we put in more reciprocators and had to install additional boilers and employ more men to maneuver the shovel. If we had acted in accord with advanced ideas, we could have obtained all the power needed, by using a low-pressure turbine to take care of the exhaust steam.

Many of the new steam-electric plants are reciprocator-driven, direct-current installations, ignoring the fact that reciprocators are less efficient and that the transmission of direct current is expensive.

A new era approaches. It is unreasonable that coal companies should be compelled to waste all the gas generated, because of hobbling charters which permit them only to market coal and coke. Collieries will not always ship their output to market, but will deliver gas or electric current, and we may yet see a large yield of ammonium sulphate made possible by the use of offal and the waste of sludge tanks and cesspools.

Even now, a ton of bituminous coal in a producer will give 85 lb. of sulphate, worth, say $2.64. One hundred-weight of sulphate is used to fertilize an acre. It is evident therefore, that a good sale can be obtained for the product. The tar can be used for briquetting; so that, over and above the 140 to 160 thousand cu.ft. of gas, a considerable profit remains.

The coal industry has only just begun. Before the century is over we may extract gas from the fuel deposits without mining, or we may consume the coal as an electrical anode in a giant battery cell.

Extensive Use of Coke-Oven Gas

By C. A. Tupper*

The use of coke-oven gas in combustion engines for the generation of power has rapidly developed until now a great number of large plants of this kind are in successful operation. These are found chiefly in Germany. There are many opportunities in this country for taking advantage of German experience and converting the waste gases of coke ovens into electric power and other valuable products.

In a recent issue of COAL AGE, I mentioned some of the possibilities of generating electric power from coke-oven gas, and described a plant typical of a number that I inspected during a tour of the coal-mining and coking districts of Europe. The plant referred to was that of the Gewerkschaft Minister Aachenbach, at Brambauer, Germany, which was equipped by Haniel & Lueg, of Düsseldorf.

The accompanying illustrations, however, will serve to give a much better idea of the extent to which such gas power is being utilized abroad. Fig. 5 shows the interior of the electric generating station, at Alsdorf, Germany, of the Eschweiler Bergwerks Verein, current from which is distributed to motors and used for lighting at all of that company's operations. This is the largest power station in the world, operated on coke-oven gas. It is equipped with engines built by the Maschinenfabrik Augsburg-Nürnberg, direct-coupled to alternating-current generators from the shops of the Allgemeine Elektricitäts Gesellschaft, at Berlin. There are nine of these units at present installed, with an aggregate rated capacity of 15,000 hp., and provision is being made for others. The gas used here is supplied from several batteries of Koppers regenerative coke ovens, partially illustrated in Fig. 4 in connection with which there is operated a byproduct plant for the recovery of ammonium sulphate, tar compounds, etc.

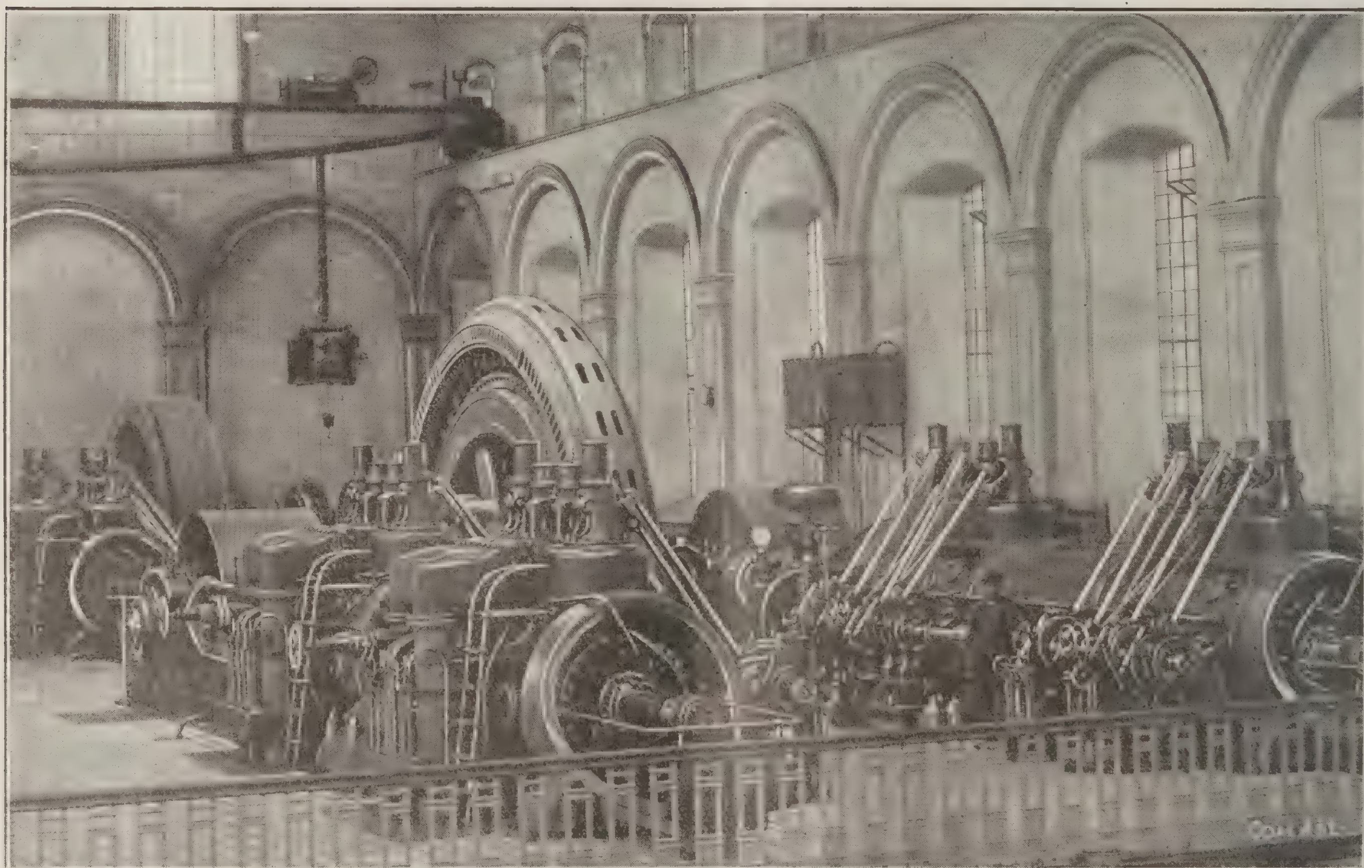

FIG. 1. GAS-POWER PLANT AT BARGOED, WALES

Originally, the gas from the coke ovens in use here, was burned under boilers, and the steam thus produced was consumed in a number of isolated engine plants installed, wherever necessary, over the wide area of the company's operations. For these comparatively small power stations, the total running expense and cost of upkeep were relatively high, particularly as it was necessary to carry a spare engine in each locality. The losses through condensation in some of the steam feeder pipes, which were, in places, of considerable length, also increased operating costs.

Gas-engine Driven Electric Plant

The obvious remedy for such conditions lay in the construction of a central electric-generating station and the complete electrification of all the company's plants. When it came, however, to deciding upon the type of prime mover to be installed, the verdict was in favor of gas engines, rather than the continued use of steam, for the reason that, with a steam plant of even the most efficient type ordinarily used, it is possible to convert into power only a much smaller percentage of the calorific value of the gas than can be utilized with gas engines. The management therefore decided to dispose of the steam engines, one after another, and gradually concentrate the production of power in a gas-engine-driven electric plant.

The gas being used under the boilers at that time would not, however, do for use in gas engines; and the next problem was to secure a product sufficiently free from impurities to serve this latter pur-

*Consulting engineer, 389 Thirty-first Ave., Milwaukee, Wis.

pose. The installation of a byproduct recovery plant was determined upon at the same time, and this provided for the removal of tar compounds, as well as some other deleterious substances; but the necessity remained for extracting the large percentage of sulphur present, and to provide for the effective removal of this, a special cleaning plant was constructed, which, like the one illustrated in the Nov. 25 issue of COAL AGE, consists primarily of layers of bog iron laid out on rough wooden lattice-work shelves. However, in this installation, fans are used for forcing the gas through the filter frames, and the tar extractors, originally used, have been eliminated. After the Koppers-type ovens had been substituted for an older type, these extractors were found unnecessary, as the byproduct plant effectually removed all tar. A central chamber also has been provided, where, as the ore becomes saturated, it can be dumped from the frames and regenerated by exposure to the air. The two sides of the filter are operated alternately, so as to afford opportunity for this freshening process, and thus the same ore can be used for a considerable length of time.

FIG. 2. KOPPERS BYPRODUCT PLANT, AT OESPEL

The gas, as cleaned, has a composition approximately as follows:

		Per cent.
Carbon dioxide	CO_2	2.00
Oxygen	O_2	0.82
Carbon monoxide	CO	5.82
Methane	CH_4	20.83
Other hydrocarbons	CnHm	1.40
Hydrogen	H_2	55.11
Nitrogen	N_2	14.02
		100.00

From the filter plant, the gas can be sent directly to the gas engines or to one of two gas holders, having a combined capacity of 52,500 cu.ft., from each of which two separate lines, with drain-off valves, etc., lead to the power station. Ordinarily the gas passes through these holders. To insure a sufficient supply of gas when the number of ovens in service is not equal to the demand, gas producers have been installed as auxiliaries. The present output of power represents about twice the amount, proportionately, that was formerly obtainable from the same number of ovens when steam engines were used.

COMBINED GAS-ENGINE AND STEAM-TURBINE SYSTEM

Without going further into the details of this station, which can be considered collectively with those of other plants, let us turn to the gas-power plant of the Royal Prussian Mines for the Saarbrücken district, at Heinitz, Germany. This contains seven engines, totaling 10,000 hp., and two more, which are to be put in operation before long, will increase the total to 16,000 hp. All the gas here used is supplied from Koppers ovens, similar to those shown in Fig. 4. This first passes through a byproduct plant and gas holders of 210,000 cu.ft. capacity. There are no producers held in reserve, but a steam-turbine plant at the other end of the district is connected with this station by transmission lines and operated in parallel with it, supplying whatever excess power is needed.

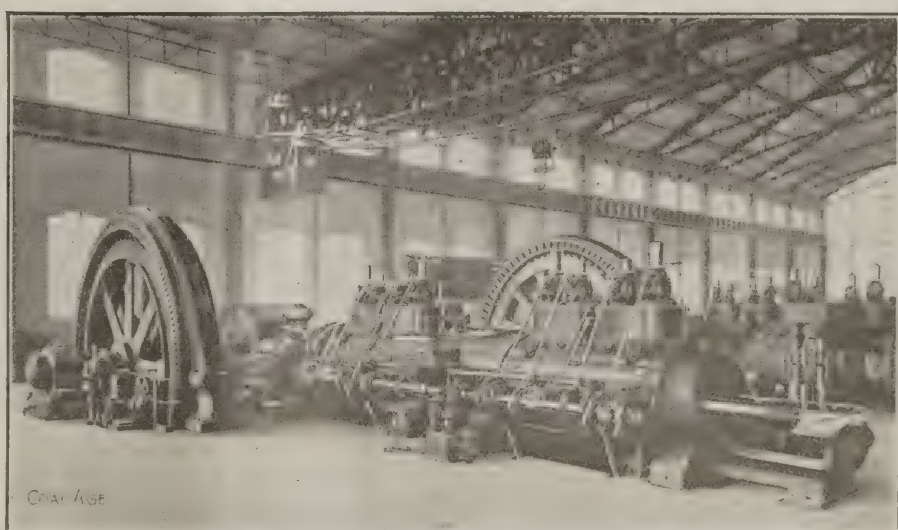

FIG. 3. GAS-POWER PLANT, AT NANCY, FRANCE

The gas, as it leaves the byproduct plant, is cleansed in a dry filter, which differs but little from those already described, and its average composition may be given as follows:

		Per cent.
Carbon dioxide	CO_2	2.87
Oxygen	O_2	0.98
Carbon monoxide	CO	7.46
Methane	CH_4	26.78
Other hydrocarbons	CnHm	3.70
Hydrogen	H_2	48.20
Nitrogen	N_2	10.01
		100.00

It will be noted, in both the cases above cited, that the gas from coke ovens is not unlike natural gas, although lower in methane. At Alsdorf it runs from 340 to 450 B.t.u. per cu.ft., and at Heinitz from 470 to 540 B.t.u. The producer gas generated in the auxiliary plant of the Eschweiler Bergswerk Verein, at Alsdorf, averages only 113 B.t.u.; so it will be seen that the coke ovens furnish a comparatively rich gas.

The situation in the Saarbrücken district is similar to that at Alsdorf, but the field is vastly more extensive, as the distribution system serves 27 mines and aggregates more than 70 miles in main cables, with a network of feeder lines. This is all linked together on the "ring" plan, and any point can be supplied from either the gas-engine plant or the steam auxiliary station at the other end of the district. Originally, each mine or group of mines was served by its own steam-engine plant. The gas engines for the Heinitz station were built by Ehrhardt & Sehmer, of Schleifmühle, near Saarbrücken, and the generators by the Felten & Guillaume-Lahmeyerwerke A. G., Frankfurt-am-Main.

In Fig. 3 is shown the 4000-hp. power station of the Societe Anonyme des Hauts-Fourneaux, Pompey, near Nancy, France, which is practically identical in appearance and in the design of the electric units with the 3000-hp. plant of the Rheinpreussen Colliery, Homberg, Ger-

many, operating on coke-oven gas. The equipment for both was furnished by Haniel & Lueg, mentioned above.

Fig. 1 illustrates one of three Nürnberg gas engines, aggregating 6000 hp., running on coke-oven gas in the power plant of the Powell Duffryn Steam Coal Co., Ltd., at Bargoed near Cardiff, Wales, and a similar plant of the same capacity, but with direct-current generators, is operated by the Luxemburger Bergwerks & Saarbrückner Eisenhütten A. G. at Burbach, near Saarbrücken, Germany, on a combination of blast-furnace and coke-oven gas.

Fig. 4. Koppers Coke Ovens with Byproduct Plant in Background

Power Equivalent of Coke-oven Gases

Taking the gas-power station at Heinitz as fairly representative of advanced German practice in the utilization of coke-oven gas, it may be said that 120 ovens now in service there, with the long coking period of 41 hours and a daily production of 6.7 tons of coke per oven, yield surplus gas to the quantity of 3,600,000 cu.ft. during each 24 hours. This is found, in actual operation as utilized in gas engines driving alternating-current generators, to be equivalent in electric power to about 100,000 kw.hr., or 120 kw.-hr. per ton.

Comparing this with the installation of 560 Koppers ovens made for the Steel Corporation at Gary, Ind., with a coking time of 16 to 18 hours and a yield of surplus gas amounting to about 45,000,000 cu.ft., some idea can be obtained of the enormous power possibilities of the latest byproduct system. By "surplus" gas is meant the quantity available after heating the regenerative ovens, which requires from 50 to 65 per cent. of the whole, and after deductions are made for other minor purposes. Taking as a basis, the figures compiled from all over the world by German engineers, notably those of the Maschinenfabrik Augsburg-Nürnberg, prior to the recent enormous percentage of increase in coking capacity, it is apparent that upward of 2,800,000 kilowatt-hours of electric energy would be available each day of the year, if all the coke consumed were to be produced in modern byproducts ovens; and even this does not allow for reduced coking periods and refinements of practice such as have been introduced at Joliet, Gary, Birmingham and elsewhere in this country. However, it might not be economical to convert all this energy into electric power, as there is usually a good market for much of the gas for illumination and heating in cities or towns; but the surplus for utilization in internal combustion engines would still be large.

The enormous value of the byproducts of the coking operation is also to be considered, and, as the market for these is extended, there will be more and more of a disposition to erect modern plants in place of the older types. Where the gas is to be used in gas engines, the byproduct plant is a necessity; for otherwise the matter carried in suspension and chemically combined with the gas cannot be removed without disproportionate expense. In connection with the origin of the byproduct system, it is interesting to note that an Alsatian coke-maker named Stauf, of Saarbrücken, made practical experiments along this line with a battery of ovens, as far back as 1772.

BYPRODUCT RECOVERY PLANTS

Since that time, and particularly in recent years, a number of effective systems have been developed; among the best known are the Semet-Solvay, Otto Hoffman, Otto and Koppers. A typical plant for the recovery of byproducts, and consequently the preliminary cleansing of the gas, is described by Prof. Chas. E. Munroe, of George Washington University, in his report to the U. S. Government on coke making. First in importance in such plants, are the exhausters, which remove the gas from the ovens, draw it through the mains and coolers, force it through tar scrubbers, where the tar, which exists in finely divided particles in suspension, is removed through friction, and thence lead it to the ammonia scrubbers. These are followed by the ammonia recovery plant, where weak ammoniacal liquor is converted by distillation into concentrated crude liquor or into ammonium sulphate. The gas itself passes from the ammonia scrubbers to the benzol recovery plant, where benzol is obtained by scrubbing it with dead oil. It is then drawn through the dry filter previously described, for the separation of the remaining sulphur and cyanogen compounds. The details and ramifications of byproducts plants vary widely, because the substances obtainable from crude coke-oven gas are quite numerous. So far as the subject of this article is concerned, however, the main object is to strip the gas of everything carried in suspension which would be deleterious to the cylinders or other parts of gas engines, and deliver it at the final dry filter plant with only such chemical compounds as are there readily removable. Fig. 2 is a view taken at a Koppers plant, Oespel, Germany, showing condensers, coolers, tanks, etc.

Additional power from coke ovens can also be obtained by utilization of the waste coke, or coke "riddlings" in a producer especially designed for that purpose. This system will be described in a later article. .

As previously mentioned, the gas is customarily passed through holders, in which it is blended, and then drawn by natural suction to the cylinders of the gas engines. The four-cycle, double-acting type of engine has been most successfully used abroad; and for large plants twin-tandem machines, with heavy fly-wheel rotors in the generators are preferred. Quality, or constant compression, regulation has displaced the quantity regulation originally tried, and with this change there have been removed the principal difficulties which were still encountered after the problem of cleaning the gas had been solved. Trouble with the stuffing boxes, uneven heating of the cylinders, distortion of piston rods, defective ignition systems, etc., which were so discouraging at first and had such a deterrent influence upon similar efforts in this country, have practically been eliminated. Water jacketing and cooling, lubrication, etc., have also been made both effective and economical. In short, the Germans have been entirely successful in utilizing coke-oven gas for power, and there is no reason why Americans should not take due advantage of their experience.

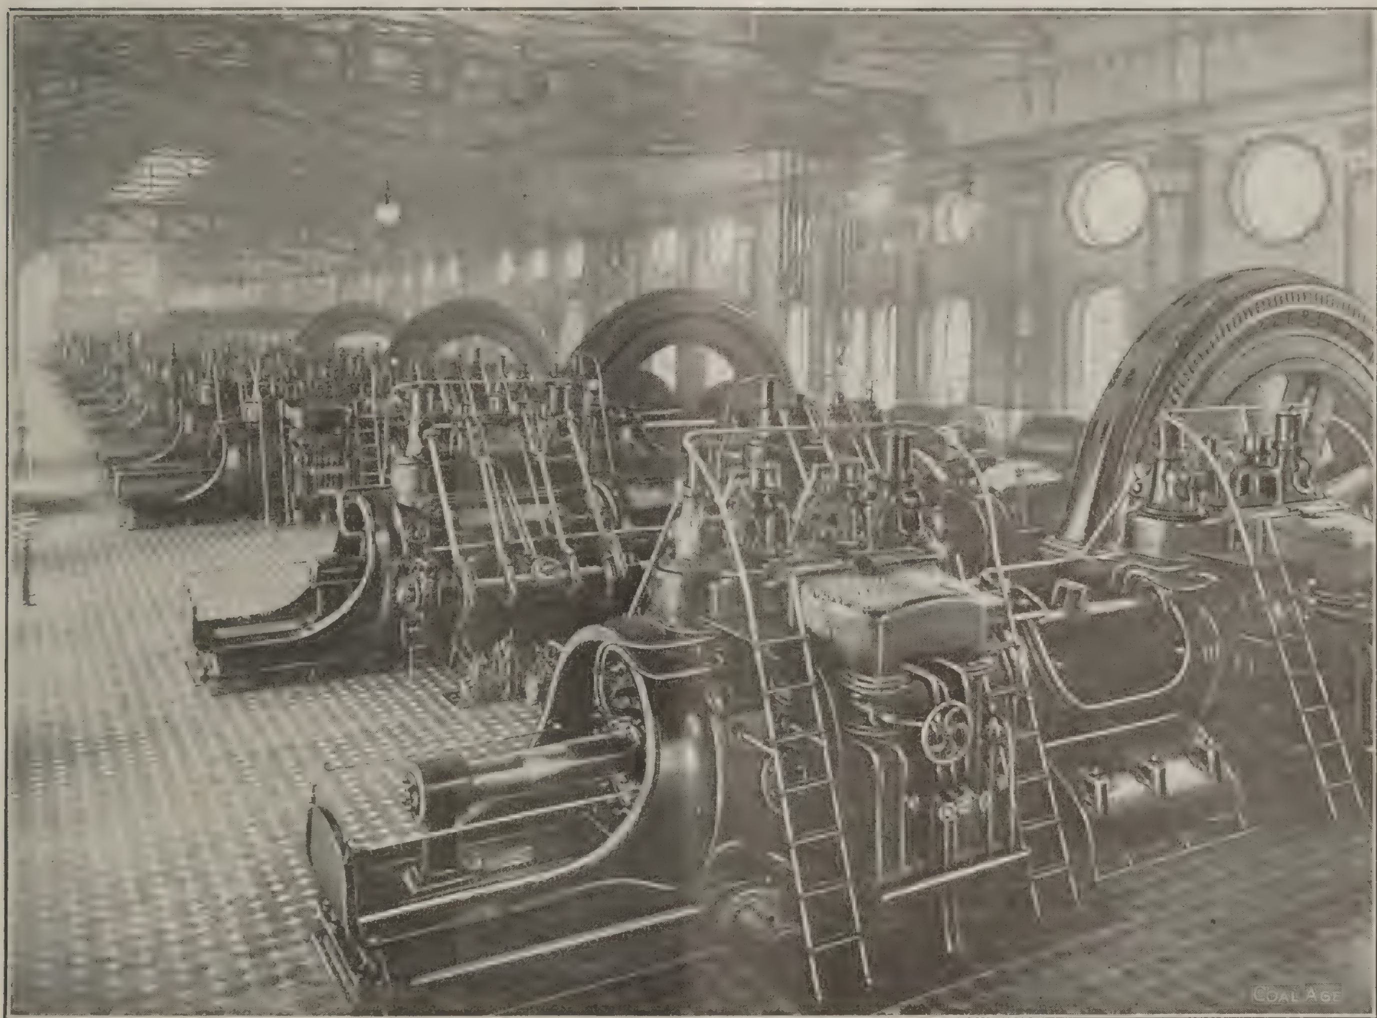

FIG. 5. POWER PLANT USING COKE-OVEN GAS, ESCHWEILER BERGWERKS VEREIN

The successful working of a coal seam depends to a large extent upon the equal distribution of the weight of the overlying strata upon the pillars. Many a seam has been lost for lack of attention to this important detail.

Portable Electric Lamps for Miners

Careful experiments which the Lehigh Coal & Navigation Co. have conducted for an extended period with the portable electric storage-battery system of lighting for mine workers have given such encouraging results that the management has been prompted to take another step forward in the application of this system to the operation of its mines.

The company's electrical engineer, G. M. Kennedy, was recently directed to design a modern charging plant for the storage batteries, which would insure their being charged at constant voltage, and provide means for measuring the consumption of current, so that an accurate account of the cost of operating and maintaining the system would, at all times, be available.

There are several such charging stations in the coal fields at present, but they all receive the necessary current from nearby trolley lines, and as the line voltage on mine-haulage systems usually fluctuates from 250 volts to zero, it can readily be seen that under such conditions no storage battery will operate at a maximum efficiency. By keeping in view the conditions that should govern the recharging of storage batteries, an installation has been designed and completed that will undoubtedly set a standard to be followed by many other coal companies.

The Charging Plant

This equipment is shown in Fig. 1, as temporarily located in the safety-lamp house at the company's No. 5 colliery. As soon as the weather permits, a permanent installation will be made in a brick building, to be erected for the purpose of housing the entire equipment, and it may be well to ignore some of the details of the temporary installation and outline the permanent equipment to be located at No. 5 colliery.

A diagram of the plant, which is of ample capacity for charging 400 cells, is shown in Fig. 3. From the power house, located two miles distant, current is transmitted at 2300 volts, and is stepped down through three 2-kw., General Electric, Type H transformers to 220 volts, and thence transmitted through 1½-in. conduits to the switchboard, which was specially built for this installation by Eynon & Evans, of Philadelphia, Penn. The current passes through a 50-amp., triple-pole switch to a starting compensator, which controls the 7½-hp., General Electric, three-phase, 220-volt motor, running at 1500 r.p.m. This is direct-connected to a 5-hp., 125-volt, d.-c. interpole, compound-wound generator that furnishes the charging current. This power is transmitted through 1½-in. conduits to the switch on No. 2 panel, where one Westinghouse, 150 d.-c. volt meter,

Special Correspondence

Electric lamps, worn by the mine worker and giving a reliable light continuously for more than 12 hours, are being introduced at a number of collieries. The equipment installed at one operation of The Lehigh Coal & Navigation Co. is here described, with special reference to a charging station for the lamp batteries.

one 7½-amp. current meter, and one 5 amp. polyphase wattmeter are provided. These enable the operator to ascertain the exact amount of current that is being consumed and from these data the engineering department will be able to determine the actual cost of operation and maintenance.

There is also provided on No. 2 panel of the switchboard, an automatic reverse

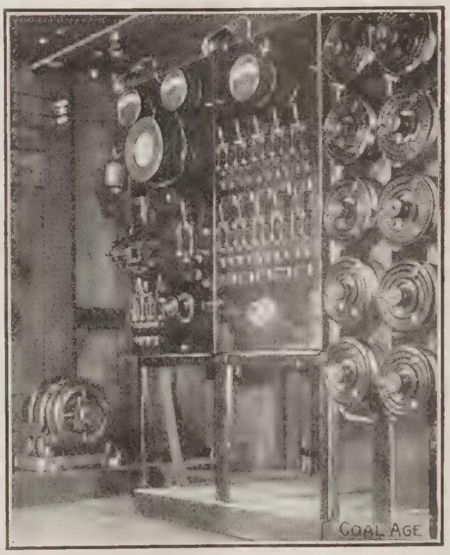

Fig. 1. Switchboard and Charging Motor

current and overload circuit breaker, furnished by the Cutter Co., which automatically opens when the current in the cells reaches a predetermined point, and thus prevents the battery current from flowing back into the generator circuit.

From the generator switch, a set of busbars connects with ten 25-amp. White return-bend switches, each equipped with a shunt coil. On No. 3 panel are 10 wall rheostats, furnished by the Cutler Hammer Co., of Milwaukee, designed to regulate the voltage, so that from 20 to 40 cells may be charged at one time in each of the 10 circuits. The charging current is measured by an 8 amp. meter that is switched into the desired circuit through the 10-circuit ammeter-shunt switch, manufactured for this installation by the Crause Hinds Co., of Syracuse.

Rack for the Batteries

The rack for supporting the batteries while they are being charged, deserves special consideration. As shown in Fig. 2, it consists of a series of shelves built one above the other on an angle of 45 deg., and easily accommodates 400 cells. The most important feature of this outfit is the contact device that runs the entire length of each shelf, and is made of No. 12 gage sheet brass, 1 in. wide. In order to charge one of the batteries, it is only necessary for the operator to push it between any pair of the jaws and it then forms a part of the circuit. By this method, all danger is removed of reversing the flow of current through the batteries, and the tedious work of connecting and disconnecting a large number of wires is obviated. Moreover, the racks always present a neat and clean appearance. The negative portion of the circuit is carried by a No. 6 wire, which terminates at the top of the racks, and from there the current is carried by a ⅜-in. brass rod which connects with each one of the contact strips. The positive leads are carried from the switchboard to the opposite end of the table and are there connected to each one of the ten brass switches.

As is usual in the case of all inventions that have successfully reached the commercial stage, there have arisen many claimants for the credit of perfecting the storage battery to the present efficient form, that now enables miners to use an electric light in their daily work. While some of the coal companies have conducted a number of experiments with storage batteries, their work has been limited to the task of making life and efficiency tests of such storage batteries as the various manufacturers have submitted for that purpose.

It remained for H. H. Hirsch, of Philadelphia, after many years of exacting research, to develop and perfect a battery that has now been accepted by coal-mining companies, as one that meets the rigid requirements of mine work, and there are now in use in the anthracite field nearly 4000 portable lamps of the Hirsch type, manufactured by the Pennsylvania Storage Battery Co., of Philadelphia.

The Hirsch Lamp

The construction of the battery is unique, in that the two electrodes are arranged horizontally and the plates are separated by a substance which is a combination of wood fiber and hard rubber. After a number of experiments directed toward finding a solid electrolyte, a material was found that, when treated with certain acids, formed a gelatinous silicic acid, which sets to a congealed jelly in

a half hour after charging, without adding to the internal resistance of the battery.

The new type of battery measures 2x3x4 in. It is supported by a 1¼-in. leather belt, that either can be slung over the shoulder or secured around the waist, and, as the batteries weigh only 2 lb., the miner is not encumbered in his work.

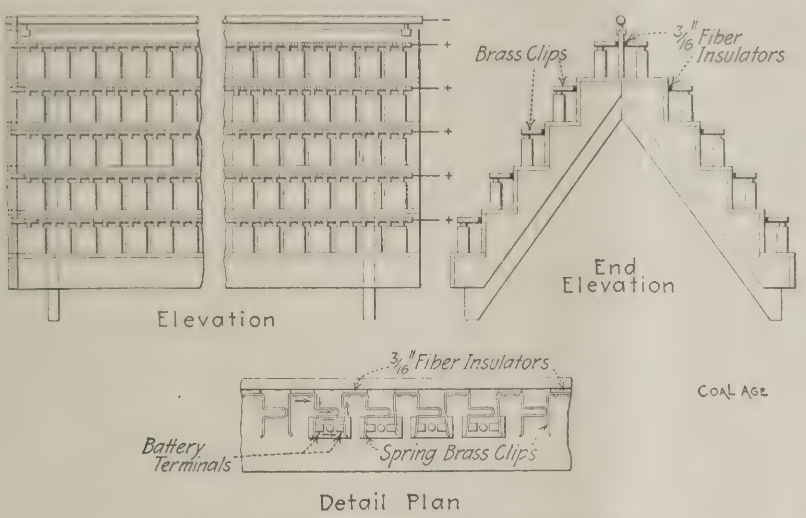

FIG. 2. CHARGING TABLE AND CONNECTIONS

From the battery, a No. 16 brewery lamp cord, with copper terminals, carries the current to the 2-cp. special Mazda lamp, which is secured to the miner's cap, furnished with the equipment. The efficiency of the light is increased by the use of a strong parabolic reflector, specially designed to produce a clear light, without shadows, and is protected from dirt or injury by a heavy glass front.

Constant use of the equipment pointed out several minor defects that were quickly eliminated by the hearty coöperation of miner, employer and inventor, and today it is possible for the miner to work for as much as 16 hours with a clean and reliable electric light furnished from one battery. In fact, on several occasions, batteries have furnished current for as long as 30 hours, and it is the hope of the Lehigh Coal & Navigation Co.'s management that when the batteries are charged under more favorable conditions than those that have hitherto obtained, a much desired increase in the life of the batteries will result, or possibly their weight may be reduced still further. The operation of the plant will be supervised by Harold Ramsey, assistant electrical engineer, who assisted in the design and supervision of the installation.

Advantages and Economy

Up to the present time, this company has furnished its employees with the portable lights free of charge, and once used, no mine worker has desired to go back to the old inefficient, smoky and dirty open light. The electric lamp has been used by the men in parts of the mines where gas was present. Also, it has been of material assistance to the firebosses on their daily tours of inspection, and although they have to carry safety lamps for the detection of gas, they now find the portable electric lights indispensable. It does not require a great deal of foresight to predict that the safety lamp will be used eventually only for the detection of gas, and that before long nearly all mine workers will be equipped with electric lights. The low voltage at which the lamp operates, precludes the possibility of igniting a body of gas by a spark from a loose connection or a short-circuit across the battery terminals, and, as the filament of the lamp will remain incandescent only in a perfect vacuum, danger from that source is quite impossible.

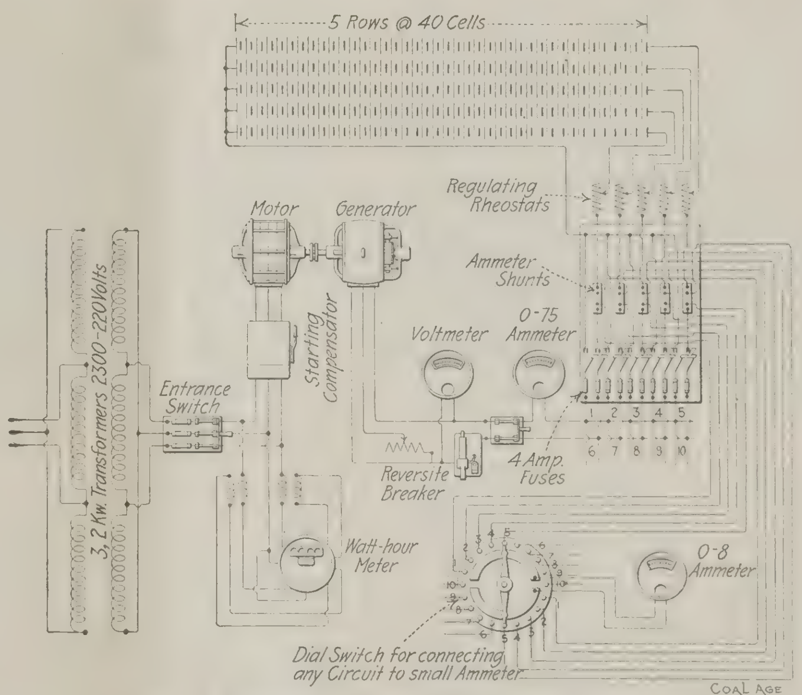

FIG. 3. DIAGRAM OF ELECTRIC CHARGING APPARATUS

From an economic viewpoint, the use of the electric lamp is destined to increase. It now costs a miner from 30 to 40c. per week for oil for the naked light. The same amount weekly will cover the interest on the investment in a portable electric light, and also the cost of maintenance. Even if the coal-mining companies should ask each miner to purchase his own equipment, it would entail no added expense.

Universal use of the electric lamp would relegate to oblivion the dangerous naked light, and thus materially decrease the fire hazard underground, and mark the passing of one of the sources of preventable mine fires. The lamps are being used above ground also, where the danger of causing fires is considerable, and it is now no longer necessary for repair men to use open torches while working in the breakers. Shotfirers have found the batteries adequate for their work, and they are thus provided with an additional safeguard.

In this day and generation, when it seems popular to assail corporate interests, it is a pleasure to record a work on which progressive managers of coal companies have expended both much time and money, so that the burden of the mine workers may be lightened and the mines freed in part of their hazards and dangers.

Experience has shown that it is wise to install electric locomotives of a larger capacity than is necessary to deliver the required draw-bar pull, for if the motor has no reserve power but is only just able to develop the required pull under favorable conditions, then when these conditions are altered, as is sure to be the case at times, the motor is apt to prove unsatisfactory.

Central Station for Colliery Service

By E. B. Wagner*

The proposed electrification of a considerable portion of the Lehigh Valley Coal Co.'s operations in the vicinity of Centralia, Penn., has resulted recently in the construction of a central station at that point. The equipment of this installation is here described in detail.

During the past year, the Lehigh Valley Coal Co. has put in operation the first part of its new central station, at Centralia, Penn. This company has extensive operations in the vicinity, which are widely distributed over a large territory and consequently can be served with steam power, only by a number of isolated boiler plants. The purpose of the new central power plant is to replace the steam-driven hoists, pumps and fans that are operated by the isolated steam plants, with more economical electrically-driven equipment.

The Centralia Colliery was selected as the site for the new power station, not only because it is most centrally located, but also because it is the receiving point for coal from the numerous shafts and slopes in the neighborhood. There is thus insured a plentiful supply of cheap fuel, obtained directly from the nearby breaker. To take care of the increased steam consumption at this point, due to the centralization of power supply, the erection of a new boiler plant has been started and two batteries of Stirling boilers have been installed, provisions being made for more to follow as necessity arises. A working steam pressure of 150 lb. is maintained.

The power house is of reinforced concrete, pilaster construction, with 4-in. curtain walls. Large size Fenestra steel window frames in each panel give a well lighted interior. The plant is equipped with a hand-operated 18-ton crane. Owing to the natural contour of the ground it was possible to build a retaining wall just behind the steam cylinders of the engine, thus forming a pipe way, in which are placed the steam and exhaust lines. The wall at the west end of the building was made of temporary construction so that an extension to the building could readily be made.

A general floor plan of the plant is shown in Fig. 3. The large foundation is for a 22 and 36 x 36 in. cross-compound corliss engine, running at a speed of 107 r.p.m. Directly connected to this engine is a 500 kv.-a 2300 volt three phase, 25 cycle alternator. The low frequency was adopted because the power generated will be used exclusively for hoisting, pumping, fan and haulage work, in which low speed motors can be employed to advantage.

In the northwest corner of the building is located the switchboard, with the electrolytic lighting arresters in the rear. Directly in front of this is a 75 kw. 125 volt motor-driven exciter set, operated by a 112 hp., 2200 volt, 750 r.p.m. induction motor, with s uirrel cage rotor. At the side of the motor is the autostarter. The steam-driven exciter is placed behind the motor-driven unit and consists of a 13x14-in. side crank engine connected to an 80 kw. 125 volt generator, running at a speed of 255 r.p.m. Both the exciters are shunt wound and are of sufficient capacity to supply three 500 kv.-a. generators. All generator and field wires are run in conduits placed under the floor, pot heads being placed on the end of the 2200 volt cables and condulets on the direct-current wires.

The switchboard is built of black marine-finished slate panels, 90 in. high and arranged in the following manner: Starting at the right, panel No. 1 is a double exciter panel having mounted on it two double-pole main switches, two d.-c. ammeters, a d.-c. volt meter and plugs and two field rheostats. Panel No. 2 has an oil switch equipped with an overload release for the motor-driven exciter set, and on its upper section is mounted a Tirrill regulator. Panel No. 3 is a generator panel and is equipped with an a.-c. ammeter and switch, a.-c. volt-meter and plugs, d.-c. field ammeter, indicating polyphase wattmeter, field switch, rheostat handle, main oil switch and integrating polyphase watt-hour meter.

Panels Nos. 4 and 5 are blank generator panels. Panels Nos. 6, 7 and 8 are feeder panels, each being equipped with one ammeter and automatic oil circuit breaker with inverse time element relays. At the right of the switchboard, is a swinging bracket holding synchroscope, frequency meter and power-factor meter. Following standard practice, no circuit breakers are placed on the d.-c. exciters or alternator main switches.

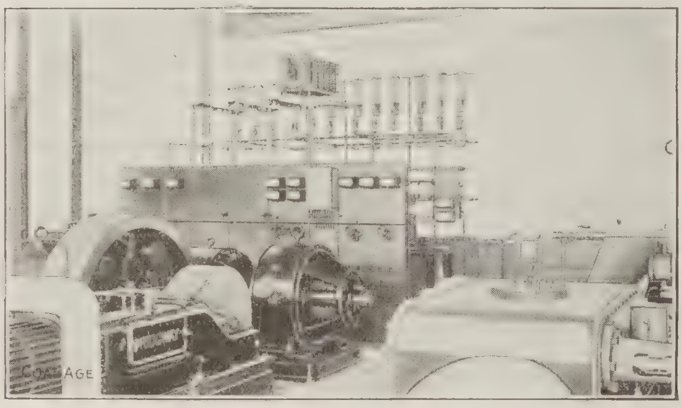

Fig. 1. Northwest Corner of Power Plant

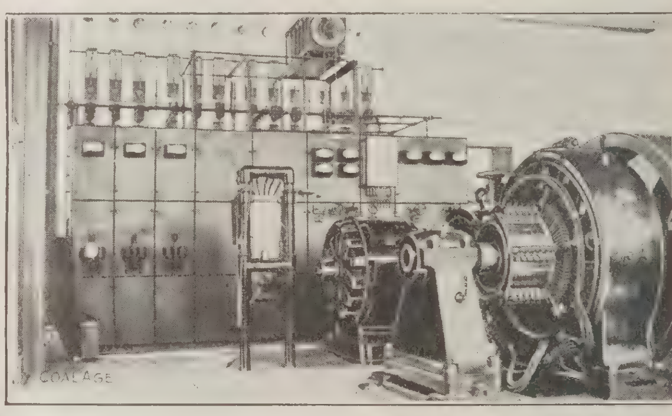

Fig. 2. Exciters and Switchboard

Figs. 1 and 2 show interior views of this central station. Fig. 1 gives a general view of the exciter and switchboard. It will be noted that the alternator field rheostat is shown mounted on a pipe framework directly over the generator panel. In the rear, and above the top of the panels, the choke coils and disconnecting switches are mounted on a pipe framework, while just above them are the wall insulators, through which the 2200-volt feeders pass to the wire tower outside the building.

The method of mounting the autostarter for the exciter motor is plainly shown in Fig. 2. This mounting consists of a 3-in. gas-pipe framework with a triple - conductor varnished - cambric cable running up inside each vertical pipe. The elbows at the top are types *LR* and *LL* condulets, the wires coming out through the porcelain bushings and entering the starter.

*Electrical engineer, 56 North Washington St., Wilkes-Barre, Penn.

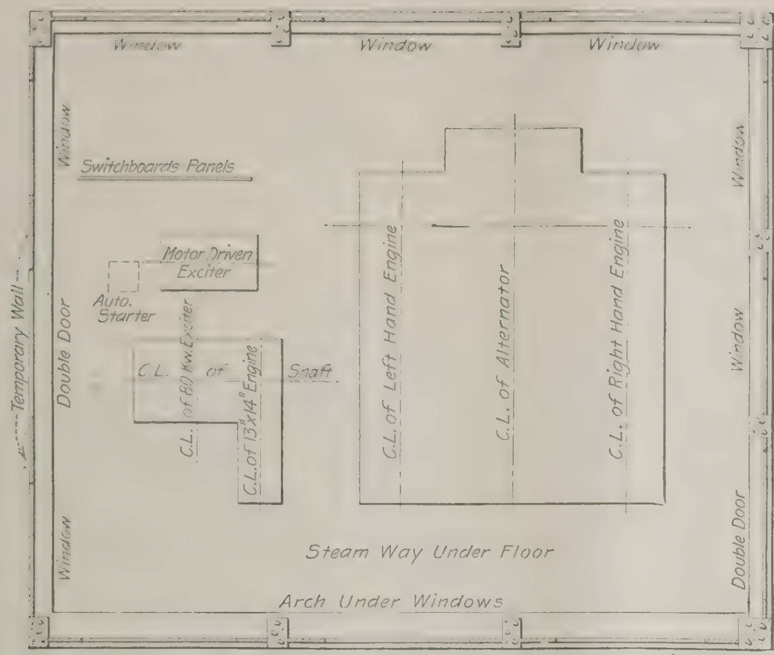

FIG. 3. GENERAL PLAN OF STATION

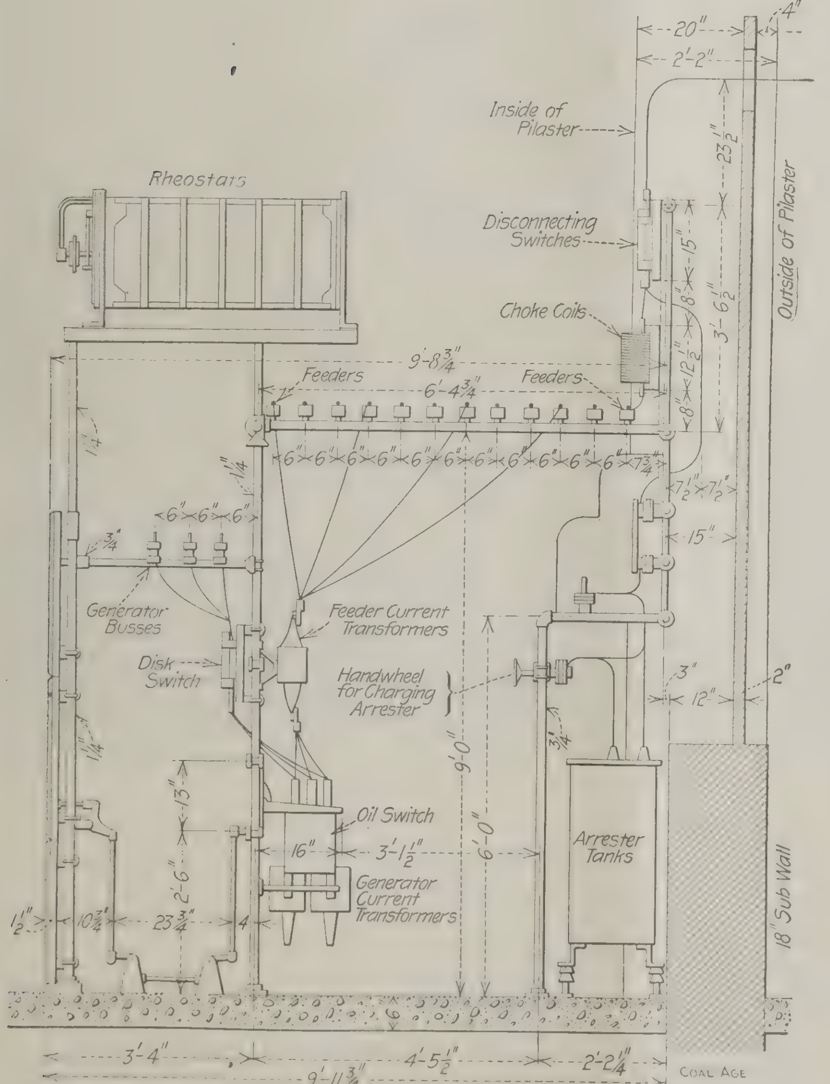

FIG. 4. SIDE ELEVATION, SWITCHBOARD AND CONNECTIONS

The insulators supporting the feed wires which run from the choke coils to the oil switches, are shown fastened to the horizontal pipe framework in Fig. 5. These were made from porcelain insulators, such as were used on the pole line, cemented to the wood screw of a gem wire clamp. A satisfactory and inexpensive insulator was thus obtained.

An end view of the switchboard is shown in Fig. 4. From this, a good idea of the general arrangement of the apparatus may be obtained. The space of 3 ft. 1½ in., from the oil switch tanks to the lightening-arrester framework, is enough to allow the attendant to enter and charge the arresters. There is also ample room to permit his reaching the

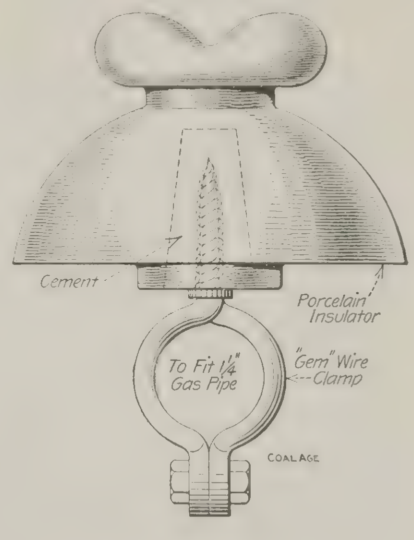

FIG. 5. DETAIL OF INSULATOR

rear of the switchboard panels if necessary, without danger of coming in contact with any of the high-tension apparatus.

For lighting the power house, the ceiling was divided into nine squares and a lighting unit consisting of one 150-watt, 115-volt, wire-type Tungsten lamp with Holophane focussing reflector was placed at the center of each square. In order to clear the crane, the mounting height was made about 22 ft. above the floor. The ceiling and walls of the building are painted white so that an illumination of from 3 to 3½-foot candles is obtained, which is ample for this class of service. A double-pole, double-throw switch is provided so that the lamps can be connected either across the 115-volt side of a small transformer placed behind the switchboard or to the exciter buss bars for lighting when the alternator is shut down. The flickering caused by the low frequency is unnoticeable in the case of the Tungsten lamps in the power house but where carbon filaments are used it is plain enought to be objectionable.

Explosion at Welch, West Virginia

By H. J. Brook*

The Jed mine explosion resulted in the death of 81 men. Thirteen were rescued, but one soon succumbed to his injuries. The mine generated gas but open lights were used. Otherwise the mine was excellently conducted. In 1908 the chief mine inspector tried to compel the use of safety lamps but was overruled by the county court.

*Consulting engineer, Welch, W. Va.

Jed mine, operated by the Jed Coal & Coke Co., is located two miles from Welch, the county seat of McDowell Co., W. Va. It is situated on the Tug River and ships its coal over a branch of the N. & W. R. R. The mine explosion which occurred in that mine on Mar. 26 at 8:10 a.m. was another of those startling surprises which the coal operator often experiences when he feels most secure, having taken due precaution against any such an occurrence by the employment of competent men to look after the general safety of the mine and miners, and having followed willingly every suggestion of the mine inspector.

An Uptodate Mine

The coal worked is the No. 3 or Pocahontas bed, and is about 5½ ft. thick in this locality. The draw slate is from 12 in. to 18 in. thick and can generally be held up in the rooms until they are driven up their full length. Draw slate is taken down in all entries, but held in place by timber in the airways and rooms.

The mine is laid out on the four-entry system and is projected for two distinct and separate mine sections. It will be operated eventually with a separate air system for each section and divided throughout by a 200-ft. barrier pillar. Each separate district is subdivided into panels. At the time of the explosion the mine was ventilated by two air splits, and the fan was exhausting.

Manner of Digging Coal

The coal is dug by machines, the undercutting being done mostly at night. It is shot and loaded out during the day. R. C. Niediffes, a certificated fire boss, had charge of the night shift and he examined the mine every day before the men entered. He made report that every place was safe on the morning of the explosion.

The night shift quits at 4 a.m. and the day shift goes on at 7 a.m. As the coal which is to be removed, has all been undercut, the first duty of the miners on arriving at the working face is to place the "breaking" shots and these are fired therefore at about the same time throughout the mine. The two rib shots follow as soon as the coal from the first shot is cleaned up. No two shots are fired at once in any one working place. Three shot firers, who are certificated fire bosses, fire all shots, each taking a separate section of the mine. They use batteries for this purpose. The mine is known to give off gas, but not in dangerous quantities, and open lights are used. Where necessary, the mine is sprinkled to prevent its becoming dangerous from accumulations of coal dust. During both day and night shifts the mine was well guarded by competent mine officials.

The Jed mine, which normally employs about 125 men, was, fortunately, at the time of the explosion, working shorthanded. Owing to Saturday, Mar. 24, having been pay day, only 93 miners and company men were in the mine at the time of the explosion. The check system used at the mine shows exactly what men are below the surface at any time. Twelve men nearest the shaft bottom escaped practically unhurt, and were hoisted on the cage immediately after the explosion.

Jed Colliery, McDowell County, W. Va., Shortly after the Explosion

Surface Evidences of Explosion

The main shaft is 280 ft. deep and the mine is ventilated by a large Capell fan, built so that it can be reversed when necessary. The explosion was not heard far from the mine, and the report, which was of short duration, resembled the blowing

off of a boiler. At the same time black smoke issued from the fan and hoisting shaft. Neither the main shaft nor any of the hoisting apparatus was damaged by the explosion. The fan was crippled it is true but nevertheless for a while it was kept running. After all hope of rescuing any of the 81 entombed men had been abandoned, the fan was stopped, and the three damaged blades repaired, so as to make its operation more effective.

THE VILLAGE OF JED

CROWD AT MINE LANDING

PREPARING FOR THE DEAD

RESCUE WORK

Immediately following the hoisting of the twelve men who escaped, a rescue party, comprised of O. M. Knouff, superintendent, J. Harvey Williams, mining engineer, Fred Henrichs, outside foreman, J. S. Henry, mine foreman, and three others, were lowered into the mine and proceeded as far as the mouth of Second Main Entry, about 600 ft. from the shaft, at which point they found the door-tender, who was badly hurt. He was sent up and taken to his home, but died shortly afterward from internal injuries. The men encountered blackdamp and could proceed no further without the aid of more men and supplies to restore the ventilation. They returned to the surface where they were met shortly afterward by William Nicholson, the state mine inspector, in whose district (the 11th) the mine is located. He was accompanied by P. A. Grady, inspector of the 12th district. These men were about to descend the shaft mine of the Middle States Coal and Coke Co. on a joint inspection, when word reached them, and they lost no time in covering the four miles which separated them from the scene of the disaster.

After the arrival of the inspectors, according to the custom, the mine was taken in complete charge by them. They showed themselves to be most efficient in their duties. They had the assistance of Edward O'Toole, general manager of the United States Coal and Coke Co., and J. M. Vest, superintendent of the Standard Pocahontas Coal Co., both of whom responded quickly, bringing men, tools, safety lamps and other safety devices. Edward O'Toole brought with him two men fully equipped with safety helmets. The inspectors soon organized the men into parties for the restoration of ventilation and the recovery of the dead. It was soon discovered that there was little hope that any of the entombed men could be alive.

The local inspectors were joined by Inspector Arthur Mitchell of the 10th district, who arrived at 5 p.m. on the day of the explosion. He took charge of the night relief crew. Federal Mine Rescue Car No. 7, which was *en route* to Huntington, arrived at the mine at 2:30 p.m. in charge of Mr. Burke. He and his assistants entered the mine in company with the two men from Gary, all equipped with safety helmets. They were unable to accomplish much or cover much of the mine, owing to the heavy falls of slate which made it difficult to travel with so heavy a burden.

Later the State and Federal officials, joined by Chief Inspector John Laing and State Inspectors James Martin, H. Y. Muir and Lance B. Holliday, arrived and George S. Rice, James W. Paul, M. Roudenbusch, and Dan Davis, of the Bureau of Mines, also came to aid in the rescue work and in the investigation. Both State and Federal officials will leave representatives on the ground to make a thorough examination of the mine that the cause of the explosion may be determined.

Left Entries Most Affected

It is generally supposed from the resulting condition of the mine that the explosion originated in First butt-heading left off Second main entry. This supposition is based on the fact that the air traveled to the left butt-headings and thence up the Second main airway. On this side the explosion occurred. Moreover, the bodies brought out from the First left butt-entry and vicinity were the most badly burned. The other split traveled up the right-hand butt-headings off the First main entry and thence to the face of the latter and returned by way of the First main airway. Three of the men working in the Second butt-heading right, which is ventilated by this split, succeeded in escaping from the mine. The other nine men who escaped were also in same split but near the shaft.

Up to Saturday night 72 bodies had been recovered from the mine. Considerable difficulty was encountered in this work, owing to the blocking of the roads by heavy falls of slate and the rebratticing needed to restore ventilation. Most of the stone stoppings on the butt-entries and the concrete brattices on the mains were blown out along the course of the explosion.

Some of these bodies were covered by heavy falls of slate, which had to be removed before they could be recovered. During this rescue work in some places portable electric lights had to be used and the safety lamp discarded on account of meeting with explosive firedamp. On one occasion, by the use of these lamps, six bodies were recovered, which could not have been safely removed had safety lamps been used.

W. M. Leckie, general manager of Jed mine, was away at the time of disaster, but returned as soon as word reached him. He immediately did everything he could to relieve the situation. It is expected that by next Tuesday the mine will be in a condition that a thorough examination may be made to determine the cause of the explosion.

[Mr. Brook fails to call attention to a point of great interest in connection with this disaster. The coal beds continuously dip toward Welch from the east and at Jed much gas is encountered. Even at Vivian where the bed still outcrops to the surface at an elevation of about 30 ft. above the valley, a gas explosion recently occurred. J. G. Boyd, who was mine inspector of the 11th district in 1908, called attention in his report to the condition of the Jed mine, saying that it was not as safe in his judgment as it ought to be. In accordance with Sec. 14 of the mining law, which required all mines generating gas in dangerous quantities to be worked exclusively by locked safety lamps, he demanded that within a month open lights should be completely excluded from all parts of the mine. The general manager, Wm. Leckie, finally appealed the matter to Jas. W. Paul, then chief of the department of mines, and now in charge of the rescue work of the Federal Bureau. For a while Mr. Leckie favored conceding the demands of the department and even sent a telegram ordering the safety lamps, but he later notified the inspector of his change of opinion. J. W. Paul, D. R. Phillips and P. A. Grady then reëxamined the mine and as a result suspended operations. Finally the court granted an order for the reopening of the mine.—Editor.]

A Comparative Test for Air Drills

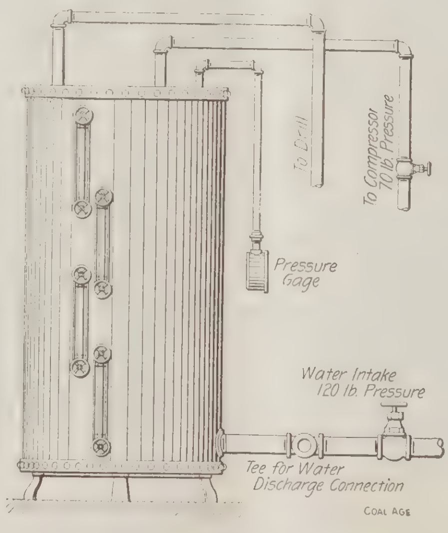
Special Correspondence

Nearly all users of drills find it necessary or desirable from time to time, especially when about to undertake important new work or when about to purchase a large number of drilling machines, to determine the performances and relative efficiencies of the various types of drills found on the market. The arrangement described in the following paragraphs has been satisfactorily used in conducting such tests on different forms of compressed-air drills.

As shown in the illustration, a vertical air receiver is connected to the compressor line by a 1-in. pipe, fitted with a globe valve, and a 1-in. outlet pipe is led from the receiver to the drill. Water gages are placed one above the other throughout the entire height of the receiver, and a pressure gage is supplied. At the bottom of the receiver a 3-in. pipe with globe valve furnishes a water supply, and between the receiver and intake valve a tee connection is provided as a discharge.

Before starting the test, water is allowed to flow into the receiver until it is just visible in the lower gage, and a chalk mark is made opposite this level. The receiver is then filled with air at the desired pressure, the air shut off and the test begun. As the drill takes air from the receiver, the operator maintains a constant pressure by regulating the water valve. Simultaneously with the stopping of the machine a chalk mark is made at the water level then shown by the gage and the water drained off in preparation for the next test.

The distance between chalk marks, depth of drilled hole and time of drilling are noted. The cross-section of the tank being known, the distance between the chalk marks makes it possible to find



Air Tank and Connections

the volume of air used, at the given pressure, and from these figures the amount of free air can be computed. A convenient form for arranging the data and results of the test is shown in Table I. The average values obtained for the last three items in the table give the information that is usually desired in this connection.

It may happen, however, that in spite of the control provided by the water supply, the air pressure will decrease during a test. In this event, the amount of free air used may be calculated as follows:

Let

P = Initial pressure,
P_1 = Final pressure,
B = Height above initial water level to top of receiver,
A = Cross-sectional area of receiver, in sq.ft.,
R = Rise of water in receiver, in ft.,
H = Atmospheric pressure.

Then each foot rise of water in the tank represents the consumption of A cu.ft. of air and if the pressure had remained constant at P, the volume of free air used would have been given by

$$V = RA \times \frac{P+H}{H}$$

However, the expansion of the air that remains in the receiver, from pressure P to P_1 represents the consumption of a volume of free air equal to

$$V_1 = A\,(B-R)\left(\frac{P+H}{H} - \frac{P_1+H}{H}\right)$$

and the total amount of free air used is then $V + V_1$.

[It may prove more simple to let V represent the initial amount of free air in the tank at pressure P and V_1 represent the final amount of free air at pressure P_1. Then

$$V = AB\frac{P+H}{H}$$

$$V_1 = A\,(B-R)\frac{P_1+H}{H}$$

and $V - V_1$ will give the amount of free air consumed during the test.—ED.]

Winners in First Aid Contest

At a competitive first-aid contest, held in Connellsville, on Mar. 27, the Phillips Mine first-aid squad, of Uniontown, Penn., under the superintendence of W. J. Culleton, made a perfect score of 100 per cent. efficiency, in a series of difficult events. This particular team will represent the H. C. Frick Coke Co. at the National Meet of First Aid to the Injured, to be held in Washington, D. C., at the invitation of Major Charles Lynch, of the United States Army.

The Phillips team competed with 14 of the best squads of the Frick company, and it is therefore considered a great distinction to have made this remarkable record. The members of the squad are: Captain Harry A. Sigafoes, John Birsky, Andrew Secosky, William Shaw, Elmer Moody and Walter R. Kuhns.

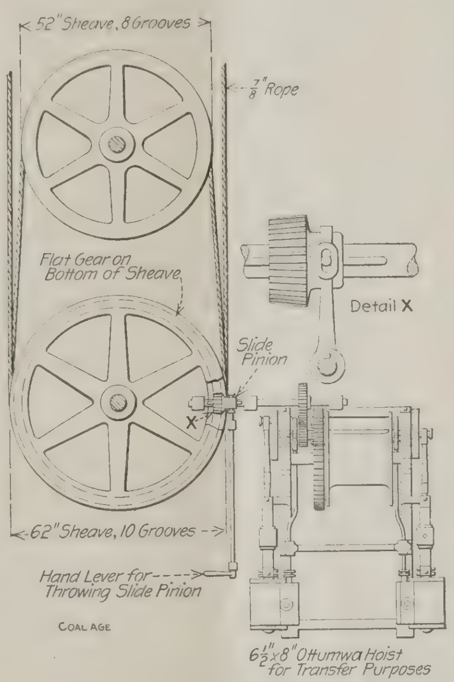
Combined Gravity Plane and Hoist

BY JOSEPH DANIELS*

A number of mines in the Roslyn district of the State of Washington are located in the hills at some height above the tipples and railroad tracks. The coal is usually sent down to the tipples by an engine, or gravity, plane. At the Roslyn Fuel Co.'s No. 2 mine, the gravity plane is 3400 ft. long, with an average grade of 14½ per cent., and crosses three ravines on timber trestles. From the mouth of the mine tunnel, the plane has three rails to the midway point. The pass-by here is 120 ft. long and below this point a single track runs to the tipple. The track gage is 30 inches.

*Department of mining, University of Washington, Seattle, Wash.

Cars are handled in trips of ten. The weight of an empty car is 825 to 850 lb.; the weight of the average loaded car is 2400 lb.; the size of the rope is ⅞ in.; and the time required to hoist or lower a trip is 2½ min. A set of gravity-plane sheaves is used to lower the cars to the tipple, but the usual arrangement has been modified, as shown in the illustration. A gear wheel is fastened to the under side of the larger sheave. This gear meshes with a small pinion, mounted on a shaft, which is driven from the main gear of the hoisting engine, as shown in the sketch. The small beveled pinion is thrown in or out of mesh by being moved back and forth along the shaft, under the control of a hand lever, located



GRAVITY SHEAVE AND HOIST

conveniently near the throttle and operating levers of the hoisting engine. This latter is a small second-motion, friction-clutch, single-drum engine, used for transfer purposes at the mouth of the tunnel.

Purpose of Arrangement

The purpose of this arrangement is to enable the sheave to be driven when occasion demands; that is, if, for any reason, it is necessary to hoist the empty cars from the tipple to the tunnel mouth and there are no loaded cars available for sending down, the engine is started up and by throwing the pinion in mesh with the large gear, the sheave of the gravity arrangement is made to act as a drum for hoisting purposes. The device is also useful in case of breakdowns and derailments at any point along the road, when it may be used for putting the cars on the track, hoisting ditched cars out of the ravine and in many like contingencies.

Strike Situation in the Anthracite Field

SPECIAL CORRESPONDENCE

Anthracite mine operators are accepting with equanimity, the suspension ordered by officials of the mine workers' union. They are making no effort to mine coal and apparently will not, for some time at least, endeavor to induce any of the men to return to work. There is a general feeling on both sides that within the month an agreement will be reached and that work will be resumed within six weeks. If this happens neither mine operators nor mine workers will suffer from the suspension of work, as it will merely give the consumers time to use up much of the stock they have stored in anticipation of a strike, and make the demand for new supplies so general that fairly steady work will be assured for the summer.

Had the mine workers decided to renew their former contract for three more years, thus obviating a suspension, there would still have been a lack of work for a period about equal to the probable length of the present shutdown.

If the operators decide to offer the men a flat increase of 10 per cent., and ignore their other demands, most of the mine workers will be eager to accept these terms and return to work. Among the leaders, however, there is a great desire to fight for a recognition of the union as well as an increase in wages. Coal operators are unanimous in stating that while they might be willing to grant a 10 per cent. increase they will never agree to recognize the union, and they predict that if the miners' leaders insist on this point, then a long and bitterly fought strike is certain.

It was at first intended to submit whatever offer the operators finally made, to a referendum vote, permitting all the mine workers to express their individual decision on the question of accepting or rejecting the offer. Now, however, this plan has been changed. The miners' leaders announce that any offer will be submitted to a convention. This convention will be composed of delegates elected by the union locals, and the non-union men, who are in the great majority, will, of course, not be recognized. It is natural to expect that the delegates at such a convention will be guided largely by the advice of their leaders, and if the latter insist upon holding out for recognition of the union, as well as an advance in wages, then it is almost certain that the convention will reject the offer of the operators and follow the dictates of their leaders.

Some of the coal companies have been bringing men into the region from outside, but these are being used so far only to guard the collieries.

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Freezing Method of Shaft Sinking

The following is taken from Ad. Breyre's report in the Annales des Mines de Belgique, book, LVI. Entitled "Sinking of Shafts by Freezing Method":

Considered by itself the process of freezing has on the whole, received few modifications since its first introduction; it remains in its broadest lines just as Poëtsch utilized it in 1883 in the Archibald shaft at Schneidlungen. On the other hand, the development it has taken has extended its applicability since that time to a degree that could not have been foreseen by the most optimistic, several years ago. When in 1898 the shaft at Harchies, belonging to the mines at Bernissart, was sunk by freezing to a depth of 774 ft., the attempt was rightly regarded as quite bold, for in the 15 years of the existence of the process, this shaft was the first to attain like depth; before that time they had not exceeded 410 ft.

Today applications to 656 ft. of depth are frequent. In Belgium a depth of 1000 to 1083 ft. was actually attained at Levant-du-Flénu, and in a greater part of the shafts being sunk in the Campine district of Limburg, the depth to which freezing extends approaches or exceeds 1312 ft. (400 meters).

In Germany the two shafts of the Lohberg Works which the Deutscher Kaiser Co. has established near Binslaken have attained a depth of 1361 feet.

Silesian Mining Methods

Special Correspondence

In northern Silesia the coal of the thick seams is developed by narrow stall workings driven in the lower benches of the bed. Final recovery is effected by retreating panel methods, the whole bed being extracted. Sand filling is used sometimes to replace the lower benches before the upper part of the seam is attacked.

The following is an abstract from a paper, by Berent Conrad Gullachsen, entitled the "Working of the Thick Coal Seams of Upper Silesia." The paper was presented at the meeting of the North of England Institute of Mining and Mechanical Engineers.

In the upper Silesian coalfield the workable seams amount to the great thickness of about 623 ft. and what are known as the Suddle strata contain some five to eight workable seams of from 5 to 32¾ ft. in thickness, which together give nearly 98½ ft. of workable coal, chiefly suitable for steam and household uses. Fig. 1 is a section of the strata from Zabrze to Myslowitz. The average thickness of the coal measures is 23,130 ft., the percentage of workable seams being 3.2 in the Crzescher, 11.7 in the Suddle, and 1.9 in the Rybnik strata.

Preliminary Working

In all cases the places are nearly 10 ft. wide and 6½ ft. high, except the cross-cuts, which are only 6½ ft. in width. Bore-hammers driven by compressed air, are used for driving the places; and gas being practically unknown, explosives, chiefly powder fired by fuses, are used. Very little timbering is required, as the coal is generally hard, and forms a good strong roof.

The general method of working is as follows:—When the drift reaches the seam, two headings usually 10 ft. wide and 6½ ft. high are driven water level with a coal pillar 32¾-ft. wide between them. Crosscuts are driven between these headings at 88½-ft. centers. Traveling ways and inclines are driven directly up the pitch, the first serving as a return airway for the second. They are separated by square pillars measuring 32¾-ft. in the clear between headings and crosscuts. From the incline of one pair of steep headings to the traveling way of the next pair is 256 ft., measuring from center to center. Opposite every crosscut on the traveling way, a 10-ft. stall is driven parallel to the main ground level, but as the system is a retreating one the last stall is driven first. The distance from one ground level to the next is 328 ft. The stalls are driven from the traveling way completely through to the next incline, crosscuts being cut from stall to stall every 88½-ft.

Working on The Retreat

When the first stall is extended to the required limit a block of coal at the end is attacked. A pillar 6½-ft. wide is left near the fallen workings adjacent, to protect the workmen, and a wide crosscut or short room is driven up the slope 20 ft. wide.

The 6½-ft. pillar separating the mine from the caved area is here called the "barrier" pillar for lack of a better name. The barrier is removed later if possible. Retreating work is commenced either at the boundary, or at old workings; and, as the working always retreats and descends, the coal is thus gradually worked out toward the ground-levels. Fig. 2 shows the method of working a district. As the barriers are often from 26 to 32¾ ft. in height, they are the most difficult portion of the coal to secure, and consequently much of it is often lost, especially where the roof is poor—the loss amounting in many mines to between 10 and 18 per cent. By sandfilling the gob, however, this loss is reduced to between 3 and 5 per cent.

The coal on the retreat is worked by two methods. That shown in the upper half of Fig. 3 is the form most generally employed. The coal is first undermined, then heavy charges of powder

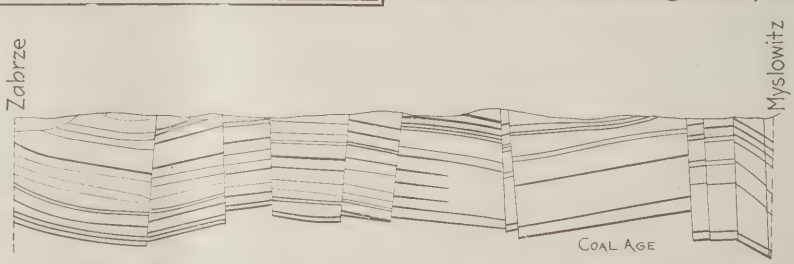

Fig. 1. Cross-section of the Badly Contorted Upper Silesian Coal Field

are put in near the roof, and large quantities of coal are brought down. The method shown at the foot of Fig. 3 is only adopted in cases where the coal is soft and liable to break away, and in the case of a weak roof.

Fig. 4 shows the general method of timbering. When the pillars are worked out, as much timber as possible is drawn, but it is usual to leave the side props, *a, b,* as a protection during the working of the barrier at the side of the next lift. To make these the more apparent they are marked in solid black. The posts which sustain crossbars are shown in the appropriate places but they could not of course be seen in a correct plan view.

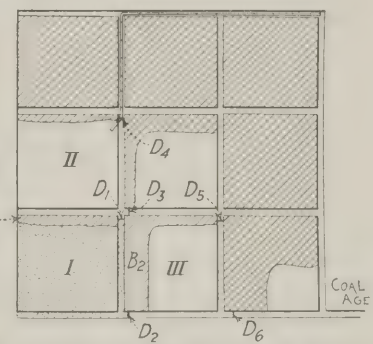

Fig. 7. Complete Sand-filling Plan

Much of the timber has to be left in, especially in case of sand-filling.

When it is desired to extract the pillars rapidly from a district, the method shown in Fig. 5 is employed. Half-way between the inclines, that is 164 ft. from each, a third incline is driven from one level to the level above. At the top of this incline ten-foot stalls are set away on both the right and left-hand sides, one pillar 32¾ ft. in width being left to protect the incline top, this pillar being worked out last. Thus, this middle incline is used for the extraction of three lifts, which, each being about 32¾ ft. in width, give a total of 98½ ft., leaving 114¾ ft. of coal on each side to be won from the other two inclines. In this manner the district is rapidly worked out. The middle incline also serves the purpose of ventilating the workings.

Partial Sand Filling Method

Sand-filling is now being employed more or less extensively in the majority of the thick coal mines of Upper Silesia. It is especially advantageous where spontaneous combustion is prevalent, and in mines which are worked under towns, railways, rivers, etc. There are two methods of sand-filling. In one the coal is partly and in the other the coal is wholly replaced by sand.

The former method as will be seen from Fig. 6 consists in making barriers of sand, 49 ft. in width, on both sides of each district. In order to do this a gangway is started from the ground-level, at a point 41 ft. from the traveling way, and, after being driven to the rise for a distance of 32¾ ft., stalls are set away right and left, and driven 24½ ft. in both directions, thus forming a face 49 ft. in length, which is then worked off in ascending slices. When the face has advanced some 49 to 65½ ft., a small incline-wheel is put in, and the coal is run down the incline to the level, the wheel being moved forward as the face advances. When within 32½ ft. of the boundary of the panel, the place is stopped and a connection made with the incline, and along this gangway the sand-filling pipe-line is laid, and carried to the top of the worked out area. Dams are now built at all entrances, and when they are completed sand-filling is commenced, and carried on until the entire area is filled up. A second barrier is formed in a similar manner at the other side of the district. The area of coal remaining between the two sand-barriers is now removed by the general method of working.

Sand Filling By Slices

In the working of beds from 26 to 32¾ ft. thick the coal is entirely replaced by sand. In Fig. 7, the seam is worked in two slices, the pillars being worked out in an ascending order. The coal is first abstracted from pillar No. 1 in the usual manner, the pillar being about 32¾ ft. square, and should the seam be 32¾ ft. thick, the lower half only is worked. A barrier of coal, B_1, about 10 ft. wide is left, and dams D_1, and D_2 built, the sand-filling pipes being brought through the top of dam D_1 and sand filled into the worked out area. Pillar No. II is then worked, together with barrier B_1. Dams D_3, and D_4 are built, the sand-filling pipes being brought through the top of dam D_4, and sand filled into the worked-out area. At the same time as these arrangements are being carried out, pillar No. III is being worked, by a place 19¾ ft. in width, the barrier B_2 being left. Concurrently with the removal of the main part of pillar III, the barrier pillar of panel II is removed. Dams D_5 and D_6 are now built, and this lift is likewise filled with sand. Thus the work proceeds in a diagonal line towards the incline, and when all the pillars in the district have been removed and replaced by sand, the remaining overlying half of the seam is worked in precisely the same manner.

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

Quite a few years ago, when Charles F. Huber was a student at the Anthracite Mine Managers' University (now commonly called the Pottsville High School), he decided that when he grew up, he would get a job as boss pilot of a great coal company.

Just how to accomplish this laudable aim was not quite clear, until one day the teacher made each pupil memorize the maxim: "A Rolling Stone Gathers no Moss."

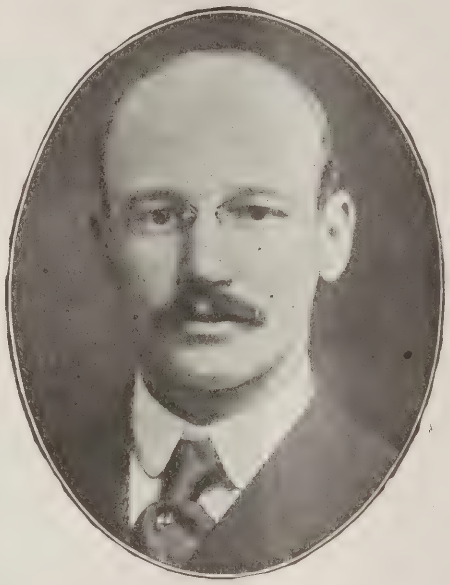
Now, Charles thought a little moss would not only relieve the sombreness of the landscape, but that it might prove useful as well as ornamental. He accordingly suited action to thought and, in 1887, when but 16 years of age, "C. F." landed a job on the engineering corps of the Lehigh & Wilkes-Barre Coal Co., at Audenried, Penn. That was just 25 years ago, and today Mr. Huber is vice-president and general manager of this same company, without having once left its employ. Not much rolling there, do you think?

The advance from backsight to mine manager was mighty gradual, and even a high-powered telescope wouldn't reveal in the career of "Charles F." any attached object bearing semblance to favoritism or pull. The motive power back of his rise was "dreary drudgery," and the fuel burned was "persistent application."

At twenty, Mr. Huber was made division engineer for his company, taking charge of the Honey Brook collieries. Seven years later (1878), he came to Wilkes-Barre as chief engineer, serving under W. J. Richards, who was then general superintendent. In 1903, when Mr. Richards switched over to the Reading company, "Charles F." succeeded him, and was still further honored in 1909, when the L. & W.-B. people appointed him vice-president and general manager of all their operations.

Mr. Huber is quick to grasp details, and there is no faltering after his decision is made. Alert, keen, with every tingling nerve right on the job, his administration has been remarkably successful, one of the chief features being the unusually low accident rate in his mines.

Right here let me disgress long enough to say that "C. F." has considerable latent ability as a political reformer. This was clearly evident when he turned his attention momentarily from mining to the exposure of a rather extended system of graft on the part of township and borough officials in the districts where his mining interests were located.



CHARLES F. HUBER

The chief requisite for the making of a successful coal-mine manager is ability to scan a broad horizon. The fellow who starts as an engineer and who believes he can never see except when looking through a transit, will eventually cause his belief to become a positive reality. Charles Huber knows underground mining and is intimately acquainted with the methods employed at all his collieries, but he can follow the course of the coal through the stages of preparation with equal understanding, and it is really in the breaker where his genius has been most apparent.

During the past decade, the greatest advance in anthracite practice has occurred in screening, cleaning and general preparation of coal. The percentage recovery, if I may borrow a metal miner's phrase, is far greater today than it was a few years ago. Culm banks filled with commercial coal are now either monuments of past waste or present ignorance.

When I asked Mr. Huber whether the next few years would witness a still further advance in breaker practice, his answer showed plainly his belief that we have pretty well tied up the loose ends and corrected the most glaring leaks. He said, "Soon we may build another breaker, and when we do, I am quite sure it will be planned along the lines of our recent Stanton plant. Here we have embodied about all we know concerning coal preparation, and I anticipate no further radical changes."

While on the subject of breakers, I naturally inquired concerning the use of concrete, as compared with steel and wood as a material of construction, and I found "C. F.'s" views on the subject quite definite. He stated, "The great trouble with steel is its inflexibility, or rather the difficulty that necessarily follows an attempt to make any considerable alteration in the arrangement of the breaker building. Because of the frequent changes in the nature of the coal at a mine where sometimes as many as nine seams are worked, we often are compelled to cut away here and there and rebuild on somewhat new lines; I am quite certain that by having a concrete substructure and bins, with timber framing above, a condition is created that will lend itself readily to whatever changes become necessary."

Answering my query about the action of acid mine waters on concrete, he replied that he believed his company had pretty well overcome this trouble at Stanton. In this new breaker, the concrete floors of the bin were treated with one coat of pigment cement filler; then a coat of No. 1375 R. I. W., and finally another coat of No. 110 R. I. W. The guarantees on this were that R. I. W. would be heatproof, coldproof, acid- and waterproof. On top of this, was placed a hardwood lining or floor. Up to the present time, there has been absolutely no absorption of water by the concrete, and Mr. Huber believes the plan adopted will remedy the serious troubles that have resulted from sulphuric acid in mine water.

I doubt if any collieries in the entire anthracite field present a more cleanly or orderly appearance than the mines of the Lehigh & Wilkes-Barre Coal Co. When I suggested to Mr. Huber that I believed his chief hobby was "cleanliness about his plants," he smiled and replied: "One of the first ideas in relation to coal I ever conceived, was that it did not necessarily follow because coal was black and in the nature of things, dirty, we should readily concede that a coal plant must be an exhibition of dirt and disorder."

Mr. Huber agrees with Carl Scholz, of Chicago, that reversible fans are an unnecessary danger. In the matter of sealing off a mine fire, he advocates closing the intake side first, and states that in following this plan he has always been successful and never had an explosion as a result.

COAL AGE

Diplomacy

Perhaps the strongest diplomats are those who have an engaging way of expressing facts. Judged by appearances, the coal-miners' leaders have no clear understanding of the art of diplomacy. Every time a rise in wages is sought, they start to vilify the operator and try to make the man on the street bring pressure to bear on him. Already the papers are helping matters along by publishing trenchant editorials.

But what are the facts? The consumer seems convinced that the miner should have more money. He won't buy a paper which does not accord with that idea. He likes the editorials which advocate the interests of the worker, and he believes the latter has right on his side.

If the average layman only had a broader and better understanding of the situation, he would soon discover that he is the man principally interested. Eventually *he* pays the miner. We cannot see that the operator has overmuch to do with wages, so why should he take up the cudgels for the consumer who does not desire protection? Rather, let the operator rejoice that his men are doing well and better every year. He is thereby pleasing the miner and the consumer is also glad.

It is true that the bituminous operator has real competition to face from nonunion fields, and a wage advance might make conditions hard. But even here it is fairly certain that a like increase will be secured in nonunion districts.

In the anthracite region, however, with the restricted opportunity to increase output, the operators are relatively in a strong position and are more certain to retain their trade regardless of the price of coal. If competition in steam sizes troubles the hard-coal owners, they can save themselves by raising the price on their domestic output. Let the consumer pay the raise in wages; he has been clamoring to do so. Why deny him this privilege?

We would advise that the coal operator and coal miner meet as friends and connive to make an unthinking philanthropic public pay for the junket. That is diplomacy and diplomacy is peace.

The Coal Market

With the coal production of the country now seriously crippled, the condition of the fuel market becomes one of the predominating features in the industry. Until the trade is again in a normal state, COAL AGE will devote an additional page to the trade review department, in order to cover this branch in greater detail.

The market is essentially a strike market, and has been such for a number of weeks. The general trend of prices has been strongly upward for the past month, but has been accompanied by violent fluctuations, due to the varying reports from the labor conferences. These fluctuations have been so rapid and spectacular at times that the trade appeared to be almost on the verge of a panic.

Present interest is centered on the storage supplies, as any heavy, forced, buying movement at this time will undoubtedly precipitate a runaway market. No direct estimate of available supplies can be compiled for the reason that these are confined almost entirely to the bins of the consumer, and the retailer who has bought heavily in a number of instances for speculative purposes. Indirectly, most of the evidence seems to point to a substantial surplus.

That the railroad movement has been exceptionally heavy is evidenced by the report of the American Railway Association, which shows the gross surplus of idle cars, Mar. 13, to be the smallest in years. The Norfolk & Western Railroad handled a half-million more tons of coal during the first two months of the present year than in the same period last year, while the statement of net earnings of the Philadelphia & Reading Coal & Iron Co. for the month of January shows an increase of 17 per cent. It is also a fact that the anthracite shipments

for February exceeded those for the same month last year by over 800,000 tons; the awards to the anthracite miners for February amounted to 7 per cent. above the standard, the average being about 4½ per cent.

On the other hand, it is pointed out that the shortage of over 25 million tons in the foreign markets will cause a drain on our supplies. Also, that the anthracite consumption in January was 50 per cent. above normal while the surplus of 3 million tons usually on hand at the head of the lakes at this time, has been exhausted.

It will be shown later that American operators have profited considerable in the way of export business because of the strike in Great Britain. We have all heard about the futility of carrying coal to Newcastle, and most of us hardly believed that it would ever come to pass. The South American trade should be ours, and will be if we show an average order of intelligence in handling the matter.

Our Index of Coal Literature

With this number of Coal Age we present for the first time our index of coal literature, which henceforth will appear in the first issue of each month. This list will cover in its scope, all books and articles of technical merit published throughout the world, which pertain to the coal and coke industries in their various phases and developments.

It is a noticeable fact that each separate region where coal is mined is somewhat prone to regard itself with a certain degree of self-sufficiency, and is consequently inclined to perpetuate its own methods and practices. In this connection it should be recalled that the coal industry is well-nigh universal in extent, and no one of its fields is either so alien or so remote that it may not have a practical bearing on the needs of any other district.

While the United States has outstripped all other nations in the quantity of its coal production, the mere size of this enterprise, reared as it is so largely on the abundance of our natural resources, is scarcely to be taken as evidence of the excellence of our methods; and although the coal-mining industry in this country is probably as advanced and efficient as in any other, it should be recalled that the mines of England, for instance, have already tried and discarded many of our newest schemes, and that Germany, spurred on by the exigencies of economic conditions, is constantly bringing forth developments by which we will do well to profit.

Even within the boundaries of our own country, there is a considerable lack of comprehension between the various fields and the several districts of one field. Too often, we are apt to regard conditions as peculiar to a certain region when in reality they are only a phase of a problem which is common to many. One man here labors over a difficulty which someone elsewhere has already successfully solved.

It is the mission of industrial papers, technical books and the published proceedings of our engineering and learned societies, to bring the experience of the whole industry to a focus for the benefit of the individual reader. However, these means of collecting and disseminating knowledge necessarily have their limits, and the average man has neither the time nor inclination to wade through a great deal that does not interest him in search of that which will meet his particular needs.

More often than not, the requirements of the busy man arise on the instant and at once demand all the information it is possible to gather on a certain subject. If, through the aid of an adequate index, he has previously collected such publications as have appealed to him from time to time as possible necessities, then this required fund of information is at once available.

It is scarcely necessary to emphasize the value of such a list as Coal Age now offers to its readers. In carrying on this work we are fortunate in having effected an exclusive arrangement whereby we have the collaboration of the International Institute of Technical Bibliography. The journal of this Institute, which is not a commercial venture, is published monthly in seven sections, dealing with various branches of science and presenting abstracts which cover the entire field of engineering and technical industry. Our lists will embody such portions of these abstracts as are of special interest to our readers and the coal industry in general, together with certain additions of our own and a supervision that we are in a particularly advantageous position to give. We present this new feature with considerable confidence that it will prove of real value and will meet with general appreciation.

Social Revision

These are the days in which history is made in a hurry; opinions are being revised and changes of viewpoint take place with lightning rapidity. The sentiment of the dreamer of today becomes the accepted practice of tomorrow. A few years ago the "minimum wage" without trimmings would have served in England all the purposes of an amusing joke. Today even the London *Times*, despite its conservatism, is advocating that obnoxious socialist provision and the Premier is even urging its acceptance on the national parliament.

We are drifting faster and faster toward socialistic conditions. This would not be so deplorable if the desires of the people were not so steadfastly set in the direction of *political* as opposed to moral regeneration. As a matter of fact, socialism of any kind, whether of Marx, Lassalle or Bellamy, whether radical or Fabian, needs real socialists for success just as much as republicanism needs real republicans. It is not likely to be successfully inaugurated among people whose aims are entirely non-social and self-centered.

If everyone in a socialistic commonwealth seeks release from toil, restricted hours of work, excessive comfort, freedom from industrial restraint and such a profit from the use of the world's goods as conditions will not permit, then the provisions which the individual is seeking so diligently will only make for his impoverishment.

We have noticed that the growth of a sense of social obligation has failed to keep step with the growth of socialism. The many idle corner loafers of our cities and large towns, the needless number of men occupied at other work than industrial production, no less than the extension of the long ranks of our gilded youth, show that the burdens of a socialistic life are to be shifted, mose infelicitously, onto the backs of shirkers, whose dream is ever of rest and not of labor.

The new social doctrines will find their fitting environment only among those who understand that labor and bread are two inseparable entities. A few exceptions to that rule may challenge its truth, but the communities at large are fast bound to recognize its validity.

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Reducing Ventilation when Firing

The question raised by U. S. Wilson and Nelson Rigsby, "Should Ventilation Be Reduced Before Firing Shots,'" COAL AGE, March 9, page 718, is, in my opinion, a very important question and should interest all mining men.

The advocates of "slowing down the fan" before or during the firing of shots in a mine, contend that while the fan is running at its usual speed a large volume of air is carried into the mine. This current of air not only aids combustion but carries in suspension more or less fine coal dust, which intensifies what might otherwise be a local and harmless explosion. They point out several instances where explosions have occurred when shots have been fired where the air current was particularly brisk. As a prevention of such occurrences they advise "slowing down the fan" and thereby reducing the air current.

The question may properly be asked: Does not the trouble from gas or dust explosion arise more frequently from the excessive use of powder in blasting, rather than from an excessive quantity of air in circulation? There is not the slightest doubt, in my mind, but that it is a dangerous practice to employ such enormous quantities of powder as are commonly used in the preparation of shots in the average coal mine and especially where the air current is strong. But, on the other hand, is it a safe expedient to adopt, at all times and under all conditions, to slow down the fan when firing? It may be that in trying to escape one danger we are running into another even greater danger.

Almost every mine generates marsh gas in greater or less quantity. In some mines, it takes every available cubic foot of air to carry off the gases generated and to keep the mine in a safe condition. To reduce the air current before firing in such mines would create a condition that does not require the aid of a blown-out shot to cause an explosion. The application of a small open light is sufficient to fire the gas that would accumulate while the circulation of air is reduced.

To illustrate this point I beg to borrow a little example that appeared in COAL AGE, January 6th, page 430, in a communication by A. T. Wade, entitled "Danger In Gassy Mines." In this case a current of 50,000 cu.ft. of air is passing per minute. The safety lamp shows one-half of 1 per cent. of gas, in the return air current; and the quantity of gas given off in the mine is therefore

$0.005 \times 50{,}000 = 250$ cu.ft. per min.

It is shown that if this air current is reduced to 3000 cu.ft. per min. the percentage of gas will then be $\frac{250}{3000} \times 100 = 8\frac{1}{3}$ per cent. Under certain conditions of shooting down coal and exposing fresh feeders of gas, this percentage might be even greater.

A little study of the matter has convinced me that, as long as we use so much powder in blasting coal, just so long will shots and explosions occur, irrespective of whether the fan is slowed down or kept running at its normal speed. It is only when we decide to adopt a different method of working, such as longwall where it is possible; and eliminate, as far as practicable, the use of powder; or reduce the amount employed to a minimum, that gas and coal dust explosions in mines will cease.

PAT HOGAN.

Canton, Ill.

Stone Dust Pioneers

Referring to the communication of A. B Jessup contained in the issue of Mar. 9, permit me to point out that J. Taffanel was not the first to form the opinion that stone dust might be of use in mitigating the violence of an explosion. It is only just that J. W. Garforth's work in this direction should be given recognition. When giving evidence before a British commission in 1891 he advocated the use of stone dust. This was nearly 20 years before the results of the Liéven experiments were published. The Atkinsons in a book published a quarter of a century ago, suggested the same means of immunizing the coal dust in the mine.

I am not a strong advocate of either barriers or zones, as a means of preventing the propagation of a coal-dust explosion because the proper aim should be not to stop such an action after it has started, but to prevent it from ever getting a start. And with this end in view, every part of a mine should constitute a stone-dust zone.

Now that stone dust appears to be coming into its own, the question may arise as to where the method was first adopted in the United States. I may say that the Victor American Fuel Co., Colo., commenced to treat their mines extensively with stone dust or rather adobe dust in March, 1911.

SAMUEL DEAN.

Delagua, Colo.

Method of Working Coal Seam

In regard to the best method of working a coal seam of the character and thickness described by Charter Subscriber, Lexington, Ky., in COAL AGE, March 2, page 686, I would recommend the following system:

Assuming that the underlying stratum forming the floor of the seam is such as can be lifted without afterward causing trouble from the swelling and heaving of the bottom, as is the case with some fireclay floors when once disturbed, I would take up from 18 to 20 inches of the bottom to gain sufficient headroom on the main entry and other haulways. Assuming the top bench of coal, 14 inches thick, to be sufficiently strong and tenaceous to make a good roof, I would leave up this top coal in all rooms and entries. The parallel entry or air course and all crosscuts and rooms should be driven in the coal under the 14-in. top bench; it will not be necessary to lift bottom in driving any of these openings.

I would turn the rooms narrow, 8 ft. wide, for a distance of 15 ft. and then gradually widen out to a width decided upon and which would be governed by existing conditions, which under a cover of 100 ft. would be, say 30 ft. wide, with 15-ft. pillars between adjacent rooms. As the rooms reach the limit or boundary I would start the work of drawing back the pillars, at the same time dropping the top coal. It is important to keep the line of pillar work at an angle that would correspond to the line of fracture of the overlying stratum or roof of the seam.

I have seen this system worked very successfully in a seam of this kind but under a thicker cover. As will be noted by all practical men this system will reduce timbering to a minimum and at the same time reduce the possibility of accidents from falls of roofs which is the cause of the largest percentage of accidents in mining. Keeping up the top or roof coal until the work of pillar drawing is commenced will also give cleaner coal than can be secured by the

adoption of any other system, because the exposed fireclay above this coal weathers easily and drops into the coal both at the face and in transit.

J. W. Powell,
Mine Superintendent.
Coalmont, B. C., Canada.

Ice in Shaft

Replying to the inquiry of Thomas H. Devlin, superintendent, asking for suggestion as to best method of preventing the formation of ice in a wet shaft, in winter, Coal Age, Mar. 2, page 688, would say that if the matter of expense is not a presing consideration, I would consider the most practical plan to prevent the freezing of a downcast shaft in winter is as follows:

Select a place at the side of the shaft and make a dumb drift; or, better still, excavate a place 10 ft. wide and 20 ft. in length between walls. The walls can be made of stone, brick or concrete, the last being preferable. The foundation of the walls should be 12 ft. deep, but the headrom of the finished work need only be 6 ft. high. Roof this place with 40-lb. steel rails, with good fireclay bricks cemented between the rails, as when building an overcast, to make it air-tight.

Cover this with 12 in. of concrete to make the roof absolutely waterproof and fill in making the surface level. Put in a cement floor about 6 in. deep, laying a tile drain if necessary to provide for good drainage. Provide an opening and steps leading down into the cellar. Close this opening with sliding or hinged doors at the bottom of the steps, so as to regulate the quantity of air passing into the shaft through the cellar. Leave an opening in the walls next to the shaft, say from 4 to 6 ft. square, protected by 1-in. iron bars. This opening can also be provided with iron shutters for use in case of emergency, if desired.

This cellar is the hot-air chamber and is perfectly safe for attendants, being fireproof and waterproof. Place in this chamber as many steam radiators as may be necessary to heat the volume of air pasing through the chamber and down the shaft. These radiators should be so arranged as to heat the air to the best advantage. If desired, a portable boiler can be placed in this chamber, to be used for generating steam for use in pumping or other purposes. In this case, a hole should be left in the roof for the smokestack of the boiler.

As a further safeguard, the top of the shaft can be provided, if desired, with cheap iron shutters, which can be closed at night to cut off the cold downward current of air and prevent freezing. This plan will not require any reversing of the fan or changing of the direction of the air current, or the use of any double doors or overcasts other than those used in the present system of ventilation.

If desired, a further safeguard can be provided by placing water rings around the shaft, at different intervals, and arranging these rings so that hot salt water can be run from the surface into them and drained down the sides of the shaft. For this purpose, a common oil barrel can be used, provided with an exhaust steam pipe to heat the water, salt being added to the barrel, from time to time, as required. A pipe will be needed to conduct the water from the barrel to the water rings in the shaft. By this means very wet shafts can be kept comparatively free from ice in the coldest weather.

Republic, Ala.

Carbon Dioxide vs. Carbon Monoxide

Referring to Coal Age inquiry, page 688, Mar. 2, I desire to indorse the answer given to "Two Subscribers," Dayton, Tenn., in regard to the difference between carbon dioxide and carbon monoxide, with respect to the extinction of the flame of a lamp.

The oxygen in carbon dioxide does not exist in a free state as it does in the atmosphere, but is chemically combined with the carbon. This is true also of carbon monoxide; the oxygen it contains is combined chemically with the carbon. Carbon dioxide (CO_2), however, contains all of the oxygen with which carbon is capable of combining; but carbon monoxide (CO) can take up more oxygen, under certain conditions. On this account these two gases act very differently on the flame of a lamp. Carbon dioxide does not support combustion and extinguishes a lamp flame, this gas being incombustible. Carbon monoxide, on the other hand, is combustible; and when a light is introduced into the gas, if air is present, the CO burns, forming CO_2; in other words, the gas takes up more oxygen. It burns with a pale blue flame.

James Northover.
Seanor, Penn.

Reducing Ventilation When Firing

Referring to the discussion of the question, "Should Ventilation Be Reduced Before Firing Shots," p. 718, Coal Age, Mar. 9, I desire to say, this might work in some mines with safety; perhaps in the coal regions employing pick work, and where all the shots are fired between shifts when, in most cases, all the men are out of the mine except the shotfirers. In the anthracite region, however, shots are fired at any time during the shifts when the miner is ready. The anthracite mining law, Article 12, Rule 11, forbids the firing of any shots in a mine where locked safety lamps are used, except by permission from the mine foreman or his assistant; and requires the person in charge to examine the place and the adjoining places and satisfy himself that it is safe to fire the blast before permission is given. For this reason, the ventilating current could not be reduced before firing the shot, in anthracite mines.

There is another reason for not reducing the ventilation before firing, in such mines. In the anthracite region, the rooms are high and wide, generally, and the whole quantity of air is required to keep the place clear from gas. It would not be safe under these conditions to reduce the ventilation, if this could be done otherwise. I have worked in mines where they stopped the fan for 20 min., and the places were in the same condition after that time as before.

It would be inconsistent for me to advise slowing down the fan, or reducing the ventilation at the time of firing, knowing as I do the different methods of working here and in the "old country," where the means employed are more economical and greater safety is attained, and where firedamp is not passing from one working place to another, but is conducted directly into the return current.

George Knight,
Fireboss.
Plainville, Penn.

Ice in Shaft

Referring to Thomas H. Devlin's question relating to the accumulation of ice in wet downcast shafts, Coal Age, March 2, page 688, it seems to me that the appended note to this question does not help the solution of the problem; except by the suggestion that suitable water rings might be installed at different levels in the shaft to collect the water and render the shaft drier; and by the use of steam pipes in the shaft. I have pleasure in asking Mr. Devlin to try keeping one or two coke fires going at the top of the intake shaft and about two or three yards from the same. I have seen this remedy tried and it was very successful. The shaft was brick lined having buntons two fathoms (6 ft.) apart that carried the wooden cage guides and furnished the necessary support for the pumping apparatus, pipes, signal wires, etc.

The cages were fitted with shoes, which, in the writer's opinion, were a greater source of trouble than rope guides would have been under the same circumstances. In this shaft, however, the trouble from the accumulation of ice only occurs in the severest weather.

Matthew Stafford.
South Wellington, B. C., Canada.

All Questions Must be Accompanied by Name and Address—Not for Publication

Duties of Fireboss Required by Anthracite Mine Law

In reading the anthracite mine law I find that it specifies in a number of places the duties of the mine foreman and his assistants, but makes very few references to the duties of the fireboss. Article 12, Rule 3, gives the mine foreman full charge of all matters pertaining to the ventilation of the mine. Rule 4 makes it the duty of the mine foremen, or his assistant, to examine all accessible parts of the abandoned portions of the mine in which explosive gases have been found, etc. Only in one place do I find a direct reference to the duties of the fireboss. This occurs in Rule 7 of Article 12, which states, "It shall be the duty of the fireboss to remain at the danger station until relieved by some person authorized by himself or the mine foreman, etc."

Can you tell me what duties belong to a fireboss under the anthracite mine law, and do coal companies have to employ a fireboss for such duties? Also, are firebosses required to have a certificate the same as mine foremen and assistant mine foremen? P. H. MAGINNIS.

Shamokin, Penn.

There are two distinct references to the fireboss in the anthracite mine law. These occur in Article 8, Section 9; and Article 12, Rule 7. The former reference is as follows:

Section 9. And no person shall be permitted to act as fireboss in any coal mine or colliery, unless he has had five years' practical experience in mines as a miner, three of which he shall have had as a miner in mines wherein noxious and explosive gases are evolved, and the said fireboss shall certify to the same before entering upon his duties before an alderman, justice of the peace, or other person authorized to administer oaths, and a copy of said deposition shall be filed with the district inspector of mines wherein said person is employed.

The second reference is as follows:

Rule 7. A station or stations shall be established at the entrance to each mine or different parts of each mine, as the case may require, and a workman shall not pass beyond any such station until the mine or part of the mine beyond the same has been inspected and reported to be safe. It shall be the duty of the fireboss to remain at the danger station until relieved by some person authorized by himself or the mine foreman, who shall stand guard until said mine or part of mine shall be reported safe, and he shall not let any person pass without permission from the fireboss.

The present anthracite mine law certainly leaves a great deal to be assumed or understood in regard to the fireboss and his duties, in a mine generating explosive gases. Article 8 provides for the certification, by a duly appointed examining board, of the mine foreman, who must have had at least five years' practical experience as a miner and be of good conduct, capable, and sober. He must pass a satisfactory examination before the examining board and be certified by said board to the Secretary of Internal Affairs, who shall issue a certificate in due form bearing the seal of the State of Pennsylvania. The law makes no provision for the examination or certification of the fireboss, in this article, but clearly states (Section 9) that no person shall be permitted to act as fireboss in any coal mine, etc., as given above.

The usual work of the fireboss is the examination of the mine for gas by means of a safety lamp at least three hours before the time for the workmen to enter the mine, each day. By the anthracite law, Article 12, Rule 5, this work is made the duty of "The mine foreman or his assistant," no reference here being made to the fireboss. It is generally assumed in the anthracite region that the assistant foreman is the acting fireboss. According to Article 8, Section 9, no person shall be permitted to act as fireboss in any coal mine except he has had five years' practical experience in mines as a miner, three of which shall have been in mines generating noxious and explosive gases. It would seem that this requirement would prevent some mine foremen from acting as fireboss, because they have not had the required experience in mines generating explosive gases.

In the anthracite region the assistant mine foreman is the fireboss and must perform all the duties assigned to the assistant foreman in the law. The law requires (Article 12, Rule 1) the owner, operator, or superintendent of the mine or colliery to employ a competent person who shall be called mine foreman. The law also requires (Rule 2) that whenever a mine foreman cannot personally carry out the provisions of this act, he shall employ a sufficient number of competent persons to act as his assistants. Further than this, the law does not compel the employment of an assistant foreman or fireboss. The law forbids (Article 8, Section 1) any person to act as mine foreman or assistant mine foreman who is not registered as holding a certificate of qualification or service under the act.

Arrangement of Colliery Buildings

I would like to draw the attention of the readers of COAL AGE to a subject that we mining engineers in charge of construction work have long felt should receive more attention than it has in the past. It is the need of a more systematic grouping and arrangement of the buildings forming the surface plant, at a bituminous mine.

The demand is more and more urgent each year for increased economy in operation. Much attention has been given to the adoption of new methods and the installation of new and improved machinery for the handling of coal at the surface, its loading and shipment; but this very fact, the adoption and installation of methods and machinery not anticipated in the previous arrangement of the surface plant, has, in most cases, led to a most unsystematic arrangement of the buildings. As a consequence it is often necessary to transmit power long distances; to transport by inconvenient tracks and trams, parts of machinery needing repairs, or work undergoing construction; to say nothing of increased danger and annoyance caused by the multiplicity of tracks, live wires and other evils that might be avoided and should be eliminated in the design of a more up-to-date plant.

Can we not have a discussion of this subject by colliery engineers, superintendents and foremen, who have been up against the annoyances and delays growing out of a lack of arrangement? Give plans of proposed arrangements that will reduce time and cost of handling.

F. D. BUFFUM,
Mining Engineer.

Ellsworth, Penn.

Developing a Thick Vertical Coal Seam

I may soon have to take up the development of a vertical coal seam 16 ft. thick, 1000 ft. deep and one mile long. I would greatly appreciate having this question thoroughly discussed in COAL AGE. Many of the older readers must have had valuable experience in the development of such a seam of coal.

CHAS. M. SHERMAN.

Farmington, Ill.

[This is an interesting and important question, and we hope it will receive the attention it deserves.—EDITOR.]

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Interesting Questions

Calculations Required in Pumping

Ques.—What is the theoretical pressure, or the pressure ignoring friction, corresponding to a vertical head of 300 ft. of water?

Ans.—Ignoring friction, the pressure at the bottom of a column pipe in a shaft 300 ft. deep is the static pressure due to this head; or

$$p = 300 \times 0.434 = 130.2 \text{ lb. per sq.in.}$$

Ques.—When pumping 400 gal. of water per min. through a 5-in. discharge or column pipe, in a shaft 300 ft. deep, what is the friction head due to this flow; and what is the total head (h) and the pressure (p) at the pump, in action?

Ans.—The friction head, in feet, due to the flow of water in column pipe, in ordinary mining practice, is calculated thus,

$$h_f = \frac{0.01 \times 300 \times 400^2}{8 \times 5^5} = 19.2, \text{ say } 20 \text{ ft.}$$

The total head against the pump, in this case, is, then,

$$h = 300 + 20 = 320 \text{ ft.}$$

The pressure at the pump when pumping is

$$p = 320 \times 0.434 = 138.88 \text{ lb. per sq.in.}$$

Ques.—(a) Find the diameter of the water cylinder or plunger of a pump required to handle a flow of 250 gal. a min., in 10 hours each day, assuming a piston speed of 120 ft. per min. (b) Calculate the diameter of the suction and discharge pipes for this flow. (3) If the shaft is 480 ft. deep and the available steam pressure at the pump is 60 lb. per sq.in., what will be the required diameter of the steam cylinder for this work?

Ans.—(a) The pump must handle in 10 hours all the water the shaft makes in 24 hours; or

$$G = \frac{250 \times 24}{10} = 600 \text{ gal. a min.}$$

For a piston speed $S = 120$ ft. per min. the required diameter (d) of the water end of the pump is

$$d = 5.37\sqrt{\frac{600}{120}} = 5.37\sqrt{5} = 12 \text{ in.}$$

(b) Suction pipe,

$$d\ 0.35\sqrt{600} = 8.57, \text{ say } 8\tfrac{1}{2} \text{ in.}$$

Discharge pipe,

$$d = 0.25\sqrt{600} = 6.12, \text{ say } 6 \text{ in.}$$

(c) It is necessary, first to calculate the friction head caused by a flow of 600 gal. per min. through 480 ft. of 6-in. column pipe, and, say, 20 ft. of 8.5-in. suction pipe; thus,

$$h_f = \frac{0.01 \times 600^2}{8}\left(\frac{480}{6^5} + \frac{20}{8.5^5}\right) = \text{say } 28 \text{ ft.}$$

The total effective head on the pump is then $h = 480 + 28 = 508$ ft.

The diameter (D) of steam end, for an available steam pressure of 60 lb. at the pump, is then found thus,

$$\frac{D}{12} = 0.7\sqrt{\frac{508}{60}}$$

and

$$D = 0.7 \times 12\sqrt{\frac{508}{60}} = 24.4, \text{ say } 24 \text{ in.}$$

Ques.—What horsepower of engine will be required to pump 165 gal. of water per min. from a shaft 1200 ft. deep?

Ans.—The formula in common use for calculating the horsepower of a pump assumes an efficiency of 75 per cent. for the steam end. It is

$$H = 0.00034\ Gh$$

$$= 0.00034 \times 165 \times 1200 = 67.3 \text{ hp.}$$

Ventilation

Ques.—An airway 8x9 ft. is passing 45,000 cu.ft. of air per minute; what is the velocity of the air current?

Ans.—The sectional area of this airway is $8 \times 9 = 72$ sq.ft. The volume of air passing is then

$$v = \frac{q}{a} = \frac{45,000}{72} = 625 \text{ cu.ft. per min.}$$

Effect of Fall of Barometer on Percentage of Gas

Ques.—Assuming that the abandoned workings in a mine have a total volume of 1,000,000 cu.ft. and that the air in this space contains 10 per cent. of marsh gas, how would the air current on the entry skirting these old workings be affected if the barometer should fall suddenly from 29.55 in. to 28.74 in. in nine hours? Supposing that this air current is 10,000 cu.ft. per min. and carries normally 2 per cent. of gas, what would be the percentage of gas in the current during the barometric fall, and would this change be detected readily on the safety lamp?

Ans.—Assuming the temperature of the mine air remains constant, the volume of air contained in the abandoned workings will increase or expand in the inverse ratio of the fall of the barometer. In other words, the volume ratio is equal to the inverse barometric ratio. Thus, calling the expanded volume of the air in the abandoned workings x,

$$\frac{x}{1,000,000} = \frac{29.55}{28.74}$$

$$x = \frac{29.55 \times 1,000,000}{28.74} = 1,028,183 \text{ cu.ft.}$$

Now, subtracting the original volume of the air in the abandoned workings, the volume of air thrown out on the entries is 1,028,183 — 1,000,000 = 28,183 cu.ft. of air in nine hours, or, say, 52 cu.ft. per min.

Expanded volume of air in goaves	1,028,183 cu.ft.
Original volume of air in goaves	1,000,000 cu.ft.
Volume of air thrown out on entry	28,183 cu.ft.

Quantity of gas in air thrown out

$$\frac{28,183 \times 0.1}{9 \times 60} = 5.2 \text{ cu.ft. per min.}$$

Quantity of gas in air current before change

$$10,000 \times 0.02 = 200 \text{ cu.ft. per min.}$$

Total quantity of gas during fall of barometer

$$200 + 5.2 = 205.2 \text{ cu.ft. per min.}$$

Percentage of gas

$$\frac{205.2 \times 100}{10,000} = 2.052\%$$

It would not be possible to detect this slight increase in the percentage of gas in the air current by a safety lamp.

Causes of Mine Accidents

Ques.—What causes the greatest number of accidents in coal mines (explosions excepted) and what precaution should be taken to prevent them?

Ans.—The largest number of coal-mine accidents is caused by falls of roof and coal at the working face. The precautions to be taken to prevent these accidents or reduce their number are, a more thorough inspection of the working face to discover any slips or faults in the roof, or any loose slate or rock that should be taken down, and to ascertain where timber is needed to support the roof or coal. Miners should be instructed to inspect their own working faces and to set any necessary timbers before proceeding to load their coal. The failure to do this is the cause of many accidents. In some mines it is important to adopt a systematic method of timbering the faces of rooms. A plentiful supply of the proper size of mine timbers must be kept constantly on hand and all orders for timber be promptly filed.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

The apparently better news from the coal regions with reference to the chance of avoiding a long strike, has led to a decided increase in the disfavor with which propositions like the Lee bill are being viewed in Congress. Nothing has been heard thus far from the subcommittee, to which the Lee bill was sent, and so far as can be learned, nothing has been done by the Senate Interstate Commerce Committee with regard to the so called Townsend strike bill, which provides for the appointment of a commission by the President to investigate and report upon cases in which serious strikes occurred. The Townsend bill has proved distasteful to a good many members of the interstate commerce committee, and it is understood that a substitute for it will shortly be offered. In this, it will be sought to eliminate the features that have been most sharply objected to in the Townsend measure.

Attitude of Administration

Meanwhile, it is well understood that President Taft favors doing anything that the federal government legitimately can to prevent the threatened strike from becoming acute, although he is not disposed to strain the provisions of the law in order to attain that end. He has given full assurance of his interest in the situation and those who are closest to him are convinced that the problem will not be neglected in any degree whatever. It is expected that some report on the Lee bill will be made shortly, and that in this the Democrats will state the views of their party as an organization with respect to the question of federal intervention of this kind. The notion of federal interference with state activities is, of course, foreign to their principles, but they have in some instances been inclined to make an exception of so serious a matter as the coal situation has appeared likely to become.

Stonega Coal Co. Discrimination Case

The recent decision of the Interstate Commerce Commission in the case of the Stonega Coal & Coke Co. against the Louisville & Nashville R.R. presents a number of points that are of considerable interest and importance even outside the region which is immediately affected.

Some of the principal findings of the commission in this case are as follows:

A railroad company which holds itself out to the public as a common carrier, files tariffs with and makes reports to the Interstate Commerce Commission as required by law of common carriers, and engages in the transportation of interstate traffic, is a common carrier subject to the provisions of the act to regulate commerce. The character of service a railroad company renders, and holds itself out as willing to render, is the controlling inquiry in a proceeding to determine whether such company is a common carrier. The fact that a carrier maintains lower rates from points on its own line than rates in force on the same kind of traffic from nearby points on the line of another railway and not on its own line, does not of itself amount to undue discrimination against shippers at the latter points. The principal defendant renders a transportation service to owners of coal operations in the Black Mountain district of Virginia, on the line of the Virginia & Southwestern Railway, but refuses to render a like service, under substantially similar circumstances and conditions, to complainants' coal operations in the Appalachia district on the Interstate Railroad. It is, therefore, held that such conduct amounts to undue discrimination against complainants.

With reference to the question of rates, the commission expresses itself as of the opinion that there is an undue discrimination against the complainants, but that the reasonableness of the transportation charges, although investigated to some extent, is not directly involved in this case. Accordingly the Commission adds:

In the present state of the record, we are unable to determine what the rates should be in order to remove the discrimination. It may be that the defendants will be willing to establish a service to and from complainants' mines and plants, on the Interstate R.R., on the same basis as the service now in effect to and from the St. Charles mines, on the Virginia & Southwestern, and thereby remove the discrimination; and an opportunity will be given them to do so. Should they fail to reach a satisfactory adjustment, a further inquiry will be had by the Commission and such order made as may be found necessary and proper.

Alabama

Birmingham—There was some talk in this vicinity recently, to the effect that if a national strike of bituminous miners should be called, about 20,000 mine workers in the Birmingham district would respond by going out on strike. The miners here are only partially organized but it is reported that their sentiment is quite strongly in favor of backing up the demands of their fellow workers in the central states. J. R. Kenamer represented the local organization at the meeting of the miners' policy committee, in Cleveland, Mar. 25.

The controversy between Gov. O'Neal and the Sloss-Sheffield Coal & Iron Co., over the price paid for convicts is being watched with keen interest. It is believed that the company will decline to pay the requested increase for the convicts and that the controversy will eventually develop a most interesting situation. In the event of the Sloss company declining to pay the advance requested by the governor, it is believed that the entire convict supply of that company will be given to the Banner mines for service there.

Colorado

Oak Creek—E. E. Shumway, president and general manager of the Rocky Mountain Fuel Co., has purchased the property of the Junction City Coal Co., of Oak Creek. This consists of 160 acres of rich coal land on the main line of the Moffat road, four miles north of Oak Creek. The purchase price was $70,000. Mr. Shumway has given a 20-year lease on the Junction City property to W. C. Ferguson of the Empire Coal Mining Co., of Denver, who will immediately install a complete modern equipment for operation of the mine. He expects to have the property in shape for the extensive production of coal by next fall, and to employ about 200 men.

Illinois

Marissa—The tipple of the White Oak mine, belonging to the Egyptian Coal & Mining Co., of St. Louis, was seriously damaged, Mar. 26, when a portion of the structure gave way under the weight of a quantity of coal which had been piled up against it. A number of pit cars, containing the tools of miners who were leaving the workings, were buried in the débris.

Taylorville—The main shaft of the Peabody Coal Co.'s new mine at Kincaid has been sunk to a depth of 342 ft. and a 7½-ft. seam of coal has been disclosed at this level. The air shaft still lacks about 20 ft. of reaching the coal. Both shafts are being lined with concrete. When this work is completed, two more shafts, for a second mine, will be put down at a point about one mile distant. In connection with the large electric power plant which the coal company

proposes to build at Kincaid, an immense reservoir will be constructed. Water will be diverted to this from the South Fork of the Sangamon River, by means of a dam.

Collinsville—One man was crushed to death, another perhaps fatally injured and three others seriously hurt, Mar. 26, by falling slate and coal in Mines No. 2 and 3 of the Lumaghi Coal Co. Three of the men were injured by a fall of slate in Mine No. 2, while the other two were caught by separate falls of overhead coal in Mine No. 3.

Bloomington—Following an inspection trip over the Toluca & Rutland branch of the Chicago & Alton R.R., by officials of the Chicago, Milwaukee & St. Paul, it was announced that the latter road may purchase the branch road and extend it 60 miles south in order to reach the central Illinois coal field.

Indiana

Brazil—The Brazil Block Coal Co. has declared its intention to discontinue the operation of its mines after Mar. 31. This company practically made Brazil. It has opened and operated 45 mines in this vicinity and has been in operation for forty years. The company, which is practically identical with the Chicago & Eastern Illinois R.R., has a score of mines in Clay, Vermilion and Sullivan Counties. Recently, the railroad was leased to the Frisco system and this latter concern will now also lease the coal company's interests.

The German Coal Company's mine southeast of Brazil caved in Mar. 27, obstructing the mouth of the shaft and putting the cage out of commission. The miners all escaped through another shaft. The accident was costly, since the company was working hard to fill a large number of orders prior to the suspension which if it lasts ten days or more will force the factories in Brazil to close down.

Iowa

Davenport—C. M. Moderwell & Co. and the Sunnyside Coal Co. have each filed petitions against the Milwaukee railroad, alleging that the defendant company refused to accept certain cars of coal for shipment. Moderwell & Co. ask damages of $357 and the Sunnyside company a judgment of $396.

Kentucky

Whitesburg—It is reported here that an Eastern syndicate has bought 20,000 acres of coal and timber lands along the Kentucky River, Line Fork and Kings Creek in the southern part of Letcher County, at a price said to be the largest ever paid for mountain coal lands in this region. About two-thirds of the property lies along the new extension of the Lexington & Eastern R.R. It is said that development of the property will be started this year.

Lexington—A number of coal companies in the Big Sandy district recently had cause to complain of a serious lack of cars. They also declared that many cars which should have been sent into the Big Sandy section were taken into the Kanawha and New River fields. The companies affected by the shortage were: the Northeast Coal Co., the Pike Colliery Co., the Greno Coal & Coke Co., the Elkton Consolidation Coal & Coke Co., the Mitchell Coke Co., the Kewanee Coal Co., the W. K. Steel Coal Co., the Wagner Coal Co., the Little Creek Coal Co., and the Colonial Coal & Coke Co. The Interstate Commerce Commission promised that in so far as lay within its power, it would take steps to relieve the situation.

Louisville—The stockholders of the Louisville Property Co., a holding corporation of the Louisville & Nashville R.R. Co., have ratified the recent action of their directors in selling coal and timber land to Thomas Cairns, of Pineville, at $1,800,000, and Mr. Cairns states that the coal and timber property consists principally of holdings in the counties of Bell, Whitley and Knox, Kentucky, amounting to 46,000 acres, and containing the best coals, as a whole, in the southeastern Kentucky coal field. There are 12 large going coal operations already under lease. His intention is to sell in groups of from 3000 to 5000 acres.

Missouri

Bevier—All the coal mines in this district resumed operations on Apr. 3, by authority of an agreement between the operators and miners of the Southwest district, which provides that work will be continued for a period of 30 days, while a new scale is being negotiated.

Ohio

Steubenville—Fire broke out in the Robert Hill coal mine here, Mar. 23, and 12 men, who were in the mine, had a narrow escape from suffocation. A remarkable discovery was made, when it was found that apparently, a fire, which broke out in the same mine 12 years ago, had eaten its way through a mile of coal and slate. Experts are investigating the matter on the theory that the fire had been burning for 12 years and that the recent blaze came about when the last of the wall was consumed and the fire given access to the main shaft of the mine.

Cleveland—The joint conference of bituminous operators and miners, in session here, agreed on a compromise, Mar. 29, whereby all the original demands of the miners are withdrawn and the following increases in pay are to be granted: Five cents a ton for mining lump coal, 3c. for all other coal and 5.26 per cent. for men paid by the day. These terms still have to be submitted to a referendum vote of the miners and although no dissension is anticipated, it will take about two weeks to secure the necessary ratification. Meanwhile, a suspension is in effect throughout the organized bituminous fields, which will probably last from two to three weeks, pending an adjustment of the several wage contracts.

Cleveland—Owing to the extremely heavy ice in the upper lakes it is announced by the railroads that it will be May 15 before the season of lake navigation opens, instead of a month earlier as usual. In addition, it is said that the amount of coal remaining on the upper lake docks is the smallest ever known at this time of the year and the demand for coal will be unusually heavy.

Pomeroy—Some trouble was experienced recently by operators in this field on account of the high water which prevailed. A number of the mines were flooded and the production was somewhat curtailed.

Oklahoma

Muskogee—Affairs of the Sans Bois Coal Co., at McCurtain, in one of whose mines 74 miners lost their lives, Mar. 20, were placed in the hands of receivers recently by order of Judge Campbell in the United States District Court. The receivers were appointed on the petition of the Superior Savings & Trust Co., of Cleveland, Ohio, holders of a $250,000 mortgage, secured by the properties of the company at McCurtain. The banking company alleges that $55,000 in interest on the bonds is past due and that the company has other debts which it is unable to pay.

Pennsylvania

Bituminous

McKeesport—Three hundred coal miners returned to work, Mar. 27, in the Camden mines, after an enforced layoff of about two weeks. It is reported that water overflowing from the Monongahela River caused the mines to be closed down, and it was impossible to resume work until the river had receded.

Greensburg—The Lacolle Coal Mining Co. has awarded contracts for the construction of 7000 ft. of railroad, a steel tipple and an electric power plant, and expects to have a production of 300 tons of coal a day in the course of the next three or four months. It is announced that a contract has been made for the sale of the entire output of the mine, up to 1000 tons a day, for a term of five years. The Lacolle company owns 174

acres of ground and the coal under 1500 acres, located one and a half miles from Bolivar. Over 1000 ft. of headings have been driven, which show the thickness of the seam to be something over 6 feet.

Monongahela—Preparations are being made to sink a new shaft for the Catsburg mine, on the Sampson farm, near here. A large ventilating fan will be installed and other improvements made.

Johnstown—The Sunnyside Coal Co. expects to reopen the upper vein of the Sunnydale mine within a week or ten days and employ an additional 100 men, in order to supply the demand for coal. The plane is being extended from the lower vein, heavier rails being put down.

The Valley Smokeless Coal Co. has posted a notice to its employees, which states that, beginning Apr. 1, an advance of 10 per cent. on present prices will be paid as long as existing market conditions continue. When the market fails, the company agrees to pay the same scale of prices as then obtains at other mines along the Somerset and Cambria division of the Baltimore & Ohio R.R.

Rumors to the effect that the Berwind-White and Merchants' Coal companies would grant a raise in wages in the Windber and Boswell fields have been officially denied.

Uniontown—The H. C. Frick Coke Co., on Mar. 30, announced a general advance in wages, effective Apr. 1. The present scale is the highest ever paid in the region, amounting as it does to $1.44 per 100 bu. The advance on room and rib coal is 6⅔ per cent., on heading coal, 5⅓ per cent., and other advances range from 5¼ to 10 per cent.

Ebensburg—S. L. Reed and Webster Griffith have about finished securing options on 8000 acres of coal land in this vicinity. The price offered is $110 an acre, and the options expire June 1. It is not known who the intending purchasers are, but the Ebensburg, Lackawanna and Cardiff companies have all been mentioned in this connection. About 5000 acres of the tract lie along the Cambria & Indiana R.R. in the Blacklick Basin and 3000 acres lie near Vetera and Colver. The land adjoins the properties of the Vinton Colliery Co. and the Commercial Coal Mining Co. Shipping facilities are good, as in addition to the Cambria & Indiana R.R. the New York Central also taps the field.

Anthracite

Scranton—The People's Coal Co., owner of the Oxford colliery, in West Scranton, has offered a bonus of 10 per cent. to its mine workers if they will remain at work during any suspension that may take place in the anthracite region, and also the right to participate in any victory that may be won by the striking miners. This is similar to the course taken by the Pine Hill Coal Co. The Oxford mine, employing 300 men, was the only large anthracite colliery that worked steadily during the 1902 strike, when its whole output was sold at a premium, prices of $25 a ton being secured in some instances.

Underground settlings in the workings of the Capouse colliery of the Scranton Coal Co. threaten to wreck the big plant of the Graff Furnace Co., in the Keyser Valley section of West Scranton. Property damage to the extent of $12,000 was done, Mar. 25. Eight buildings, on ground embracing an entire city block, were so seriously affected that the company was unable to resume operations.

Shenandoah—The Madeira Hill Co., of Philadelphia, operating in this city, has struck the Buck Mountain vein, at its West Bear Ridge workings at Mahanoy City Plane. The vein shows a thickness of 10 ft. This adds new life to the Stanton colliery and means much for the Gilberton Valley.

Pottsville—Forty timbermen at the Hammond colliery of the Philadelphia & Reading Coal & Iron Co. went on a strike recently because the officials endeavored to compel them to use safety lamps without giving them any additional pay. The miners claimed they were entitled to extra compensation when forced to use this style of lamp.

Tamaqua—Because a number of men at work in the Lehigh Coal & Navigation Co.'s mines near here, refused to wear union buttons, nearly 1000 union miners quit work, Mar. 26. Officers of the coal company declared that unless the men returned to work all the collieries of the company, employing 9000 men, would be closed down.

Wilkes-Barre—Mayor Kosek, of this city, in an effort to avert a strike, recently issued an invitation to the executive heads of the cities and boroughs in the anthracite region to meet and formulate a plan whereby a strike or suspension might be avoided. This meeting was held, Mar. 28, and an appeal for intervention was sent to President Taft.

West Virginia

Bluefield—A powder explosion in the mines of the Thomas Coal Co. at McComas, near here, resulted in the injury of eight men, four of them seriously but none fatally. The men were entering the mine carrying cans of powder when a torch set fire to a bag in which the cans were carried.

Morgantown—A 20-year contract has just been closed by the Elkins Coal & Coke Co., of Morgantown, with the Lehigh Coke Co., involving 9,000,000 tons of coal, to be supplied at the rate of 1200 to 1500 tons a day, for the by-product coke ovens of the Lehigh company at South Bethlehem, Penn. Another contract just closed by the Elkins company, involves 96,000 tons of coal to be delivered to the Lackawanna Steel Co. To fill these and other contracts, a new mine will be opened in addition to the two mines already in operation in the Bretz field, on Deckers' Creek. The company is advertising in local papers for 600 workmen. Plans for the new mine have been prepared, and work on the shaft will be started early in April.

Fairmont—An announcement of vital importance to West Virginia operators was made recently by the Baltimore & Ohio R.R., to the effect that its rate on coal from the Fairmont regions to the Great Lakes would be reduced from 96¾c. to 90c. This action was the result of the further reduction of the rate from the Pittsburg field to the lakes from 88c. to 78c., thus giving the shippers in the last-named district an advantage over companies operating in the Fairmont district of West Virginia. Heretofore the Pittsburg district has enjoyed a differential of over 8c. and cutting this rate an additional 10c. was not to the liking of the West Virginia people.

Virginia

Wise—The Interstate Commerce Commission decided, Mar. 25, that through routes and joint rates for the transportation of coal and coke from mines in Wise and Lee Counties, Va., to destinations in Ohio, Kentucky and other states, must be established by the carriers operating from those mines. While no definite order was made by the commission, the case brought by the Stonega Coke and Coal Co. and others, will be held open to await for a reasonable time the voluntary action of the carriers.

Washington

Seattle—The Issaquah coal mine, a commercial landmark of the Northwest, has passed into the hands of a German syndicate for a consideration of approximately $200,000. One-half million dollars will be invested at once in improvements. The mine is owned by the Seattle, Lake Shore & Eastern and has been closed for 15 years. The name of the new company will be the Issaquah & Superior Coal Co. Before the investment was made the mines were fully explored.

Spokane—It is reported that $12,000,000 will be expended by the Northern Anthracite Syndicaate, in eastern Canada, in developing 12,800 acres of coal lands in the Groundhog Mountain district of British Columbia, 150 miles north of Hazleton. This work, which will occupy three years, includes the building of a railroad from the forks of the Skeena and Stikine Rivers to the mouth of the Nass River and Nasoga Gulf, also bunkers at points on the Pacific coast.

Personals

John Ridgney, Jr., has been appointed division engineer of Pratt No. 2 division, Tennessee Coal, Iron & R.R. Co.'s coal mines, to succeed George W. Postell, resigned.

J. J. Marshall, formerly chief engineer of the Loup Creek Collieries Co., is now in charge of extensive development work for the Gauley Mountain Coal Co., Ansted, W. Va.

Robert Fairbain, of Streator, Ill., has purchased the property of the Star Coal Co. at Galesburg and will take charge of its operations. Charles Rathbun is thus relieved of his connection with the company, which is in accordance with his desires for several years past.

A. R. Brown, who is in charge of the West End rescue station of the Bureau of Mines at Birmingham, Ala., recently made a tour of the larger coal-mining camps in the vicinity for the purpose of organizing and training rescue and first-aid corps among the miners.

Charles T. Harther, manager of the Powhatan Coal Co., of Toledo, has been made president and treasurer of the newly organized Central State Coal Co. of that city. Mr. Harther was formerly connected with the Johnson Coal Mining Co., the New York Coal Co. and the Lorain Coal & Dock Co. in Columbus.

F. R. Wadleigh, fuel engineer and assistant general manager of the Chesapeake & Ohio Coal & Coke Co., attended the recent meeting, in New York, of the American Society for Testing Materials. Mr. Wadleigh is a member of the coal specifications committee of the society. He had just returned from Cincinnati where he testified in the famous McKell case against the Chesapeake & Ohio.

A party of Colorado School of Mines students, with Professor Allen in charge, recently spent several days inspecting the Trinidad coal field. The itinerary was arranged by James S. Thompson, division engineer for the Colorado Fuel & Iron Co., and was most interesting and instructive to the students. F. P. Bayles, of the Cokedale mine, and William McDermitt, division engineer for the Victor-American Fuel Co., guided the boys through the properties under their charge.

Frank A. Prendergast, for the past ten years general manager of the Baltimore & Ohio Coal Co., of Columbus, has retired in favor of F. B. Lockhart, formerly connected with the United Coal Co., of Pittsburg. Mr. Prendergast has been anxious to be relieved of his official duties for some time. He will, however, continue to give some attention to the affairs of the company. Mr. Lockhart, the new president, is an experienced coal man and will continue the previous policies of the company.

Obituary

Wade Hampton Echard, aged 26, one of the prominent younger business men of Fayette County, Penn., died at his home in Uniontown, Mar. 11. He was educated at the Iron City Business College, Pittsburg; Grove City College, Grove City, Penn., and West Virginia University, Morgantown, W. Va. Mr. Echard was president of the Unity Coke Co., the Northern Coke Co., the Peerless Coke Co., and the Franklin Coke Co., all of Connellsville, Penn.

Construction News

East Liverpool, Ohio—The West Point Coal Co. will establish large coal-storage yards at this point. J. L. Francis is general manager.

Monongahela, Penn.—A new shaft will be put down and ventilating equipment installed in connection with the Catsburg mine near here.

Lonaconing, Md.—It is reported that the Maryland Coal Co. will expend $200,000 in extending its mining developments in this vicinity.

Morgantown, W. Va.—Plans have been prepared by the Elkins Coal & Coke Co. for opening a new mine in the Bretz field on Deckers Creek. Work on sinking the shaft will be started early this month.

Duluth, Minn.—It is reported here that C. J. Farrar, acting for the Pittsburg Coal Co., has purchased property at Ashland, Wis., on which the company will build and equip a large coal dock, at an expense of $250,000.

Pittsburg, Penn.—The Lily Coal & Coke Co. has prepared plans for a new operation at West Brownsville, to have a daily capacity of 3000 tons. The plant is to be electrically equipped, and will cost about $300,000.

Wheeling, W. Va.—The McAlpin Coal Co., operating in Raleigh County, has increased its capital from $100,000 to $200,000, and is planning extensive development of its property. John Laing is president of the company.

Bolivar, Penn.—The Lacolle Coal Mining Co. has awarded contracts for the construction of 7000 ft. of railroad, a steel tipple and electric-power plant. Offut & Bennett, of Greensburg, were given the contract for the railroad work at $17,000.

Oak Creek, Colo.—W. C. Ferguson, of the Empire Coal Mining Co., Denver, has secured a 20-year lease on the property of the Junction City Coal Co., near here, and will spend about $30,000 installing modern equipment preparatory to starting mining operations next fall.

Clinton, Ind.—Edward Shirkie, former president of the Oak Hill Coal & Mining Co., has purchased a tract of coal land along the Chicago, Terre-Haute & Southeastern R.R., and will sink two new mines. It is understood that tipples will be ordered in a short time.

Seattle, Wash.—A new company, composed of German and British capitalists and known as the Issaquah & Superior Coal Co., Ltd., has acquired the Issaquah coal mine and will spend several hundred thousand dollars on improvements and equipment. The company is represented by Albo von Alvenshaben, of Vancouver, B. C.

Publications Received

JOURNAL OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, March, 1912. 120 pages, 6x9 in., illustrated. 35c. per copy. Publication office of the Society, New York.

Some of the papers presented in this issue of the journal are: "Some Tests on Carbureters," by George W. Munro; "Some Refractory Substitutes for Wood," by Charles L. Norton; "Power System of the Pacific Mills," by F. A. Wallace; and "Electric Propulsion of Ships," by W. L. R. Emmet.

METHODS OF ANALYZING COAL AND COKE. By Frederic M. Stanton and Arno C. Fieldner. Technical Paper No. 8, U. S. Bureau of Mines. 22 pages, 6x9 in., illustrated.

The fuel investigations being conducted by the Bureau of Mines had their inception in the work done at the government coal-testing plant, erected in 1904, at the Louisiana Purchase Exposition, St. Louis, Mo., and the analytical methods originally used by the chemists at that plant have been followed, without much change, in the subsequent chemical work of the fuel-testing plants at St. Louis, Norfolk and Pittsburg. The paper describes the original methods (which were those recommended by the committee on coal analysis of the American Chemical Society), and such modifications and changes as experience has shown advisable.

Industrial Notes

The Eastern Manufacturing Co., of Elmira, N. Y., reports that it has just filled several large orders of maple pipe for the Lackawanna and Erie railroads. During the past month the company has been busy supplying pipe for the coal mines. Three carloads of wood pipe, which were recently shipped, will be used for siphon purposes.

The announcement is made that the corporation which has existed for 15 years under the title of the Eureka Tempered Copper Works was, on Apr. 1, succeeded by the Eureka Co., with an increase of capital stock from $100,000 to $250,000. The personnel of the new corporation remains the same as heretofore. Their established line of business will be continued, and with the addition of enlarged facilities and modern equipment the company hopes to aggressively maintain the enviable reputation which it has enjoyed for almost a score of years.

The Bury Compressor Co., of Erie, Penn., announces that it is putting on the market a line of "variable volume" air compressors. These are power, steam or motor driven. It is maintained that the variable volume feature of these machines will fill a long felt want and offers an opportunity for effecting a great saving in air compressor service.

The Cross Engineering Co., Carbondale, Penn., is putting on the market a fireproof mule stall for mines. This is of concrete and steel construction and has already been adopted as standard by several of the larger anthracite mining companies. This new type of construction is made necessary throughout Pennsylvania by the recent enactment compelling all underground buildings to be made of incombustible materials.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The appearance of some tangible evidence of a settlement being reached in the bituminous scale has caused a general easing off in the coal markets. The trade immediately responded to the announcement that a tentative agreement had been effected between the delegates of the miners and operators, by a general softening of prices in all grades. That the present arrangement is only tentative and will not, in any event, become effective for some time has prevented a heavy slump in prices, which still range well above normal. It is hoped in trade circles that the suspension will be of sufficient duration to insure the heavy accumulations of strike supplies being worked off, so that on resumption of work at the mines there will be, at least, a normal demand.

In the Eastern markets, prices have fallen off appreciably, but a feeling of uncertainty pervades the soft-coal trade and there is still a strong demand in that branch, although it is not thought prices will again reach the high level of two and three weeks ago. The situation is more acute in anthracite. While a few more cargoes are still due in the coastwise trade, these are all sold ahead and will mark the completion of the hard-coal shipments until work is again resumed at the mines; the supplies on hand at the large distributing centers will be cleaned up by Apr. 10.

Heavy tonnages have been acquired in the Pittsburg district for speculative purposes, which will, no doubt, be easily worked off during the suspension. The notice of a general advance in wages, as given out by the Frick company, occasioned considerable surprise in trade circles and the market generally is erratic and entirely unsettled. There is great activity in the Ohio trade, due to a freer movement on the railroads and an unexpected demand from consumers short in supplies. Preparations are also being made for an active lake trade as supplies at the head of the lakes are known to be abnormally low. There is an urgent demand for the West Virginia product for shipment to tidewater where cargoes for foreign destinations are being loaded almost daily; at present writing there are vessels at Hampton Roads demanding 300,000 tons of coal. The coal business in Kentucky last month broke all previous records.

The unexpected announcement at the last minute, on the part of a number of the Middle West roads, that they were confiscating fuel, has caused some uneasiness there. However, there has been considerable coal accumulated on speculation and prices are soft, the market breaking Saturday when it was heard that an agreement had been reached in the labor controversy.

The markets in the far West are entirely unaffected by the Eastern situation and the trade is normal and quiet.

Boston, Mass.

Press reports of an agreement in the soft-coal regions knocked the bottom out of what was an active bituminous market all-rail, the only delivery of importance here under present conditions. The volume of spot coal bought during the week, in anticipation of a tie-up, was the heaviest for a long while, and prices well up to $3.25 at the mines were realized in some cases, on ordinary Pennsylvania coals. It is hard to foresee what quotations will be during the next week or two, but it looks as if "strike prices" had once more gone into history, so far as concerns soft coal.

If anthracite barges are put into the bituminous trade, it will mean a largely increased tonnage of the Pennsylvania grades out of New York and Philadelphia. During the flurry we have been going through, very little was heard about quality. The anthracite companies have now practically closed the gate, and after a few more cargoes are shipped, there is no hard coal expected to be available until after mining is resumed. Premiums up to $2 have been paid for coal alongside Boston, but part of this covers the extra water freight on outside tonnage. All-rail, from $1.10@1.75 extra, has been paid for stove and chestnut. The Boston dealers advanced screenings to $3.50 on the first.

Wholesale prices have been as follows:

Clearfield, f.o.b. Philadelphia....	$3.75@4.00
Clearfield, f.o.b. New York	3.75@4.25
Clearfield, *en route*, f.o.b. mine basis	2.35@3.25
Pocahontas, New River, f.o.b. Hampton Roads	4.75@5.00
Pocahontas, New River, Boston, on cars	6.50@7.00
Pocahontas, New River, Providence, on cars	6.00@6.75
Anthracite, stove, chestnut, alongside Boston.......	7.25@7.75
Anthracite, chestnut, all-rail, mine basis.....	4.55@5.30

Water freights from New York to Providence slumped to 75@80c. during the week, on account of the lack of hard coal at the piers. The old figure of $1.40 is still the rate from Hampton Roads to Boston.

New York

Prices on bituminous in the New York market have eased off further, although still considerably above normal. Quotations are nominally about $2.90@3.65 alongside, although there have been some figures named as low as $1.05 at the mines. Most of the bituminous mines shipping this trade are continuing at work and the supplies are good. The large corporations here have facilities for storing a 90-day supply and no serious results are anticipated from a short suspension at the mines.

Considerable surprise and consternation were caused in shipping circles here by the announcement on the part of the Cunard and White Star steamer companies of their proposal to insert a strike and war clause in all contracts. The ocean liners are now obliged to coal for the round trip and each extra ton of fuel thus carried means a ton less of freight.

The situation in anthracite is somewhat more urgent. The hard-coal mines are now definitely closed, the arrivals have ceased and by Apr. 10 all supplies in the hands of the large distributing companies will be cleaned up. It is believed that any consumer caught short after that date will be obliged to pay a high price. Supplies of the steam sizes available at this time are estimated at about 50 or 60 thousand tons, while under normal conditions they are usually about 100 thousand.

Domestic sizes of anthracite sold up as high as $6.50 last week, but wholesale prices f.o.b. New York now, are about as follows:

Broken	$5.50@6.00
Egg, stove and nut...........	5.50@6.00
Pea	4.50
Buckwheat	4.10@4.50
Rice	3.10@3.50
Barley	2.25@2.50

Philadelphia, Penn.

The first week of the suspension of anthracite mining operations finds the trade in this vicinity a little flat. Of course, this is in a measure due to the fact that there is practically no coal for sale by the wholesalers, but notwithstanding this fact, the dealers report that the demand is not abnormal, nor in any way insistent. As a matter of fact, the op-

timistic views expressed by the newspapers regarding a prompt settlement of the trouble between the miners and operators, has probably had the effect of causing householders to postpone any purchases of coal that they really do not require for immediate consumption, feeling that there is a possibility of getting it at the reduced circular prices.

There probably is some ground for the supposition that the suspension will not be of long duration, at the same time there is a feeling that an adjustment of the difficulty is not so near as many are led to believe. This city went into the first week of the suspension not very well supplied with fuel, except in isolated cases. It is understood that the street railway and gas companies are in fairly good shape to stand a prolonged siege, but the majority of other industries, being handicapped for stocking space, have comparatively short supplies on hand, and a month, or six weeks at the most, will find numerous manufacturing establishments seriously embarrassed. It has resolved itself into a waiting game, and the most optimistic do not predict any settlement for a month at least.

Pittsburg

Bituminous—The entire trade, probably, was surprised that the operators and miners reached an agreement at Friday's meeting in Cleveland, though the terms of settlement are approximately what has been expected for some time. Undoubtedly the acute scarcity of coal, as accentuated by the strike in England, had a great deal to do with the settlement. The mines were idle the first day of the week, but the referendum vote will probably result in the great majority starting in between two and three weeks.

There is a large quantity of coal held speculatively, but as the mines are to be idle for some time yet the holders will make every effort to realize on it, and there has been no drop in prices thus far. While the large consumers had stocked up, the smaller ones as a rule have been carrying no important stocks, and there will probably be demand sufficient to liquidate the speculative stocks.

The market is entirely unsettled, but we repeat last week's quotations as representing nominally the market, coal being easier to secure at the figures than was the case a week ago: Mine-run and nut, \$1.50@1.60; ¾-in., \$1.65@1.75; 1¼-in., \$1.90@2; slack, \$1.40@1.50, per ton at mines, Pittsburg district.

Connellsville Coke—To the entire surprise of the trade and the workmen, the H. C. Frick Coke Co. late Sunday night posted notices of an immediate general advance in wages at all its plants. The other operators will follow suit, as usual, and the extras paid at various operations, particularly in the Klondike, where coal is harder to mine, will be continued. The advance was probably prompted by the advance granted in the union districts, the Connellsville coke trade being anxious to keep its industry unorganized.

The coke market has been very unsettled, with light demand and very scant supply. Late last week prompt furnace coke advanced again, and sold at \$2.40, against our quotation a week ago of \$2.25. There were sales on last Saturday at this figure, although it was known that an agreement had been reached in the union bituminous districts, and the same figure is asked today.

Baltimore, Md.

Prices of coal in the Baltimore market have been easier than during the previous week, but the demand continued heavy. Practically all grades of fuel, have dropped from 20@25c. per ton, due to the free movement on the railroads, and a substantial increase in the output. Weather conditions have favored mining operations, and the railroads have handled the traffic in good shape throughout the week. The car supply improved considerably, and there was little delay in getting the product to market.

Although it appears that the strike situation in England will be cleared shortly, the demand for coal abroad still continues brisk. The Consolidation Coal Co. closed contracts during the week for 18,000 tons of fuel destined for Buenos Ayres and Naples, 12,000 going to the South American port, and 6000 to Italy; more shipments are to be made as soon as the loading can be completed.

Local companies are intensely interested in the situation. While the majority of operators here employ nonunion men, there are others who have on their payrolls between 8000 and 10,000 union miners, and if there is a strike, they will feel it.

Buffalo, N. Y.

The bituminous trade is slowing down very fast, and consumers are mostly well supplied, some of them having laid in a six-months stock. There has been a large amount of coal moving and the fact that it has sold at from 50c. to \$1 over the price of a month ago has not kept many from buying. So eager were buyers to get out of the trade as soon as it was safe, however, that it was the regular thing to cancel all orders on the receipt of news from the Cleveland conference that an agreement was virtually in sight.

The selling plan for several days has been to fill orders the moment they were given. Most jobbers have kept in telephone connection with the mines and were able to furnish car numbers often within an hour or two after the order was received, for it was known that the coal would have to be sold again if there were reports of an agreement between the operators and the miners.

Bituminous coal has advanced anywhere up to \$1 over regular prices, which are \$1.60 for Pittsburg three-quarters, \$1.50 for mine-run and \$1.25 for slack, with Allegheny Valley running about as high. Coke has not advanced more than 75c., being regularly \$4.25 for best Connellsville foundry. All will be back to former prices at once if mining is continued.

The anthracite trade has been suspended, according to the reports of shipping agents, who say that they expect no further supplies now. They are inclined to believe that the suspension is to be short, for the supply is by no means equal to the bituminous. Not a ton has been received here for lake shipment and none can be spared now. A little will go West by rail for awhile, but if the suspension should last till June 14, as it did in 1902, there will be much distress the coming winter in isolated sections.

Cleveland, Ohio

The market at this time is practically at a standstill. People who have coal on track and *en route* are laying low for the final settlement, in anticipation of a suspension, which is expected to be from three to four weeks.

There is considerable high-priced coal *en route* from the mines to Michigan, and the shippers' hope is that there will be a suspension. It is feared that with the great amount of coal on track and *en route*, and because of the fact that the larger manufacturers and railroads have made preparations for a strike, with at least from 30 to 60 days' supply on hand, prices will slump heavily unless the suspension occurs.

Columbus, Ohio

Great activity characterized the coal trade in Ohio during the past week as nearly every one connected with the industry believes that a suspension is bound to come and every effort was made to get in the clear. But nevertheless a softening in prices resulted from the abnormally high quotations of the previous week and not many prices of \$2 were paid for steam grades.

It is generally believed that a suspension of from three weeks to a month will have the effect of cleaning up the trade in good shape. It is also believed that a short suspension will not cause any great hardship to any one, but operators do not want the good market to get away from them at this time and for that reason agreed to the small advance in the mining scale which has been tentatively accepted by the miners. The new scale provides for an advance of 5 per cent. for lump, 3c. per ton for all other grades

and 5.26 per cent. in the wages of day men.

The strongest point in the market has been the small sizes which are in demand in every quarter. The mechanical stokers, which are used pretty generally, require the small sizes and thus the strongest grades were nut, pea, slack and coarse slack. Mine-run is also in good demand and prices on grades between mine-run and the small sizes are about the same.

Preparations are being made for an active lake season as reports show that little coal will be carried over on the docks in the Northwest. The indications are good that navigation cannot be resumed as early as usual the coming season; some all-rail shipments will be made to the upper lake region.

There is little demand for domestic grades and the season in that trade is about over. Considerable domestic lump is tied up in the transportation congestion and this will cause a surplus at many points.

Prices prevailing in Ohio fields are:

Hocking Valley	
Domestic lump	$1.75
¾-in.	1.65
Mine-run	1.50
Nut	1.50
Nut, pea and slack	1.40
Coarse slack	1.35
Pittsburg No. 8	
¾-in	$1.70
Mine-run	1.70
Slack	1.65
Pomeroy Bend	
Domestic lump	$2.00
¾-in	1.75
Mine-run	1.75
Nut, pea and slack	1.70
Coarse slack	1.65
Kanawha	
Domestic lump	$1.75
¾-in	1.60
Mine-run	1.60
Slack	1.50

Louisville, Ky.

As a precaution, in the event of a strike of the coal miners, the Illinois Central Coal Co. has purchased thousands of tons of coal which is being stored in the yards at Paducah, for use if the supply runs short.

Coal which can be utilized for steam purposes is in such great demand at present that Kentucky operators are overwhelmed with orders for it. This demand caused the price to jump from $1 to $1.25 a ton in the last few days. Dealers say that, due to the prospective labor trouble, last month broke all coal records in Kentucky. Not only the larger manufacturing concerns and the railroads, but dealers and smaller consumers have been stocking up. While steam coal, is in particularly heavy demand, all kinds of coal are wanted.

Charleston, W. Va.

Except for the observance of Mitchell Day, no time has been lost in the districts along the Chesapeake & Ohio, the Virginian and the Kanawha & Michigan roads and their branches. Along these lines in West Virginia there are about 31,000 miners, out of the 69,000 in the entire state; except for a few thousand in the northwestern portion of the state, practically all the men that would be affected by a strike are in the Kanawha district. Last Saturday the indications were that some of the locals would not respect the instructions of the union officials to remain at work until all differences were settled. When many of the mines did not operate on Monday, further belief was lent to the rumor that some of the men in the Kanawha district were out, but later developments showed that the men were at work and would respect the instructions of the union officials. Of the 31,000 men in this section of the state, only between 9000 and 10,000 or 11,000 at the most would be affected by a strike.

The car supply last week was poorer than the week before. This situation is to be relieved, however, before the end of the present week, by an arrangement between the Chesapeake & Ohio and the Ohio Central, whereby a thousand cars will be sent over to the C. & O., in addition to five engines; in fact, the engines are already in the Kanawha field. While these cars will mean less than a day's allotment for the Kanawha district alone, it will, nevertheless, mean a considerable help to the present car situation. The allotment for the two districts takes about 2000 cars a day, but with only enough cars to run two and one-half or three days a week, the addition of a thousand more from another road will assist greatly in relieving the situation. A large number of cars are expected from other lines, and if these expectations are realized, there will be enough in the two districts to keep the mines running six days a week.

Hampton Roads, Va.

With vessels at Hampton Roads demanding approximately 300,000 tons of coal, a good idea can be obtained of the activity at this port. By actual count there are at the Virginian Railway Terminal and off Sewalls Point 11 steamers and 7 schooners and barges; at the Norfolk & Western R.R. piers and off Lamberts Point 8 steamers, 14 schooners and 10 barges; at the Chesapeake & Ohio Ry. piers at Newport News 26 steamers and 11 schooners and barges.

It is obvious that several of these vessels will be delayed some days, as the mines have only been receiving about a 50 per cent. car supply on an average since the first of March. Almost daily one or more steamers take a cargo of coal for foreign shipment from this port; the British steamers "Weardale" for Montevidio, Uruguay, and the "Llanwern" for Madeira cleared recently with cargoes of steam coal. Earlier in the week the British steamer "Leitrim" sailed for Montevidio, making two cargoes for that port during the past week.

The demand for coal here is prodigious, although the greater portion of the output has been loaded to tidewater. The heavy rains west of this city during the past week have caused considerable trouble; some six washouts have been reported on the Virginian R.R. alone, and, although repairs will be rushed, they probably will consume two or three days at least.

The bids for furnishing the Panama R.R. with coal, in which shippers through this port are vitally interested, were opened in New York last Friday, but up to the present writing no award has been made. The bids this year on New River-Pocahontas smokeless coal average 30c. a ton higher than last year and 50c. a ton higher than two years ago.

Indianapolis

The anticipated failure of the coal supply, due to the impending strike became evident in Indianapolis and throughout the state recently, when the larger coal dealers received notice from the railroad companies that they had begun to confiscate coal shipped over their lines. The coal dealers and large consumers say that this means they will be forced to face the expected coal famine with the supply that has been stored in the last few weeks. Several of the railroads deny that such a notice had been issued, but the dealers say the best evidence is the notification at hand and the fact that the railroads are already taking coal by the carload. Several companies operating in Indiana cities are said to be in the midst of a fuel famine.

The situation in Indianapolis is much better. The opinion prevails that Indianapolis is in good shape to stand a siege, notwithstanding its enormous manufacturing interests. The coal movement has been heavier within the last two months in Indianapolis than ever before. For two months or more the railroads, dealers, manufacturing concerns and the public utility corporations have been expecting a strike Apr. 1, and have been getting ready.

Inquiry of local dealers brought out the information that the retail coal yards are well supplied. The price of steam coal that jumped to $2.50 a ton last week when coal of all grades sold to the highest bidder, is now selling at $1.50. Men who keep an eye on the coal situation expect important developments within a few days, but do not believe the situation is as serious as some would have it appear.

Chicago

There has been a drop ranging between 25 and 35c. per ton in the price of coal

in the Chicago market; declines of 50c. a ton have been recorded.

The chief cause is said to be speculation among middlemen, and the large amount of delayed coal which has arrived. A considerable amount of anthracite has reached Chicago and been stored by dealers closely associated with the producers. Producers of furnace and foundry coke report a strong demand for their product. There has been a great deal of contracting for smokeless mine-run; in the majority of instances the price is $1.10 and $1.25 before and after the first of August, respectively.

Prevailing prices at Chicago are:

Sullivan County:	
Domestic lump	$2.62@2.87
Egg	2.50@2.75
Steam lump	2.50@2.75
Screenings	2.50@2.75
Springfield:	
Domestic lump	$2.75@2.82
Steam lump	2.50@2.75
Mine-run	2.50@2.75
Screenings	2.50@2.75
Clinton:	
Domestic lump	$2.52@2.77
Steam lump	2.50@2.75
Mine-run	2.50@2.75
Screenings	2.50@2.75
Pocahontas and New River:	
Mine-run	$4.25@4.50
Lump and egg	4.25@4.50

Coke—Prices asked for coke are: Connellsville and Wise County, $4.85; byproduct, egg and stove, $4.95; byproduct nut, $4.75; gas-house, $5.

Minneapolis—St. Paul

Coal men in the Twin Cities look for two or three weeks more of inactivity in coal circles, even though difficulties have been practically fixed up with the miners in the bituminous fields. Local newspapers have been giving considerable attention and space to the prospect of a suspension in mining operations which has stirred up the steam market, and manufacturing plants have been buying heavily during the past week.

The dealer in the country has not been in the market for the past month and he will not be buying any stocks until along during the summer months. Coal that was shipped to them a month or two ago has been coming in, but as a whole their stocks are generally low. Tax assessors in the Northwest seem to have the same opinion as elsewhere that coal dealers are legitimate prey against whom assessments should be put up to the limit. This condition always results in the dealer trying to reduce his stocks to the minimum along about May 1.

The announcement Saturday morning of the settlement between the bituminous miners and operators has had a tendency to make a slight drop in prices, although coal on the market is very scarce and very little is coming into the Twin Cities unsold.

Dockmen say they are very busy cleaning up and repairing the docks and will be putting in repairs and improvements from now on until the lakes open up.

St. Louis, Mo.

With the suspension on in Illinois there is practically no market, inasmuch as there is no demand at this time. The market was glutted the latter part of last week with several hundred cars of Kentucky coal at East St. Louis, which proved valuable to those who had failed to lay in a supply. Kentucky mine-run coal sold for 40c. at the mines, with a $1.10 rate to East St. Louis, and something like 150 to 200 cars were sacrificed at this price.

What little market was left was pretty well broken up Saturday, when it was generally known that the operators and miners had reached an agreement for Illinois, Indiana and Ohio. The coal that was mined Saturday was kept on track, and in one or two instances certain mines in the Illinois field worked Sunday; this coal is being held on track and will be gradually worked off at any price the operators may consider good.

Indications are that the suspension here will last about 30 days or six weeks. This, however, will depend upon whether certain operators in Illinois, who, it is thought, may start up right after Apr. 1, will agree to stay out. It is understood that if one whistle blows for work, other mines in the southern Illinois field will start up the next day, regardless of whether it is May 2 or Apr. 2.

There is no anthracite coming in, but a fairly good tonnage of smokeless is arriving on orders previously placed. Coke is in good demand at $4.75@$5, St. Louis. The market opened up on coal held at the mines about as follows:

Franklin County	
Lump and egg	$1.85@2.00
No. 1 nut	1.85@2.00
No. 2 nut	1.60@1.75
2-in. screenings	1.30@1.40
Carterville	
Lump and egg	$1.75@1.85
No. 1 nut	1.50@1.60
Screenings	1.30@1.40
Mine-run	1.25@1.35
Standard	
2-in. lump	$1.50@1.60
Screenings	1.20@1.30
Mt. Olive	
6-in. lump	$1.75@1.85

Portland, Ore.

There is absolutely no change in the coal-market conditions here since last report, prices being unchanged and the demand light on account of favorable weather conditions. While the East and Middle West have had cold weather with snow, according to reports received here, Oregon is having ideal spring weather. The chief topic of discussion now in commercial circles is the coming opening of the Panama Canal and ship tolls, the Pacific Coast standing solidly for free tolls to American bottoms in coastwise traffic.

San Francisco

Deliveries for the past week have been light, nothing coming in from Australia. Shipments from British Columbia aggregated 8200 tons; receipts from the Rocky Mountain district were normal and it is safe to say that more coal was put out to the consumer than was received.

At the present time the wholesalers are carrying about 30,000 tons of Australian. On the other hand, there are no arrivals of this coal due in the near future with the exception of one steamer with a carrying capacity of 5000 tons.

There has been no change in rates and present prices are as follows:

Wellington, British Columbia	$ 8.00
Pelam Main, Australia	8.00
Rocky Mountains	8.50
Cumberland	12.50
Anthracite, Penn	15.00

Financial Notes

The Pittsburgh Coal Co. declared regular quarterly dividend of 1¼% on preferred stock, payable Apr. 25 to stock of record Apr. 13.

The Delaware, Lackawanna & Western Coal Co. has declared the regular quarterly dividend of 2½%, payable Apr. 15 to holders of record Apr. 1.

The directors of the Island Creek Coal Co. have declared the regular quarterly dividend of $1.50 per share upon the preferred capital stock of this company, payable Apr. 1, 1912, to stockholders of record at the close of business Mar. 23, 1912.

The board of directors of the Reading Co. has declared from the net earnings a quarterly dividend of 1% upon the second preferred stock of the company, to be paid on Apr. 11, 1912, to stockholders of record at the close of business on Mar. 26, 1912.

On Jan. 1 bank deposits in the eight districts of Pennsylvania, which will be most seriously affected by the anthracite strike on Apr. 1, amounted to $118,069,951. Eight years earlier, or on Jan. 1, 1904, deposits in banks of the same districts totaled but $66,419,001.

Last February the Reading Coal & Iron Co. realized $4,031,000 from the sale of anthracite, while in February, 1911, its sales amounted to only $2,306,000. The company has not been receiving any higher prices this year, although many of the retailers have been getting an advance of $1 a ton, but with the larger output the Reading has evidently been able to reduce its cost of mining per ton. Last year the February operations resulted in a deficit of $25,000, but this year's sales showed a profit of $287,000. Total sales for the eight months of the fiscal year have amounted to $26,097,000, as compared with $22,490,000 in the corresponding part of last year. The net earnings this year have been $1,014,000, as against $287,000 last year.

Index of Coal Literature

Monthly list of the world's best articles on coal and coal mining

The following is a list of abbreviations used below:
A.E.G.-Ztg. = A.E.G.-Zeitung.
Ann. Mines = Annales des Mines.
Ann. Mines Belgique = Annales des Mines de Belgique.
Berg-Hüttenmänn. Rdsch. = Berg- und Hüttenmännische Rundschau.
Bull. Am. Inst. Min. Engin. = Bulletin American Institute of Mining Engineers.
Bull. Assoc. Ing. Liège = Bulletin de l'Association des Ingenieurs sortis de l'Ecole de Liège.
Bull. Ass. Sucr. = Bulletin de l'Association des Chimistes de Sucrerie et de Distillerie de France et des Colonies.
Canad. Engin. = Canadian Engineer.
Chem. Engin. = Chemical Engineer.
Colliery Guard. = Colliery Guardian.
Compt. Rendus Acad. Sciences = Comptes Rendus de l'Académie des Sciences.
El. Engineering = Electrical Engineering.
El. Jl. = Electrical Journal.
Engin. Contract. = Engineering Contractor.
Engin. Min. Jl. = Engineering and Mining Journal.
Engin. News = Engineering News.
Geol. Mag. = Geological Magazine.
Giess.-Ztg. = Giesserei-Zeitung.
Iron Coal Trades Rev. = Iron and Coal Trades Review.
JB. Berg-Hüttenw. Sachsen = Jahrbuch für das Berg- und Hüttenwesen im Königreich Sachsen.
Jern. Kont. = Jern Kontorets Annaler.
Jl. Soc. Chem. Ind. = Journal of the Society of Chemical Industry.
Jl. Gasbeleuchtung = Schilling's Journal für Gasbeleuchtung und Wasserversorgung.
Jl. Royal Soc. Arts = Journal of the Royal Society of Arts.
Jl. South Afr. Inst. Engin. = Journal of the South African Institute of Engineers.
Kohle Erz = Kohle und Erz.
Mines Minerals = Mines and Minerals.
Min. Scient. Press = Mining and Scientific Press.
Min. World Eng. Rec. = Mining World and Engineering Record.
Mitt. Ver. Moorkultur = Mitteilungen des Vereins zur Förderung der Moorkultur im Deutschen Reich.
Mon. Ind. Gaz = Moniteur de l'Industrie du Gas de l'Electricité.
Montan. Rdsch. = Montanistische Rundschau.
Oesterr. Tonind.-Zeitung = Oesterreichische Tonindustrie-Zeitung.
Oesterr. Z. Berg- Huttenwes. = Oesterreichische Zeitschrift fur Berg. und Hüttenwesen.
Rev. Noire = Revue Noire.
Rev. Univ. Mines = Revue Universelle des Mines.
Rock Prod. = Rock Products.
S. Afric. Min. Jl. = South African Mining Journal.
Stahl Eisen = Stahl und Eisen.
Stein-Braunkohle = Stein und Braunkohle.
Techn. Rdsch. = Technische Rundschau.
Tiefbohrwes. = Tiefbohrwesen.
Transact. Inst. Mining Eng. = Transactions of the Institution of Mining Engineers.
Transact. Manchester Geol. Min. Soc. = Transactions of the Manchester Geological and Mining Society.
Ung. Mont. Ind. = Ungarische Montanindustrie und Handelszeitung.
Z. El. Machb. = Zeitschrift für Elektrotechnik und Maschinenbau.

Note: We shall be glad to obtain for readers, where possible, copies of the papers referred to.

I—GENERAL

An Elementary Text Book of Coal Mining. R. Peel, 15th Edtn., Cr., 8vo., 7¼x4½, 386 pp., Blackie, London, 75c.

Mining Mathematics. S. N. Forrest, Cr., 8vo., 7½x4¾, 312 pp., E. Arnold, London, $1.12 net.

The World's Minerals. L. Ja. Spencer, 8vo., 11+272, 40 illus., 21 diag., N. Y., Stokes, 1911, $2.

Potts' Mining Register and Directory for the Coal and Ironstone Mines of Great Britain and Ireland. 1911, 8vo., 7½x4¾, 470 pp., Railway Gaz., London, 85c. net.

The Finance of a Mine. M. H. Burnham, Min. Mag., Vol. 5, 1911, 6, pp. 444-8, 6 fig., 1 tab. (The growing importance of engineers in dealing with the financial side of mining.)

The Price of Coal. H. Brighthouse, 18mo., Gowans & G., London, swd., 12c. net.

Mining Operations in General. (Le règlement général des mines.) Rev. Noire, Vol. 14, 1911, 367, pp. 332-35; 368, pp. 356-61; 369, pp. 387-88; 370, pp. 415-17; 371, pp. 437-40. (Installations at the pit head and adits, staple shafts; haulage inclines; haulage in roads; engines and ropes; work at the face; ventilation; special precautions against dust; lighting; explosives; pit fires and sudden outbursts of dangerous gases; use of electricity in ground operations; hygiene in the workings; plans and records; various arrangements.)

Modern Coal Mining Plant of Concrete Construction. Cement Engin. News, Vol. 23, 1911, 9, pp. 301-3, 5 fig. (The construction of the Bunsen Coal Co.'s Universal Mines, Clinton, Ind.)

Report of Mission to England and Germany with Reference to the Distribution of Energy in Colliery Districts. F. Leprince-Ringuet. (Rapport de mission en Angleterre et en Allemagne sur la distribution de l'énergie dans les regions houillières.) Ann. Mines., Vol. XX, 1911, 10, pp. 245-355, 24 fig., 5 illus., 3 plates. (State of the question. Distribution in Durham, Northumberland, Westphalia, Rhenish Prussia, and the Saar district.)

Progress in the Coal and Iron Industry in India. Ol. Favarney. (Progrès des Industries du charbon et du fer dans l'Inde.) Rev. Industrielle, Vol. 42, 1911, 50, pp. 494.

Situation of the Mining and Metallurgical Industry of Belgium in 1910. Jos. Libert. (Situation de l'industrie minière et métallurgique de la Belgique en 1910.) Circ. 4316. Comité Central Houillères France, pp. 1-12.

Extensions in Rhenish-Westphalian Coal Mining. (Die Betriebserweiterung im Rheinisch - Westphaelischen Steinkohlenbergbau.) Ernst Juengst, Glückauf, 1911, 51, pp. 1996-2001; 52, pp. 2037-47, 2 tab.

Binley Colliery. Iron Coal Trade Rev., Vol. 83, 1911, 2282, pp. 839-41, 9 fig. (Plan and equipment of a South Staffordshire Colliery.)

II—GEOLOGY

Experimental Geology (2nd series), Part 2. Application of the experimental method to the study of the phenomena of sedimentation; Part 3, Application of the experimental method to the study of orogenic phenomena (formation of mountains.) R. Lecointre. (La Géologie experimentale (2 serie), 2, partie, Application de la méthode expérimentale à l'étude des phénomènes de sédementation; 3, partie, Application de la méthode expérimentale à l'étude des phénomènes orogéniques (formation des chaines de montagnes.) 8vo., 28 pp, Paris, G. Vitry, 1911.

Relation between the Serial Order of Seams and Quality of Coal in the Ostrau-Karwin District. (Beziehungen zwischen Floezfolge und Eigenschaften der Kohle im Ostrau-Karwiner Reviere.) W. Petraschek, Montan. Rdsch., 1911, 11, pp. 482-92, 3 fig. (Gas content and caking power of the coal are important for the identification of the seams. Changes in the properties of the coal proceed in accordance with certain laws and stand in simple relation to the succession of seams.)

The Coals of the East. (Les charbons de l'orient.) Circ., 4329. Comité Central Houillères France, pp. 1-12.

III—MINING TECHNOLOGY

Coal Cutting Machinery. W. B. Shaw, Iron Coal Trades Rev., Vol. 83, 1911, 2283, pp. 879-82, 19 fig. (Paper read before Manchester Assoc. Engin.)

Coal Cutting Machinery. W. B. Shaw, S. Afric. Engin., Vol. 16, 1911, 6, pp. 109-12, 6 fig. (Advantages and difficulties of the use of machines.)

Coal Cutting Machinery. W. B. Shaw, Electrician, Vol. 68, 1911, 11, pp. 420-2. (Various types of machines in use, considered and compared.)

Jeffrey Short Wall Coal Cutter. Brit. Columb. Min. Engin. Rec., Vol. 16, 1911, 11, pp. 331-3, 3 fig. (A new room-and-pillar machine which cuts across the face of the coal.)

Methods of Driving by Gas Engines for Collieries. A. E. L. Chorlton, Iron Coal Trade Rev., Vol. 83, 1911, 2285, pp. 961-4, 4 fig.

Advance in Air Compression. Mines Minerals, Vol. 32, 1912, 6, pp. 339-40, 3 fig. (Single-cylinder, two-stage, electric driven air compressor, with Rogler-Hoerbiger valve.)

Small Bar Mill with Mechanical Cooling Bed. J. Schmitz, Iron Coal Trades Rev., Vol. 83, 1911, 2280, pp. 770-1, 4 fig.; 2282, pp. 844-5, 12 fig. (A cooling bed 400 ft. long.)

On Stone Drills. (Etwas ueber Steinbohrer.) Steinbruch, Vol. 6, 1911, 31, pp. 368-69.

IV—WORKING OF MINERALS

Working Steep, Thin and Gassy Coal Seams. (Abbausteilgelagerter, wenig maechtiger und schlagwetterreicher Steinkohlenfloetzel.) Kohle Erz., 1912, 2, pp. 39-42, 1 fig. (Height of pillars in pillar and subsidence working.)

The Rill System of Stoping. J. B. Wilson, Engin. Min. Jl., Vol. 92, 1911, 21, pp. 1000-2, 2 fig. (A Western Australian method of stoping in narrow deposits.)

Mine Working in Prussia during 1910. (Der Bergwerksbetrieb im Preuss. Staate während des Jahres 1910.) Z. Bergwes. Preuss., 1911, 2, Stat. Lieferung, pp. 71-139.

V—BORING, SHAFT SINKING AND TUNNELING

Novelties in Drills. (Neuerungen in der Bohrtechnik.) Bauwesen, 1911, 21, pp. 159-60. (Hammer Drills by Kummer, Dresden; Driving head by Frankignoul, Liège; New Percussion Drills.)

Deep-boring Hand-Book. Vol. 4. Rope-Drilling (Drilling Wells.) Revised by B. Baak. (Handbuch der Tiefbohrkunde, 4 Bd., Das Seilbohrsystem Brunnenbohren.) Neu bearb. v. B. Baak, Th. Tecklenburg, Lex, 8vo., VII, 132, pp. 54, illus., 27 tab., Berlin, W. & S. Loewenthal, 1911, $3.35.

Deep Boring. (Das Tiefbohrwesen.) Hans Bansen. (Unter Mitwirkung von A. Gerke and L. Herwegen bearb.) 8vo., XX, 517, pp. 688 illus., Berlin, J. Springer, 1912, $3.80.

The Action and Control of Differently Constituted Coal Roofs. W. H. Hepplewhite, Iron Coal Trade Rev., Vol. 83, 1911, 2285, pp. 970-1.

The Freezing Method of Sinking. W. B. Wilson, Colliery Guard, Vol. 102, 1911, 2659, pp. 1181.

Impregnating the Coal Face. (Stosstraenkeverfahren.) Glückauf, 1911, 46, pp. 1908. (Experiments at the Consolidation 3-4 pit. Success attained in only a few instances. Small economic advantage.)

VI—BLASTING, EXPLOSIVES

A Contribution to the Examination of Dynamite Glycerine. (Ein Beitrag zur Beurtheilung des Dynamitglycerins.) F. Hofwimmer, Chemiker-Ztg., Vol. 36, pp. 41-2, 1 fig. (Estimation of glycerine (glycerolin) by nitration and determination of the nitroglycerine obtained, in a specially constructed apparatus.)

Experiments and Alterations of the Charge Limits of Explosives in Accordance with the Sectional Area of the Experimental Gallery. (Untersuchungen ueber die Veraenderungen der Grenzladungen von Sprengstoffen mit den Querschnitten der Versuchsstrecken.) V. Watteyne and J. Bolle, Z. Schiesswesen, Vol. 6, 1911, 17, pp. 321-23; 18, pp. 344-48; 19, pp. 371-2, 2 fig. (Various causes influencing the charge limit. Experimental determination of the charges igniting firedamp and coal dust in galleries ¼, 1 and 2 sq.m. sectional area.)

Contribution to the Knowledge of Explosives. A. Rzehulka. (Zur Kenntnis d. Spengstoffe.) Montan. Rdsch., 1911, 22, pp. 1056-61; 23, pp. 1110-3; 24, pp. 1154-6. (Discussion of the most important explosives and their valuation in practice.)

VII—TIMBERING, PACKING, ETC.

Various Kinds of Pipes Used in Hydraulic Goaf Packing. (Die verschiedenartigen Spuelleitungen im Versatzbetriebe.) Lueck, Ungar. Montan. Ind., 1911, 23, pp. 3-5. (Unlined and wood-lined pipes.)

Timber Used in Mining Operations. H. R. MacMillan, Canad. Min. Jl., Vol. 32, 1911, 21, pp. 685-91. (The Canadian supply of round and sawed timber.)

Mining without Timber. R. B. Brinsmade, 8vo., 309 pp., illus. N. Y., McGraw-Hill, 1911, $3.

Brattices of Wire and Brattice Cloth in Goaf Packing. (Steckenverzug im Bergversatz mit Draht und Versatzleinen.) DC. Glückauf, 1911, 42, pp. 1656-7, 5 fig. (Description of the conditions at the Lothringen colliery, Gerthe.)

VIII—WINDING AND HAULAGE

On Pneumatic Mine-Locomotives. Franz Koneczny. (Ueber Druckluftlokomotiven.) Montan. Rdsch., 1911, 20, pp. 955-7; 23, pp. 1113-5. (Types built by Rud. Meyer, the H. K. Porter Co. in Pittsburg, and L. Schwartzkopff in Berlin.)

Weight and Equipment of Mine Locomotives. G. Bright, El. Jl., Vol. 8, 1911, 11, pp. 986-98, 2 fig., 2 tab. (Locomotives with motor equipment.)

Economical Winding from Great Depths. (Wirtschaftliche Schachtfoerderung aus grossen Teufen.) Moldenhauer, Glückauf, 1911, 51, pp. 1981-92, 37 fig.

Mechanical Haulage in Mines. (Maschinelle Streckenfoerderung.) Ernst Blau. Kohle Erz., 1911, 51, pp. 1289-98, 52, pp. 1313-20, 7 illus., 6 fig. (Chain and rope haulage.)

Electric Main-Shaft Hauling Machines. Alfred Strauss. (Elektrisch betriebene Hauptschacht-Foerdermaschinen.) Bayer, Ind. u. Gewerbebl., Vol. 97, 47, pp. 461-5, 5 illus.

Modern Hauling Problems. R. W. Hutchinson, Cassier's Mag., Vol. 40, 6, pp. 556-60.

The Whitmore Brake and Overwind Prevention Gear. Colliery Guard, Vol. 102, 1911, 2658, pp. 1125, 1 double plate.

IX—SIGNALING

Pit Shaft Signaling. E. E. Beardsmore, Iron Coal Trades Rev., Vol. 83, 1911, 2283, pp. 899, 4 fig. (Read before Assoc. Min. El. Engin.)

X—LIGHTING

Lighting in Fiery Mines. (Die Beleuchtung in den Schlag. wettergruben.) Montan. Rdsch., 1911, 24, pp. 1158-9. (The Friemann & Wolff flat-wick lamp.)

Device for Electric Ignition of Mine Safety Lamps. Chavy, Jean, Liévin, Pas de Calais. Marcel, Delage u. Paul Woog, Paris. (Einrichtung zum elektrischen Zuenden von Grubensicherheitslampen.) DRP. 241, 306, 30 Juli, 1909.

XI—VENTILATION

Ventilation and the Prevention of Dust on the Rand. H. S. Martin, S. Africa Min. Jl., Vol. 9, 1911, 453, pp. 333-4. (The inverted cone system.)

Reversing the Air Current in Coal Mines. F. N. Siddall, Iron Coal Trades Rev., Vol. 83, 1911, 2885, pp. 980-1. (Read to Nat. Assoc. Colliery Managers, South Midland.)

Some Features of the New Mining Regulations. S. Afric. Min. Jl., Vol. 9, 1911, 455, pp. 409. (Ventilation, water and underground supervision.)

XII—MINE GASES, TESTING

The Escape of Gas from Coal. Colliery Guardian, Vol. 102, 1911, 2657, pp. 10,072.

The H. W. C. Apparatus for Instruction and Research in Gas Testing. Colliery Guard., Vol. 102, 2659, pp. 1177-8, 2 fig.

XIII—COAL DUST

Experiments on Liquid Mixtures for Laying Coal Dust. W. M. Thornton, Iron

Coal Trades Rev., Vol. 83, 1911, 2285, pp. 966-7. (Continuation of discussion of paper read before N. Eng. Inst. Min. Mech. Engin.)

Sudden Outbursts of Gas in Belgian Coal Mines 1892-1908. (Die ploetzlichen Gasausbrueche in den belgischen Kohlengruben während der Jahre 1892-1908.) W. Schulz, Glückauf, 1912, 2, pp. 60-9, 20 fig. (Distribution of fiery pits in Belgian coal field. Relation of tectonics to gas outbursts.)

Automatic Watering Valve (Selbsttaetiges Ventil fuer Berieselungszwecke.) Glückauf, 1911, 49, pp. 1927, 1 fig. (The fitting-ball sprinkling valve at Rheinpreussen colliery. Valve opens automatically when the hose pipe is screwed onto main supply pipe, and shuts automatically when pipes are disconnected.)

Dust in Mines. (Les poussières dans les mines.) M. Lemaire, Rev. Noire, Vol. 14, 1911, 372, pp. 459-61. (Indication du procédé; estimation des quantités de poussières nécessaires; essais en présence de poussières de charbon; essais en présence du grisou.)

Present State of the Coal Dust Problem and its Prevention. (Ueber den heutigen Stand der Kohlenstaubfrage und Kohlenstaubbekaempfung.) Hugo Spiel, Montan. Rdsch., 1911, 23, pp. 1104-10, 3 fig.; 1912, 1, pp. 1-11, 3 illus., 3 fig. (Experimental station for testing the various remedies against coal dust. Wet methods; watering and steaming; soaking the coal face; wet zones Kruskopf apparatus;) hygrosopic salts. Dry methods; facing the surface on which dust is formed. Addition of inert mineral dust.)

Experiments on Liquid Mixtures for Laying Coal Dust. W. M. Thornton, Colliery Guard., Vol. 102, 1911, 2659, pp. 1181-3.

XIV—EXPLOSIONS

Accidents in Mines. W. Hanauer. (Die Unfaelle im Bergbau.) Oesterr. Z. Berg-Huettenwes., 1911, 51, pp. 706-7.

Radiations in Explosions of Coal-Gas and Air. W. T. David, 4to., 24 pp., Dulau; London, swd., 25c.

XV—MINE FIRES

Dry Fire-Extinguisher (Trockenfeuerloescher.) H. Wiesenthal, Stein-Braunkohle, 1911, 24, pp. 326-7, 1 illus. (Demonstration of the Theo extinguisher at the Templehof trial ground.)

XVI—RESCUE AND AMBULANCE

Liquid Air Rescue Apparatus at the Makiewka Donety Rescue Station. D. Lewitsky. Compressed Air Mag., Vol. 16, 1911, 12, pp. 6261-4.

Investigation of Self-Contained Breathing Apparatus for Use in Mines. The Report of a Committee of the South Midland Coal Owners, etc. Ryl., 8vo., 10¼x6¼, 102 pp., Cornish Bros., London, $1.25 net.

The New Oxygen-Rescue Apparatus Built by the Draegerwerk-Luebeck. (Die neuen Sauerstoff-Rettungsapparate d. Draegerwerks-Luebeck) Ernst Silberstein, Sozial-Techn., 1912, 2, pp. 25-9, 2 fig., 2 illus.

The Tartsch Cycle Track for Rapid Aid in Pit Accidents. (Das Grubenrettungsrad nach W. Tartsch zur raschen Hilfeleistung bei Unglückfällen, Grubenkatstrophen u. a. m. in Bergwerken.) R. Penkert, Kohle Erz., 1911, 52, pp. 1319-24. (Construction of the cycle; tandem for two members of rescue corps. Equipment; two Draeger apparatus, worn by the riders; two pulmotors, each with two reserve oxygen bottles; Hardtmann box bandages.)

Improvements in Rescue Work. (Neuerungen auf dem Gebiete des Grubenrettungswesens.) Eugen Liewehr, Montan. Rdsch., 1912, 1, pp. 11-5, 1 fig. (Chiefly the arrangement of underground shelters.)

XVII—DRAINAGE, PUMPING, ETC.

Turbine Mine Pumps. Mines Minerals, Vol. 32, 1911, 5, pp. 287, 1 fig. (Comparison from experience with ordinary steam pumps.)

Rateau Pumps for New Pumping Plants. (Rateau-Pumpen fuer neuere Wasserhaltungsanlagen.) Ernst Blau, Kohle Erz., 1911, 49, pp. 1241-8; 50, pp. 1265-73, 10 fig.

Device for Unwatering Pits by the Siphon Principle. (Vorrichtung zum Entwaessern von Grubenfeldern nach d. Hebersystem.) J. Salzmann, Braunkohle, Vol. 10, 1912, 41, pp. 650-53, 1 fig. (Description of new process. Length of time required for unwatering. Cost.)

Sealing off Mine Water. E. B. Kirby, Engin. Min. Jl., Vol. 92, 1911, 21, pp. 986-8, 4 fig. (The mud process by which fine material is forced into the crevices. Elaborate machinery required.)

XVIII—PREPARATION

Mechanical Devices for Quenching and Loading Coal. A. Than, Iron Coal Trades Rev., Vol. 83, 1911, 2280, pp. 763-5, 19 fig. (Translated from "Glückauf.")

A New System of Screening and Loading Coal. Iron Coal Trade Rev., Vol. 83, 1911, 2284, pp. 291-3, 7 fig.

Coal Washing Plant at the Cramlington Colliery. Engineer, Vol. 112, 1911, 2921, pp. 648, 2 fig., 1 plate.

Improvements in the Treatment of Washery Sludge. (Neues in der Schlammaufbereitung.) Th. Moehrle, Koyle Erz., 1912, 3, pp. 49-54, 2 fig. (Practical methods for recovering washery sludge.)

Conveying and Cooling Coal by Aspirated Air. (Zum Kohlenfoerder- und Kuehlverfahren mittels Saugluft.) Schlauf, Braunkohle, Vol. 10, 1912, 40, pp. 634-5. (Cooling the dried coal with aspirated air. Calculations.)

New Check Picking Belt. (Ein neues Kontrollesseband Weise.) Glückauf, 49, pp. 1917-8, 2 fig. (For checking the second picking. Cost small. The new belt has increased the output 265%, the cost being reduced by 46%).

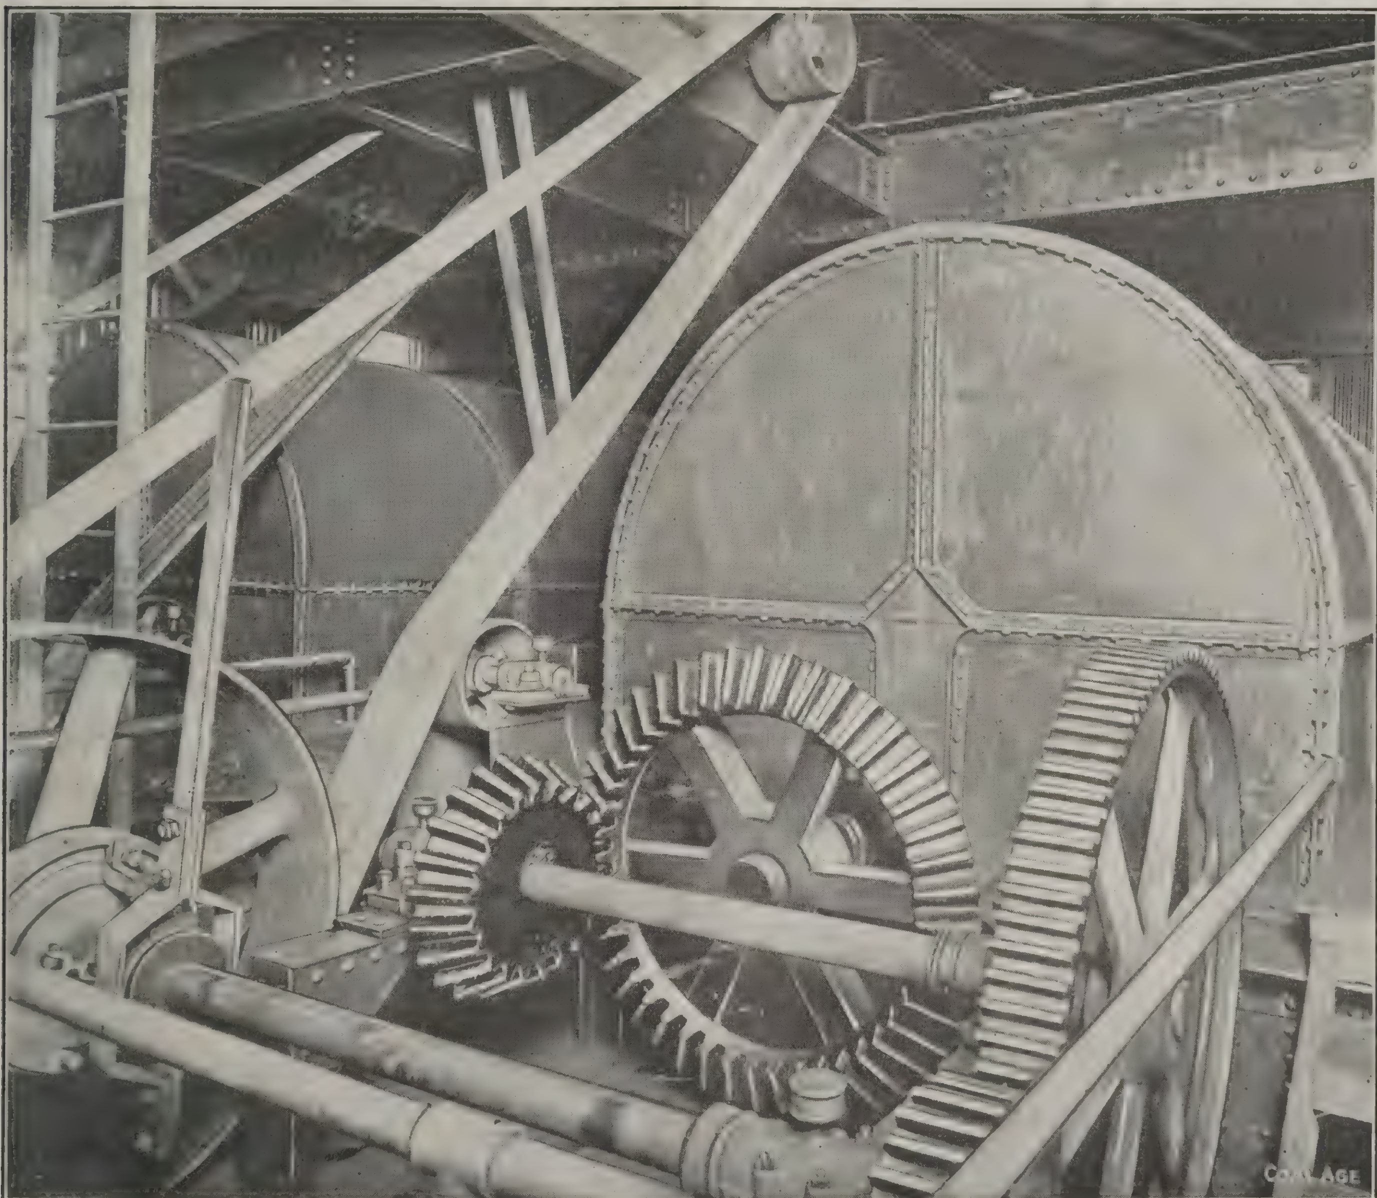
COAL AGE

Devoted to Coal Mining and Coke Manufacture

Volume 1, No. 27.
Issued Every Saturday.
Hill Publishing Company.

NEW YORK, APRIL 13, 1912

Ten Cents per Copy.
U. S. and Mexico, $3 per Year.
Canada, $4: Other Countries, $5.



REVOLVING SCREENS, COMPLETELY INCLOSED IN DUST-PROOF STEEL CASINGS, ANNABELLE TIPPLE, FOUR STATES COAL & COKE CO., WORTHINGTON, W. VA.

A portion of the re-screening room. Two hexagonal revolving screens, 6 ft. in diameter and 16 ft. long, which resize the product of the main shaking screens. Where an excessive amount of coal dust is present, not only is it difficult to keep machinery in good order, but experience has shown that such dust is an actual menace to the safety of the plant, inasmuch as it may burn with sufficient heat to ruin structural steel work. These considerations, added to the inconvenience and discomfort of a dust-laden atmosphere, led to the use of dust-proof casings at Annabelle and point to the extensive use of dust-removing apparatus at a large number of modern coal plants.

The illustration shows what is going on daily in hundreds of mines, both large and small, all over the country—

A Baldwin-Westinghouse Electric Mine Locomotive

getting out the greatest tonnage at the least expense in the shortest time.

How about your mine? You have not realized maximum production if you have not installed Baldwin-Westinghouse Electric Haulage. Let us tell you about its reliability; its low operating and maintenance cost.

Address either company,

COAL AGE

Vol. 1 NEW YORK, APRIL 13, 1912 No. 27

IT is surprising how few coal companies have realized fixed standards of operation. Too little attention is paid to efficiency as a basis of working.

For example, let us assume that in one particular department of a concern, the actual power expenses are $10,000, and that a predetermined calculation indicates they should be but $5000. A power specialist must get busy and effect the change. Less coal and less power must be used for the same output.

If the present expense is $65 a year per horsepower of 3000 hours, every item of cost must be analyzed, and an expense based on standardized conditions must be ascertained. If it is proved the figure should not exceed $48, this standard cost should be set up for the superintendent of power production to aim at.

The foreman who is in charge of the work where power is consumed is not particularly concerned whether it is furnished him at $65 or $48, but it is his business to prevent wasteful use. It is here, then, that another expert must scrutinize items of power use, and determine what reduction can be made in the total annual consumption by the elimination of leaks, wastes and frictional losses, due to such things as lack of alinement and too tight belts. Right here a saving of at least 30 per cent. can be effected in nine out of ten coal-mine power plants today.

It is absolutely essential in perfecting such an efficiency system, to have the item of power, as to production, distribution and use, set up monthly in two parallel columns, one giving the actual, and the other standard results. The officials must then co-operate until facts and theory agree. Other items of expense, such as maintenance, should be treated in the same way, and can well be placed under the direct supervision of a staff specialist.

In the near future, when attention has turned from the task of reforming capital, to the no less important work of correcting labor, the more difficult act of standardizing coal-mine pay rolls will be accomplished. There will be standard time and cost for every task. As conditions change, standard times will be revised, so as always to conform to the highest personal efficiency of the worker. Co-operation of the employee in surpassing standard output will be secured by providing a wage incentive and by permitting *ambition and hope to have full play.* In addition, the workman will be impelled from behind by fear of discharge.

The mine official who doesn't make constant reference in a comparative way to carefully prepared statements of standard costs and daily wastes is surely running a race without a stop-watch, and on an unmeasured track. Only by the use of predetermined costs can we know that our methods are producing results.

If a mistake occurs in the wages of an employee, and he is over-paid, no time is lost in correcting the error. But how about the same man destroying material or killing time? We do not believe that attention to labor charges should be any less persistent or careful, but efficiency losses should receive closer supervision.

The necessary basis for an effective efficiency system includes the rule that "no material shall be issued without a complete requisition, nor shall any special work be permitted without a service order." Some officials object to full requisitions on the ground that they increase "clerical expense." This is not true, for tabulated information, built up from these requisitions, will cost less than an incomplete record secured along independent lines. A requisition is not a requisition when it calls for "as many lamps as the bearer wants," instead of specifying the precise number required to be given.

It is also possible to extend the use of service cards to machines, so as to compare the time and cost of different ones on the same work. The man in charge should not be satisfied if a runner operates one machine for five hours at 100 per cent. efficiency, and then handles another machine for three hours at a like high efficiency. The equipment boss should immediately concern himself with the fact that, *owing to idleness, the first machine only operated at 62½ per cent. efficiency, and the other machine at 37½ per cent.*, assuming an eight-hour day. It is in such cases that economies can and should be effected.

The Sheridan, Wyo., Coal Field

By Jesse Simmons*

A description of one of the largest producing fields in the West. The coal is classed as a sub-bituminous and there are numerous seams of more than ordinary thickness. The field is characterized by the modern equipment installed at the mines. This is the first of two articles on this district.

*Deadwood, S. D.

The Sheridan, Wyo., sub-bituminous coal field is one of the largest in the West. J. E. Stout, state mine inspector, in his report for 1909 says: "I believe it contains more tons of coal than any coal field in the United States west of the Mississippi River, so far as known at this time."

There are 13 seams of coal developed at various points in Sheridan County, three of which are the producers of more than nine-tenths of the tonnage of the district. Geologically, there are but two seams known to exist in the district in the lower horizons. That portion of the field within Sheridan County is about 36 miles east and west by nearly 20 miles north and south. In the adjoining state of Montana, along the Tongue River, these beds outcrop for at least 60 miles. From this it will be seen that Mr. Stout's deductions are no doubt well founded, as here is a vast area underlaid by excellent coal.

Townsite at Monarch, Wyo., a Typical Western Coal-Mining Village

Geology

According to Bulletin 341, U. S. G. S. the 13 coal beds aggregate 144 ft. of coal in seams ranging from 32 ft. down to 5 ft. in thickness. The principal seams worked, the Carney, Monarch and Dietz No. 2 have an average thickness of 14, 30 and 10 ft., respectively.

The main transcontinental line of the Chicago, Burlington & Quincy R.R. passing northwesterly through the center of the district, gives shipping facilities enabling the coal to find a market in Iowa, Nebraska, South Dakota, Colorado, Montana and even as far west as Idaho and Washington. During the year 1910 the mines of this district produced 1,263,657 tons of coal. According to *Mineral Resources* 1909 during the year 1908 the coal was marketed at the mines for an average of $1.52 and during 1909 $1.27, per ton.

The coal is classed as sub-bituminous, since it contains less moisture and ash than lignites and more than bituminous or semibituminous. It has a conchoidal fracture, differing from the bituminous coals, and a bright, black lustre which distinguishes it from lignite. It burns to a clean white ash, making very little clinker and almost no soot. It contains on the average only a trifle more than a trace of sulphur. These properties make it an ideal domestic coal, and although it is lower in heat units than the higher grade fuels, it is extensively used as a steam coal. For the successful consumption of this coal under boilers it is necessary to provide more grate surface and the grate bars must ordinarily be set closer together as the coal has a tendency to break into small pieces while burning. One slight disadvantage that the railroad has encountered in the use of this coal is in dealing with the sparks. This is largely overcome by using stacks with very fine screens. A great many locomotives are equipped with bell and diamond stacks similar to those used on old fashioned wood burners.

The three varieties of mines, drift, shaft and slope, are represented in the district. The seams are thick, as compared with the ordinary coal bed, and the absence of water and freedom from gas simplifies the mining. During the 20 years that the mines of this district have been in operation there has never been an explosion that resulted fatally. The problem of ventilation is reduced prac-

tically to supplying enough air to remove the powder smoke. The only danger which must be guarded against is that of fire. It has been found that the coal is liable to spontaneous combustion and to guard against the large damage which might result it is a usual rule in the district to work the mines by a panel system which enables the operator to close up any portion of the mine completely and effectively.

During the fiscal year ended Sept. 30, 1911, according to State Mine Inspector W. E. Jones, the mines of the district produced 1,744,593 tons of coal, employing 1771 men in the work.

Monarch Mine

One of the largest mines in the district is the Monarch, 10 miles north o Sheridan. It is the property of the Wyoming Coal Mining Co. This property includes drift openings on the Monarch seam and a shaft 85 ft. deep to the Carney seam. The former seam is 30 ft. in thickness and the latter 14 ft. The present workings are confined entirely to the Monarch bed, although the Carney is opened so that within a short time it would be possible to get it in shape for a large production. However, the company has an immense body of coal exposed in the upper seam so that it will probably be some years before the lower is touched. The measures dip to the southeast on a grade of about 2%. The mine and camp are in the Tongue River valley, the main entry being a drift into the coal in the bluffs on the southerly side of the stream.

Main and cross entries are driven 12 ft. wide in the clear to a height of 10 ft. from the bottom of the coal. The panel system is used, rooms being driven 22 ft. wide, 10 to 12 ft. high and 250 ft. long, leaving a 20-ft. pillar between rooms. In drawing the pillars some of the roof coal is recovered as the seam is ordinarily a clean merchantable grade of coal for 18 to 24 ft., and it is endeavored to secure about this thickness. Goodman electric chain-machines are used for undercutting the coal and electric locomotives for hauling, an illustration herewith showing a trip on the way to the tipple.

Monarch's Preparation.

Monarch is quite proud of its preparation, and justly so. After the coal is weighed it is dumped into a conveyor and hoisted to the top of the tipple, dropping into a hopper which holds about 200 tons. This hopper has chutes leading into railroad cars on either side. Through these chutes can be loaded lump or mine-run on each side, or lump on one side and mine-run on the othe. Lump coal is screened over 5-in., diamond-bar shaker-screens, and all coal going through the bars is carried by a conveyor to two revolving-screens, where the different grades, egg, nut, pea and screenings or any mixture may be made. The meshes of these screens are first 2½-in., second 1-in., and third ⅜-in. All coal going over the 2½-in. is egg, everything through the 2½-in. and over the 1-in. is nut, everything through the 1-in. and over the ⅜-in. is pea, and everything through the ⅜-in. is screenings. A chute in the conveyor having 2½-in. bars make it possible to make a product known as "2½-in. slack."

Trackage includes two tracks for loading egg, and one each for the nut, pea, screenings and 2½-in. slack, or eight all told, counting those for the main hopper. The object of the 200-ton hopper is two-fold. In the first place if there should be any delay at the mine it is aimed to have enough coal in the hopper to keep the tipple going until the mine trouble is remedied; on the other hand if there is any trouble at the tipple end, the hopper provides space for dumping coal pending the overcoming of this trouble. The tipple has a capacity of handling 3500 to 4000 tons in an 8-hour shift. The tipple and plant are driven by electricity secured from the Sheridan Electric Light & Power Company.

Monarch as the camp is known, is unquestionably a model coal miners' village. A stranger's first impression is that of a pretty country town, rather than a mining camp. The town, with a population of about a thousand people, has its own system of water-works, is lighted with an arc lamp on each corner and each miners' home has its fence enclosed yard, electric lights and running water. The company offers prizes for the best kept lawns and gardens, and this feature, together with the laudable ambition of its citizens, has made Monarch one of the neatest coal camps in the United States. It includes a modern brick church, a two-story school house, a new brick hospital, a union hall, etc. The officers of the Wyoming Coal Mining Co. are: Mrs. E. M. Holbrook, president and W. G. Birkhaeuser, vice-president and general manager.

Sheridan Coal Co.

The mines of the Sheridan Coal Co., located at Dietz, 5 miles north of Sheridan, are the oldest in the Sheridan field, having been opened in 1897. The earliest opening known is No. 1 Mine, and during 14 years of operation 220 acres of coal have been worked out. At the present time it is not being worked, as the coal is more readily accessible in Nos. 2, 4 and 5, and naturally can be mined much cheaper. These mines can be pushed to produce 5000 tons per day.

The coal is mined on the block system, a method original with these mines, and which has proved to be a complete success. This system requires the expenditure of considerable money in order to develop a given area to the point of production, but, on the other hand, when once in operation it makes cheap mining possible. Another important advantage is the possibility of securing the workings against danger from fire, a menace that threatens occasionally in the mines of the district as has been noted.

Equipment.

The No. 2 mine is worked through a shaft 175 ft. deep, the coal being hoisted in self-dumping cages to the top of the tipple, by an Ottumwa hoist having two, 7-ft. drums and 24x36-in. cylinders. The power plant includes a 500-hp. Corliss engine belted to two, 200-kw. Goodman direct-current generators, rated at

Views of Opposite Sides of the Monarch Tipple

275 volts, and giving 250 volts at the mine for driving Goodman haulage motors. The steam plant includes 3 Kewanee water-tube and 4 Murray boilers, the latter furnishing steam for the air compressor and hoist. A Norwalk air compressor furnishes power for the puncher machines.

Other surface equipment includes a machine shop, which is fully equipped. A feature of this shop is a 15-ft. lathe. A well supplied electrical repair shop is also maintained, where motors are rewound, and other small repairs made to the electrical equipment. Ventilation is accomplished by a 20-ft. fan, having 5-ft. blades, driven at 75 r.p.m. It is direct connected to a steam engine.

The seam, which is known as No. 2, averages 10 ft. 6 in. in thickness, of which 2 ft. of roof-coal is not mined. The coal is undercut by Harrison punchers. Rooms are driven 275 ft. and are on 45-ft. centers, the rooms themselves having a width of about 22 ft., thus leaving a pillar approximately the same width.

The No. 4 Mine

The No. 4 Mine is also working on No. 2 seam. It is a slope mine, the slope extending 300 ft. at an angle of 20°. From the end of this slope the workings extend horizontally out into the coal. The coal is hoisted out in 6-car trips by an Ottumwa single-drum hoist having 24x44-in. cylinders; the drum has a diameter of 5 ft., and 1¼-in. cable is used. The boiler room contains one Murray and two Wilson boilers, which furnish steam for the hoist and fan. Electric energy and compressed air for this mine is secured from the plant at No. 2, a quarter of a mile distant.

One of the features of this mine is the tipple, which is completely equipped for making the various grades produced in the Sheridan field. The mine cars are dumped on a well-planned dump, evolved and manufactured at the mine, and named the "Sheridan dump," or are carried farther to a Phillips crossover dump. The Sheridan dump is used for dumping into a hopper from which the mine-run is drawn, while the Phillips dump is used when it is desired to prepare other grades. Perforated shaker screens are in use in this tipple.

The Sheridan Coal Co. owns 6000 acres of coal land and in addition the coal rights of 800 acres. On this land there are known to exist 5 workable seams, the deepest of which, the Monarch, is 842 ft. below the surface. There are also two seams not classed as workable coal. The drill hole disclosing this coal showed the thickness of the various seams, beginning at the bottom: 22 ft. 6 in., 15 ft. 8 in., 9 ft., 8 ft. 6 in., and 8 ft., a total of 63 ft. 2 in., of workable coal, besides two seams, not workable, of 5 ft. and 4 ft. 8 in. respectively.

The officers of the company are G. W. Megath, president; W. B. McCormick, vice-president, both of Omaha, Neb., H. S. Hopka, Sheridan, Wyo., general manager and Louis Cake, superintendent.

Following is an analysis of the coal, which, by the way, is typical of the product of the Sheridan field:

Moisture	19.63
Volatile matter	35.08
Fixed carbon	39.87
Ash	5.42
Sulphur, Trace	
	100.00
B.t.u.	10,047

Electric Haulage System at the Monarch Mine

Explosion at Sans Bois Mine No. 2

By W. H. Fursman*

More or less dangerous conditions have prevailed in this mine since it was opened in 1902. The practice of driving low crosscuts probably had much to do with the explosion. Board brattices were used. A week prior to the accident, the mine and fan had been shut down for seven days, during which time gas was allowed to accumulate.

About nine o'clock, Wednesday morning, Mar. 20, 74 miners lost their lives as a result of a gas explosion at the Sans Bois Coal Company's Mine No. 2, McCurtain, Oklahoma. Chant No. 2, as the ill fated working is known locally, is a slope mine. The seam pitches about 12 deg. and averages 7 ft. in thickness. There is a dirty band in the middle of the seam, about 24 in. thick, so that in reality there is but 5 ft. of coal. The coal is shot from the solid with Monobel. It has been the custom in driving crosscuts between rooms not to shoot down the top coal. This practice in all probability had much to do with the explosion which occurred Mar. 20.

Previous Explosions

In order to convey some idea of the dangerous conditions which have always existed in these workings, the following list is given of the explosions which have occurred here since the opening of the mine in 1902:

Dust explosion, killing two shot firers	1903
Gas explosion, killing one fireboss	1904
"Windy shot," killing two shot firers	1905
"Windy shot," killing one shot firer	1906
"Windy shot," killing one shot firer	1909

The first day on which work was resumed following the last mentioned explosion, a second shot firer was killed, making two explosions during the year 1909, each of which killed one shot firer. The significant point about this list of disasters is the fact that in the case of all the explosions, the men mentioned above as being killed were the only ones in the mine at the time. Had any one of these explosions occurred during the day time when the mine was filled with its usual working force, the result would have been similar to that of Mar. 20.

When the slope was first opened, the brattices were built of brick or concrete, but of late years this practice has been discontinued and board brattices built instead. As is the case with nearly all board

*Dewar, Okla.

stoppings, the vibration from the shots soon caused them to leak, impairing the ventilation. Such was the condition last fall when the state mine inspector closed the mine for 16 days until proper ventilation was restored. The mine is equipped with an 8-ft. diam. Capell fan, which should have given ample ventilation, had the mine been in first-class condition.

Helmet Men Entering Mine after Sans Bois Explosion

The Tipple of the Sans Bois Coal Co., Chant, Okla.

A Gas Explosion

On the morning of the explosion, the firebosses had "dead lined" several places, among which was the 11th South. At the time the explosion occurred, one of these men was building a brattice from the last crosscut to the face of the entry mentioned. He was found dead near this place with his safety lamp hooked in his belt, and it is supposed that as he worked his lamp came in contact with the gas and exploded, igniting the gas in the face of the entry. Or, it is possible that the gas was driven down the heading to a point where several diggers were waiting for their places to be cleared and was ignited by their open lamps. Several miners were found in this entry, still wearing their coats, as though, when the explosion took place, they had been sitting there, waiting for the fireboss to pronounce their places safe.

The only working places in the mine were the 12th and 13th North and 11th, 12th and 13th South. Although the mine was in a very dusty condition, it is not believed that a dust explosion took place, as there is no evidence of the dust having been burned in any place except near the face of the 11th South. The men recovered from this entry and from the 12th North were all badly burned, some of them beyond recognition, while those in the 12th and 13th South and 13th North were not burned at all, but perished apparently from the effects of the afterdamp.

There is a pump located in the 13th North which was operated by compressed air. Fourteen of the miners found their way to this pump and succeeded thereby in getting enough air to keep them alive until rescued. I talked with one of these men and he stated that he was in the 13th North at the time of the explosion; he did not see any flame, but knew from the concussion of the air that a violent explosion had taken place; he rushed to the main entry, and there met with extreme heat and smoke, through which he knew it was impossible for him to make his escape. With several other men, he rushed back to the pump, found a roll of brattice cloth and built a little room, so to speak, around the pump, and there the men remained about 20 hours. There were 11 men working outside of the 11th entries who made their escape unaided immediately after the explosion. All others, with the exception of the 14 who sought refuge around the pump, lost their lives.

The Rescue Work

Immediately after the explosion, the Government Rescue Station located at McAlester was called upon. Their car and most of their paraphernalia was at Lehigh, Okla., and it was believed could not be brought to the scene of disaster in time to do much good. Mr. Burgess, the only member of the crew remaining at McAlester, was taken to McCurtain by special train with such paraphernalia as he had at hand. However, he was unable to accomplish much until assisted by the rescue corps from Iowa, which was sent for as soon as it was found impracticable to get the crew from McAlester.

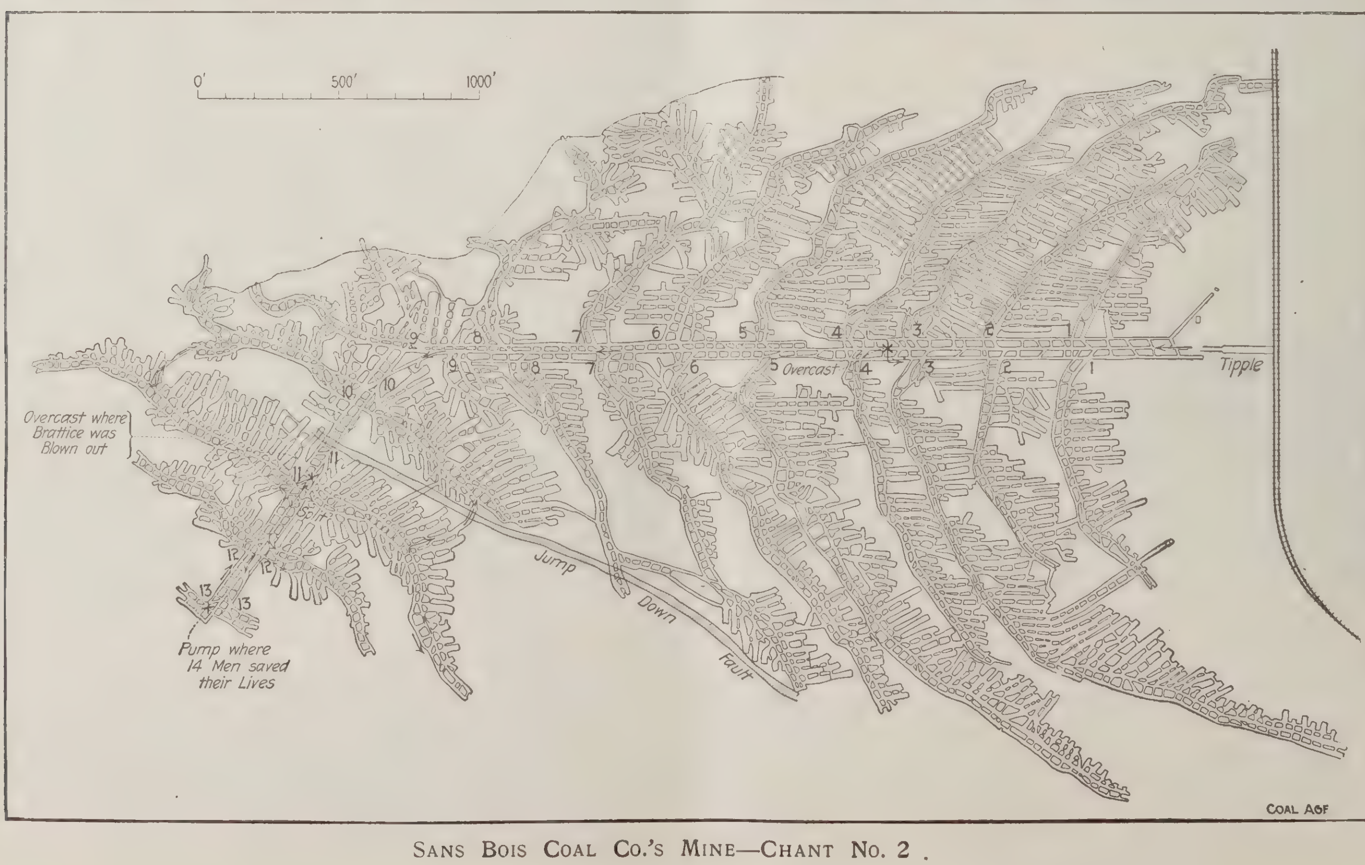
The work of recovering the dead began immediately after the explosion, with practically no one in charge, as the mine manager and his assistants were all in the mine at the time of the explosion. Frank Haley, deputy mine inspector of District No. 3, arrived on the scene at six o'clock Wednesday night and took charge of the work until Chief Mine Inspector Boyle arrived. By that time, Thursday afternoon, ventilation had been established as far as room 12 of the 11th South. On entering the mine, he found the rescue party returning. The men stated that both entries from the 11th South to the face were full of gas and that they were unable to clear them any farther.

After a short consultation, Mr. Boyle ordered the entire party out of the mine with the exception of one man. He gave instructions that they were to remain on top and under no consideration to allow anyone to enter the mine until he came out. This happened about 6:30 Thursday evening.

The Hitch in the Rescue Work

Mr. Boyle and his companion explored the air courses and found that a brattice built in a disused overcast, just outside the 11th entry, had been blown out by the explosion, causing a short circuit of the air. This accounted for the explorers being unable to clear the entries any farther than mentioned. On his return to the surface about 11 o'clock, he found the men greatly agitated over his continued absence. Some of them, believing

Plan Showing Location of Chant Mine



Sans Bois Coal Co.'s Mine—Chant No. 2 .

that he had met with an accident, were in favor of organizing a party and going to his rescue, while others insisted upon obeying his orders and remaining outside until he put in his appearance. Had he remained inside a half hour longer, in all probability a fight would have taken place between the two factions.

Mr. Boyle immediately returned with a party of workmen and rebuilt the brattice over the overcast. As soon as this was completed, they went back to No. 12 room and found that the entry had been cleared for quite a distance inside this place. From that time on, it only required the rebuilding of brattices to establish ventilation all over the mine. As this work continued, other members of the party were removing those dead who were found in the entries, while the crew from the government rescue station with their helmets, explored the rooms and carried out such dead bodies as were found at the working faces.

Not a Violent Explosion

At the present writing, Mar. 27, all the bodies have been recovered except three, which are believed to be under falls of rock in the rooms. These bodies cannot be recovered until the rock has been cleaned up. The explosion brought down the roof in a few places and blew out most of the brattices, but otherwise little damage was done to the mine. The greatest danger with which the first rescuing party had to contend was the possibility that a fire might at any time ignite the gas, causing a second explosion. As they reached the 12th North entries, they found a door partially burned and several cars charred. These fires probably had been smothered by lack of air before ventilation had been established to this point. At this place they found several bodies badly burned, which led them to believe that all others beyond had met the same fate and they gave up the idea that anyone might still be alive at the pump. So instead of pushing forward they began to remove these bodies.

This mistake made it necessary for the survivors at the pump to remain there several hours longer than necessary. In fact it might be said that they were not rescued at all, but remained hovering around the air pipe until their leader, John Kokoski, was sure that he saw a light down the entry. A couple of the strongest of the party, feeling that they were able to reach assistance, made the attempt. Shortly after, those who were unable to get out by themselves were carried out by the rescuers.

Fan Did Not Work When Mine Was Idle

A week prior to the accident, the mine had been shut down as the boilers were undergoing repairs. This necessitated shutting down the fan; so for a week gas was allowed to accumulate throughout the mine. It can be seen readily that on account of the pitching seam, the last gas to be driven out would be that in the face of rooms going to the rise. Of course, before the men were allowed to enter the mine for work, all the working places had been examined by the firebosses and, as previously stated, several of them had been "dead lined." It is quite probable, however, that some of the abandoned workings still contained considerable quantities of gas which it would have been impossible to clear for several days to come, on account of the low crosscuts it had been the custom to drive. It is believed that when the gas was ignited at the face of the 11th South, the concussion forced the gas out of these abandoned workings, thus bringing it in contact with the flame, and thereby greatly increasing the force of the explosion.

By referring to the map it will be noticed that the mine was ventilated by two splits, the main air current entering the slope and passing down to a point just inside the 11th South. From this point, one split ventilated the 11th South, passing out of No. 12 room through the old workings to the air shaft. The other split ventilated the 12th and 13th South, 12th and 13th North and the old workings on the north side of the slope, crossing the slope at an overcast between the third and fourth lifts. It can readily be seen, when the brattice was blown out of the overcast just outside the 11th South, why it was impossible to ventilate the mine any farther than the 11th South until this brattice had been rebuilt.

There is considerable feeling among the miners and the townspeople against the mine officials. It is claimed by some that those who were in charge of the mine showed indifference in carrying on the rescue work. Superintendent Brown's apathy might possibly be accounted for by the sorrow and suffering which he witnessed around the slope mouth after the explosion, as it was enough to unbalance any man who might in any way feel that he was responsible for the suffering. Too much credit cannot be given Chief Inspector Boyle and his deputies for the heroic manner in which they carried on the rescue work.

Another Description of Jed Explosion

By J. H. Williams*

The Jed mine is operated by the Jed Coal & Coke Co., and is situated on Tug River, in McDowell County, W. Va., about 2½ miles from the town of Welch. It is one of the oldest shaft mines in this section of the state, having been opened about 1907.

The hoisting shaft, measuring 32x14 ft., is lined for 85 ft. with concrete. The air shaft is 18x14 ft., with a compartment, 4x14 ft., cased off for stairway and second opening. The shafts are 285 ft. deep and the hoisting shaft is located 200 ft. from the airshaft, where a 24-ft. diam. Guibal exhaust fan is used for producing ventilation.

The Coal and the Methods of Working

The celebrated No. 3 Pocahontas seam is mined at this operation. It has a thickness of about 5 ft. 3 in. and is overlaid with from 12 to 16 in. of fireclay slate. This slate underlies a seam of coal running about 3 in. thick with a stratum of black slate 4 to 8 in. thick above it. The fireclay slate is taken down in all the main and butt entries and propped thoroughly in all rooms and airways.

The mine produces about 700 tons per day and about 100 men are employed on the day shift and 20 during the night. The mine is developed on the panel system with three separate splits for the ventilating current, there being a double intake and a double return. The coal is known to produce marsh gas in small quantities and a line of brattice has to be conducted from the last crosscut up to the working face. Mule power is used for gathering the coal from the face and hauling it to the sidetracks, but from these sidetracks to the shaft it is hauled by electric power furnished to the motors by two 150-kw., 250-volt, direct-current generators. The coal is cut by the night shift with undercutting machines which also are driven electrically.

Precautions Taken to Protect Mine Workers

There were employed at this mine one mine foreman and four men with fire-boss certificates, one of the latter having charge of the night shift. This man was instructed to make an examination of the mine before the day shift came on. The other three men were employed as shot firers. The shots were fired entirely by electric batteries and clay was furnished for tamping, all the miners being instructed to use no other material for the stemming of their shots. Three shots were required for each working place. A center- or breaker-shot was

*Chief engineer, Jed Coal & Coke Co., Welch, W. Va.

placed near the center of the working face and after the coal from this shot was loaded out, two rib shots were fired in succession.

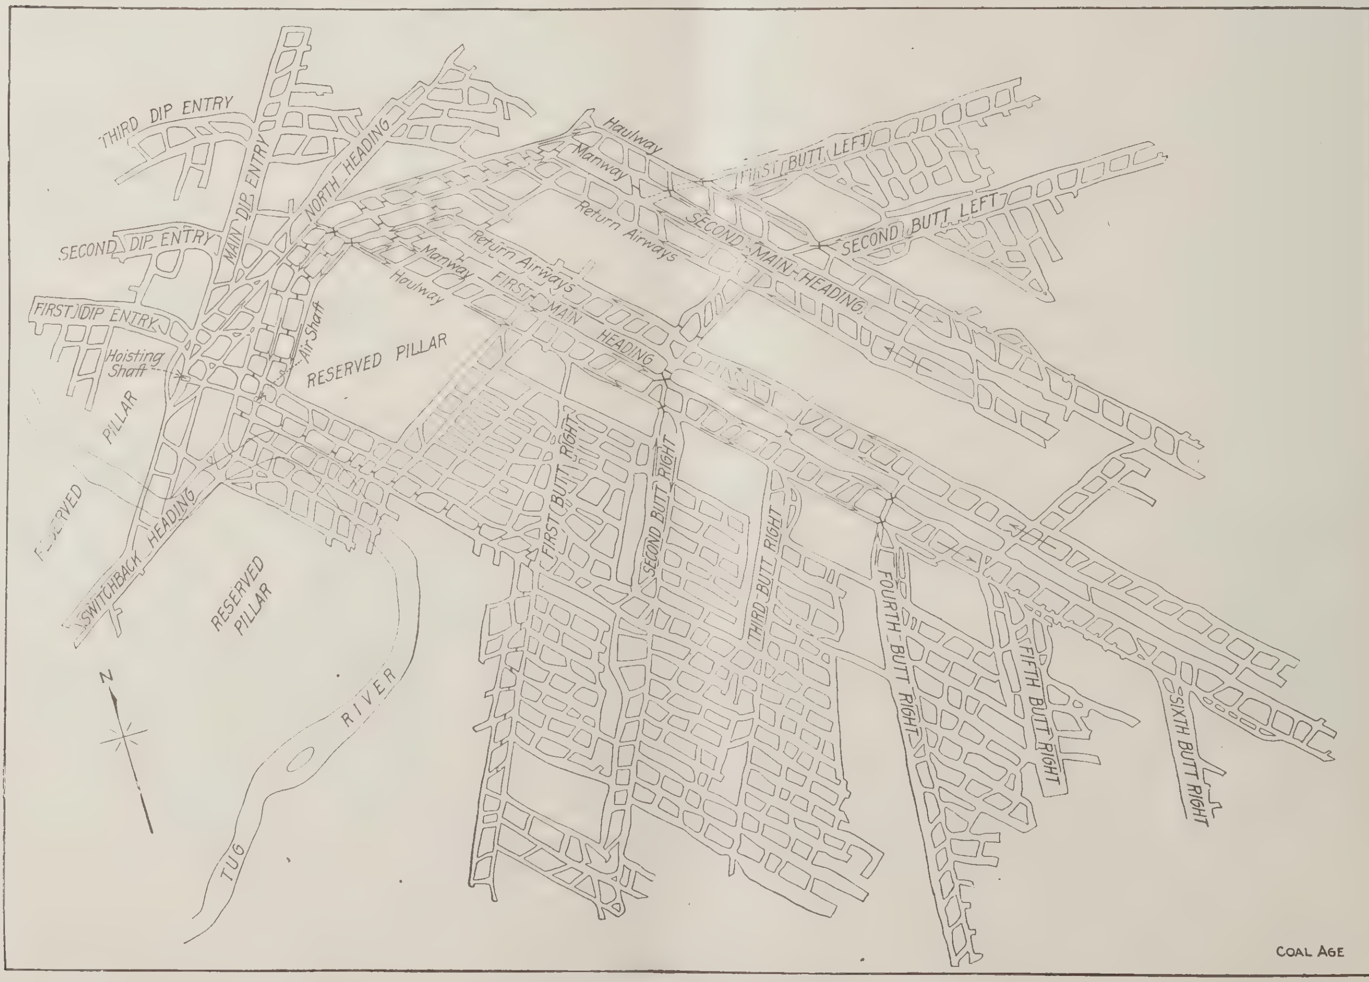
On Mar. 22, 1912, Wm. Leckie, general manager for the company, and Mr. McKent, inspector for the Fidelity & Casualty Co., went through the mine and reported favorable conditions. On the 25th I was through the No. 2 main section and noted that the moisture and ventilation were at least normal.

The Explosion

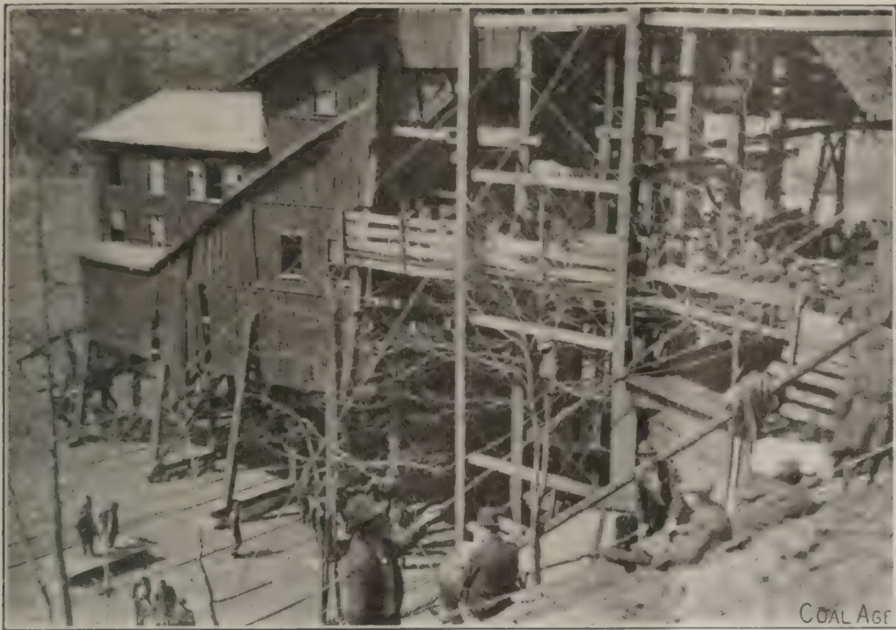
At 8:15 a.m., Mar. 26, 1912, after the fireboss had marked the board stating that the condition of the mine was "O.K.," and 93 men had descended, a gust of smoke shot up through the head frame over the shaft, producing a sound like steam blowing off through a huge pipe. This lasted for about one minute. Coal was being hoisted at the time of the explosion and the car on its way to the cage went into the sump on the right side. The mine foreman, who was at the bottom of the shaft, gave orders over the telephone to the top man instructing him to remove the loaded car from the left-hand cage and landing and to send the cage down. His orders were obeyed and when the car was removed, Supt. O. M. Knauff and F. C. Hendrichs descended with safety lamps.

Jed Tipple and Power House

The cage came up again with ten men aboard who were in the immediate vicinity of the shaft at the time when the explosion occurred. The names of the ten men are as follows: J. S. Henry, Steve Chine, Frank Brudeski, George Savenski, C. F. Woodward, J. Klemens, Joe Egeski, Grant Herndon, Richard White, William Baker and John Owens. By this time some of the outside employees had secured three rolls of brattice cloth, nails, hatchets and safety lamps, and descended into the mine, going 9 ft. north to the door of the mouth at the first main heading, which was reached without bratticing. The doorboy was found at that point still living, but he died shortly after on being brought to the surface.



Mine Workings at Jed Shaft



CROWD AROUND THE TIPPLE SHORTLY AFTER THE ACCIDENT OCCURRED

A short time after the explosion, three men came out through an old airway from the face of the Second butt right off the First main entry. This gave reason for belief that other men were still living in the section ventilated through that entry, but a final exploration of the mine proved the contrary, and it seems improbable that any of the men in that section lived for more than a few minutes after the explosion.

RESCUE WORK

State mine inspectors Nicholson and Grady were on the ground about two hours after the explosion occurred and took charge of the rescue work. Meanwhile a general call was sent out for assistance. Many responded and with a corps of from 50 to 100 men, headed by various mine inspectors, including the chief of the state mining department, John Laing, and able mining men from the surrounding collieries, the work of recovering the bodies was hurried with all possible dispatch, but this work of recovery has nevertheless been comparatively slow on account of the heavy falls of slate resulting from the explosion.

Up to the present writing, Apr. 1, 72 bodies have been recovered. This includes the door-boy who died after being brought from the mine. The remaining eight or nine bodies are believed to be under the heavy falls of slate and it will be, in all probability, several days before all of them are removed.

The cause of the explosion is not yet known, and the State Mining Department will make an investigation next week to determine what was the origin of the disaster. William Leckie, general manager for the company, was in Williamson, W. Va., on the morning of the explosion, and there was no passenger train by which he could get to Jed before 10 o'clock. He boarded a coal train at 6 p.m., and on his arrival immediately went down the shaft. He has been working and directing the recovery of the bodies since that time. Mr. Leckie desires to thank the operators and other individuals in the field for their prompt assistance.

The Problem of Mine Timbering

By R. B. Woodworth *

Interesting cost data in connection with a number of installations of steel mine supports in various sections of the country are here presented in proof of the greater economy of steel as compared with wood. Preservative measures necessary to adequately protect steel in the mines are discussed. The fifth of a series of articles on mine timbering.

After all, does the use of steel for timbering purposes within the mines mean ultimate economy in expenditure, or will its use reduce the cost of production? A few typical examples will suffice to show what has been accomplished in this country up to the present time.

In 1908 at their Maxwell colliery the Lehigh & Wilkes-Barre Coal Company timbered a double-track gangway with 20 in. 65-lb. I-beam collars 17 ft. long between supports, and 8 in. H-beam legs 10 ft. 6 in. high in the clear, weighing, with base plates, 1,720 lb. per set. These took the place of wooden sets made of 24 in. round yellow pine timbers, the cost of which erected was $15.00 per set, weight 5,040 lb. and the life of which was two and one-half years. In view of their probable durability, the steel sets were erected on concrete bases and this added to the cost of installation, which reached a total of $40.00 per set.

PROVEN ECONOMY IN USE OF STEEL

Capitalized at 6 per cent. interest, the value of the steel sets at the end of 15 years will be $95.86 each, while the capitalized value of the six wooden sets needed in that time will be $153.56. At the end of the 15 years, the steel will have a scrap value per set of $12.03, while the wood will be worth nothing, a saving by the use of steel of $69.73 per set or $4.65 per year. The use of steel in English mines has effected a saving of 2c. per ton of coal mined.

The pump house at the Dodson colliery, of the Plymouth Coal Co., is 100 ft. long, 8 ft. high in the clear and 18 to 22 ft. wide. The roof is exceedingly tender and has caused all kinds of trouble in the pump house, especially in connection with the pipes. Before retimbering with steel, 18 in. to 22 in. round timbers were used, on 2-ft. centers, practically skin to skin. It is estimated that the pump room was retimbered once a year. Beginning with Apr. 16, 1910, the 70 sets of wood timbers were replaced by 48 sets of steel. The last steel set was placed Dec. 15, 1910. According to figures furnished by Mr. John C. Haddock, president of the company, the relative costs were:

1. Wood—70 sets; weight per set 4,150 lb.; cost per set f.o.b. cars at mine, $12.00; cost, erected in place, $34.50; total cost, $2,415.00; life, one year.

2. Steel—48 sets; weight per set 1,483 lb.; cost per set f.o.b. cars at mine, $31.47; cost erected in place, including concrete footings, $61.47 per set; total cost $2,889.09, or not quite 20 per cent. more than wood.

Based on its life, the cost per month of a wood set without interest was $201.25. The steel sets have now been in place 16 months; on which basis, their cost without interest has been $180.57 per month. They have shown no signs of

*Engineer with the Carnegie Steel Co., Pittsburg, Penn.

Note—Paper read before the Kentucky Mining Institute, Lexington, Ky., Dec. 11, 1911.

failure at last accounts; the concrete footings, where weakness would first make itself known, are intact, and the pump room troubles seem to be over. Any length of time the framing now stays in place means money saved.

Costs in Kentucky Mines

Development work is now in progress at the mines of the West Kentucky Coal Company, Sturgis, Ky. The seam mined is the No. 9 coal, West Kentucky coal measures, 4 ft. 10 in. thick. At the No. 8 mine, steel timbers are used in the new slope, both for the main entry and air course. The sets in use are composed of a 10 in. 25-lb. I-beam collar and 4 in. H-beam legs. They are spaced 3 ft. 0 in. on centers and lagged with oak plank 3 in. thick on top, and 2 in. thick on the sides. Between the sets, concrete is placed up to a height of 4 ft. This makes a solid reinforced concrete slope from the entrance to the point where the ribs are hard and top good. According to figures furnished by Mr. W. H. Cunningham, general manager of the company, the comparative costs of wood and steel for this mine were:—

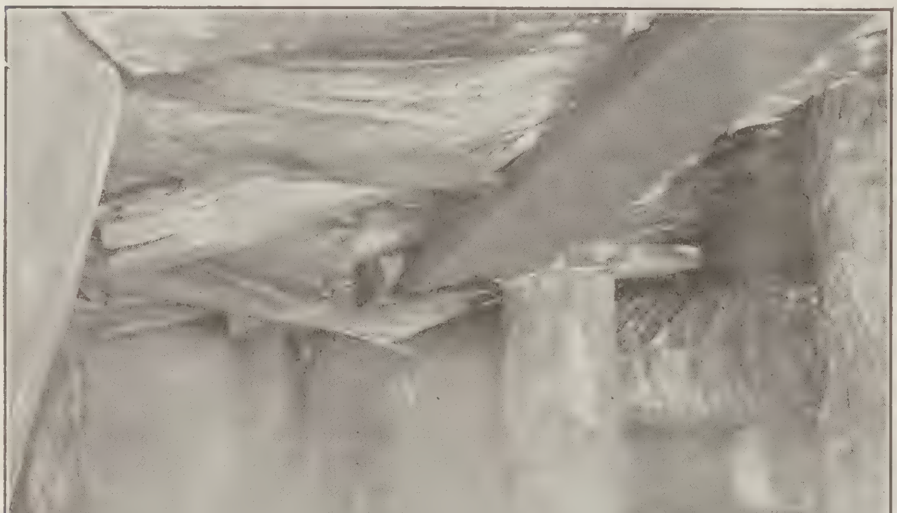
Wood—Yellow pine creosoted; size 12 x 12 in., 264 ft. b.m.; cost at Sturgis, $10.56 per set; cost in place, $15.70; weight 1,575 lb.

Wood—Native white oak; size 12 x 12 in., 264 ft. b.m.; cost at Sturgis, $7.92; cost in place, $13.06 per set; weight 1,340 lb.

Steel—Cost of steel at Sturgis, $9.75 per set; cost of placing $1.00; cost of concrete per panel $5.16; total cost in place per set, steel alone $10.75, steel concreted $15.91; weight of steel sets 425 lb.

Saving in the use of steel without concrete, over native white oak, $2.31 per set, over yellow pine $4.95. Excess cost of steel with concrete, over white oak $2.85 per set, over yellow pine $0.21. This favorable comparison is due to the high unit cost of the wood and to the elimination of waste. The safe uniformly distributed load on the wood collar is 1,200 lb., on the steel collar 26,000 lb. The safe compressive strength of the steel leg is 43,200 lb., while that of the wooden leg is 105,100 lb.; in the one case more than ample, in the other case out of all proportion.

Pump Room, Dodson Colliery, Plymouth, Penn.



Pipeway Leading from Pump Room, Dodson Colliery

It is not easy to obtain cost figures on the use of plain beams for roof supports, although they have found wide and satisfactory application in the bituminous mines of western Pennsylvania, southeastern Ohio, central Illinois and elsewhere. On Feb. 28, 1910, for example, the H. C. Frick Coke Co. had timbered with steel in this way 23 pump houses, 5 stables, 14 engine, motor and locomotive rooms, 10 shaft bottoms, 1 main butt haulage and 3 foremen's offices. Five of these structures were each over 300 ft. in length.

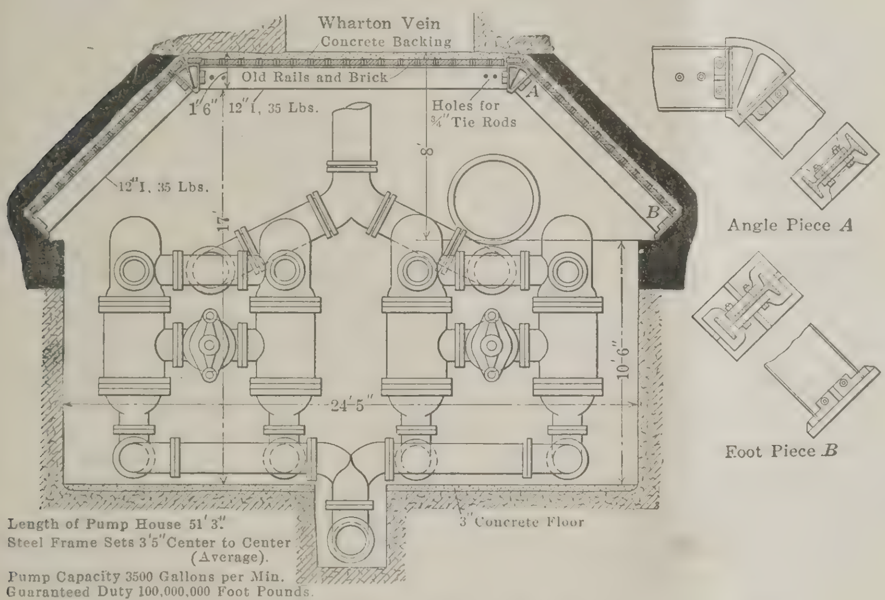
The mines of the Roby Coal Co., Adena, Ohio, have tender roofs, and at one time the haulways were considered the most dangerous in the district. Up to Dec. 31, 1909, as a result of systematic retimbering on a scientific basis, 2,133 steel I-beams and 1,032 8 x 10 in. oak timbers had been placed in Drift No. 1, and 1,490 steel beams and 943 oak timbers in Drift No. 2. The thirty-fifth annual report of the Chief Inspector of Mines for the State of Ohio thus comments on this work. "Even with all this timbering which has been done in the last two or three years

the management informs me that the cost of production is a great deal less than when they attempted to operate without properly timbering the haulways and taking the risk of no one being there when a fall occurred. This demonstrates that in keeping a mine up to a high standard of safety the efficiency is increased and the cost of production decreased."

Secondary Benefits

Apart from the mere question of cost, the collateral benefits which either accompany or proceed from the use of steel in the mines are not unimportant. They are:—

1. Reduced excavation: In the Lehigh & Wilkes-Barre installation the same clear space inside was obtained with steel which required an excavation 4 in. less in height and 32 in. less in width than that needed with wooden timbering.



Steel Timbering in Pump Room, Hazleton Shaft Colliery

In the Dodson colliery the space saved was 2 in. in height and 28 in. in width; in the West Kentucky installation 2 in. in height and 16 in. in width. This does not mean much when the heading is through solid coal, but it does mean a real gain when timbering a mine shaft or in driving main haulage ways where the coal seam is thin, say less than 6 ft. in thickness.

2. Better ventilation: The presence of all stages of decay in wooden mine timbers means vitiated air and discomfort, possibly ill health to the miners. One but needs to walk through a steel-timbered heading to note how much better the air conditions are made; not to mention the smaller resistance that steel offers to the passage of the air currents.

3. Less dust catchment area: Everyone knows now that coal dust is explosive and its accumulation on mine timbers a constant menace. The smaller area of the steel timbers and the ease with which they may be cleaned adds to their value in this direction.

4. Fireproof character: If there were no other considerations favoring the use of steel within the mines, this one would be sufficient. Fire zones underground, shafts, pump houses, powder magazines, locomotive rooms, mine-boss shanties and stables, need protection by the use of fireproof materials of construction. Fire-proof structures underground mean safety and mine insurance and therewith incalculable reduction of expense in maintenance and replacement.

Preservative Treatment of Steel

Like wood, steel is subject to deterioration in the course of time but the process takes much longer than in the case of wood. This action may, moreover, be prevented and the durability of steel, on which its economic advantages are based in part, may be much enhanced by simple means.

The corrosion of structural steel within the mines is not so serious a problem as it is above ground. The standard objection, based on what is alleged to have happened in the case of rails exposed to acid mine water, has no real validity as concerns the use of structural steel for mine timbering. Rail steel is not structural steel. Rails are laid naked, as a rule in contact with the sulphur in the debris which usually covers the track, and frequently wet by running water; moreover, their tops are polished by passing wheels and thus kept in the best condition for the attacks of corrosion. Far better than *a priori* reasoning on this subject are the facts of experience. The steel mine timbers installed by R. V. Norris in 1897 at the foot of Stearn's Shaft, Susquehanna Coal Co., are in use to-day practically unharmed by the lapse of time; so also are those installed in the same year by S. D. Warriner and W. A. Lathrop in the pump room at Hazleton Shaft Colliery, No. 40 Slope, Lehigh Valley Coal Co., and likewise those installed in 1896 by J. A. Ede at No. 1 Shaft of the Spring Valley Coal Mines, of the Spring Valley Coal Co. in the northern Illinois bituminous coal district. Surely 16 years of service suffices to give steel a just claim to permanence.

Steel for mine timbering should not go into the mines unpainted, unless it is to be covered with cement. No one would think of using it unpainted above ground unless so protected; and the principles of right use are the same in both cases. But if well painted before installation, there is no real reason why the timbering should not outlast the life of the mine without renewal.

A paint which will chalk, or peel, or blister, or alligator and go to pieces on the outside of a house, will stand up on the inside and look well until it gets so dirty or so old one is tired of it and wants a change, and even then the work underneath is just as good and fresh as when the coat was first put on. Now, conditions within the mines are analogous to those within the house. The causes which destroy paint films above ground are not here operative, and that is the reason why paint put on beams in the mines 16 years ago is still there and doing its work of protection to-day; and why we may be quite confident that when we put painted steel in the mines, it will do service, without renewal, as long as needed.

Effect of Mine Water

The effect of mine water has been much exaggerated. Laboratory and service tests show that the prevention of its deleterious action on steel mine timbers requires only the careful selection and application of good paints; an inhibitive first coat with an excluder second coat well rubbed in on clean surfaces. The first coat should be preferably red lead or natural iron oxide, the second coat a good graphite. The graphite should be made from the ore, for paint purposes, not from the refuse left in other processes of manufacture. Just as it is an economic crime to use wood in timbering permanent mine headings, so it is an economic crime to trifle with poor paint on surfaces of prospective permanence, not readily accessible for repainting. After all, the main cost of painting is the expense for labor and it does not pay to scrimp the paint.

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Nonfreezing Concrete Mixtures

The following data are taken from two recent issues of the "Quarterly" of the National Fire Protective Association:

The amounts of salt and calcium chloride required to keep water from freezing at different temperatures are tabulated below. The salt should be thoroughly dissolved or the results will not be satisfactory. Calcium chloride is said to be superior to sodium chloride in that it does not corrode steel tanks and the hoops of barrels. Where calcium chloride is used the wooden barrels should first be well coated inside with asphaltum, or a mixture of crude paraffin and resin, to prevent the shrinking of the staves and subsequent leakage:

FREEZING POINTS OF SALT SOLUTIONS

Common Salt (Sodium Chloride) Pounds per Gallon	Freezing Point, Degrees Fahrenheit	Commercial Calcium Chloride Pounds per Gallon	Freezing Point, Degrees Fahrenheit
½	24 above zero	½	29 above zero
1	18 above zero	1	27 above zero
1¼	15 above zero	1½	23 above zero
1½	12 above zero	2	18 above zero
1¾	9 above zero	2½	4 above zero
2	6 above zero	3½	6 below zero
2¼	3 above zero	4	17 below zero
2½	1 above zero	4½	27 below zero
3	3 below zero	5	39 below zero
3½	8 below zero	5½	54 below zero

Glycerin is recommended for use in chemical fire extinguishers. It has no effect upon metals, but has a tendency to disintegrate rubber. It has been stated, however, that the continued use of glycerin in water renders it liable to a decomposition that would develop compounds having a corrosive action on metals. When using glycerin it should be remembered that one gallon weighs 10½ lb. The following proportions may be used:

FREEZING POINT OF GLYCERIN

Glycerin, Pounds per Gal.	Temp. Solution Will Withstand
3¼	+10 F.
5¼	—10 F.

Denatured alcohol has advantages over both glycerin and calcium chloride as a nonfreezing element in water solutions, for it has no injurious effect on either metal or rubber. A solution of about 50% is inflammable; however, it would rarely be necessary to have a solution of over 30% alcohol.

FREEZING POINT OF ALCOHOL

A 20% solution freezes at +10 F.
30% solution freezes at — 5 F.
40% solution freezes at —20 F.
50% solution freezes at —35 F.

Gas Engines for Collieries

By Alan E. L. Chorlton

Gas engines are being largely used at British collieries for the generation of power. The gas is either generated in producers or in coke ovens. Producers can be sometimes made to yield such profits from byproducts, where the fuel is of low grade, that even without using the gas produced, the installation will justify its erection.

Paper read before the Midland Institute of Mining, Civil and Mechanical Engineers.

It will be readily granted that gas engines occupy the leading position among all the agencies now used for the generation of power.

The use of gas power in collieries has been already much advocated by far-seeing engineers, because it is more economical than other methods of making use of the stored up energy in coal. Even with the use of such gas generators as have no provision for byproduct recovery, the economy secured is from two to three times greater than can be obtained with the ordinary steam systems now in vogue. And this is even more apparent when the plant works by steam and for only one shift a day. Large banking and radiation losses result from the inactivity of the plant during the night.

In the past, many authorities had doubts whether gas engines could be relied on as power producers. These doubts probably account for their comparatively slow progress in popular favor. But increased experience has now fully succeeded in overcoming former weaknesses.

For Poor Fuel or Economical Use of Good Fuel

The most economical processes of gas generation for power purposes are either those which use mainly a fuel of little or no market value, or such processes as produce a considerable quantity of gas as a byproduct, and yet are complete and commercially profitable in themselves. As an example of the first, the ammonia-recovery producer uses combustible nitrogenous material from belt pickings, tips, etc., mixed, perhaps, with some coal, the whole being of low market value. This produces a large amount of power gas and ammonium sulphate as a byproduct. In the second class is the byproduct coke oven, using fine coal and producing furnace coke, with many byproducts and a considerable residuum of gas available for power or other purposes. There are combinations of the two, but, so far, they do not appear to have been developed practically, although it is possible that still further economies will be secured by their use.

The distinctive features of the two methods are as follows: When operating a byproduct coke plant (1) the coal must be of the coking kind; (2) the percentage return on capital will be high, even when the value of waste gas is not considered; and (3) the free gas for power purposes in proportion to first cost is low. When operating an ammonia producer: (1) Any poor fuel containing up to 40% of ash can be used; (2) the percentage return is high only when the gas is sold or profitably used; and (3) the available amount of free gas for power purposes is great. Table 1 has been prepared from information received from the manufacturers of large plants of both types, and even if the results obtained in practice do not show so favorable a result, the return on capital is still high.

Use Gas Producers If Much Gas Is Needed

Profitable results can be obtained from large Mond gas producers by the use of cheap or refuse coal, but their economies can only be of avail if there is sale or profitable employment for the large quantities of gas produced. This condition might somewhat limit their use to large

power companies or groups of collieries. On the other hand, the byproduct coke plant gives a higher return when the lack of use for the waste gas makes it impossible to set a value on it. From the particular point of view of power production for the single colliery of 3000 hp. and its direct application, Table 2 has been prepared on a horsepower basis.

Most English collieries have enough of such waste products as will yield sufficient nitrogen to render them suitable for use in a byproduct gas producer. Hence the proportion of such waste fuel has been made large in making this comparison. The important point about either scheme is that the gas for power is obtained at a very low cost—that is, at a low running charge for fuel, and obviously at a great economy over the usual plan of burning saleable coal under boilers. The values for the above tables are primarily governed by the load factor.

In development of these plans, a combination gas generator might be employed, having continuous vertical retorts (such as are now used in town gas works) which would feed coke direct into a producer beneath. Suitable regenerators could be added to utilize the waste heat of the escaping gases. The economies that can be secured in suitable cases by combining with other power consumers, or with power supply companies, in the use of these processes, so as to dispose of the excess power or gas at times of light loads, etc., are not here considered.

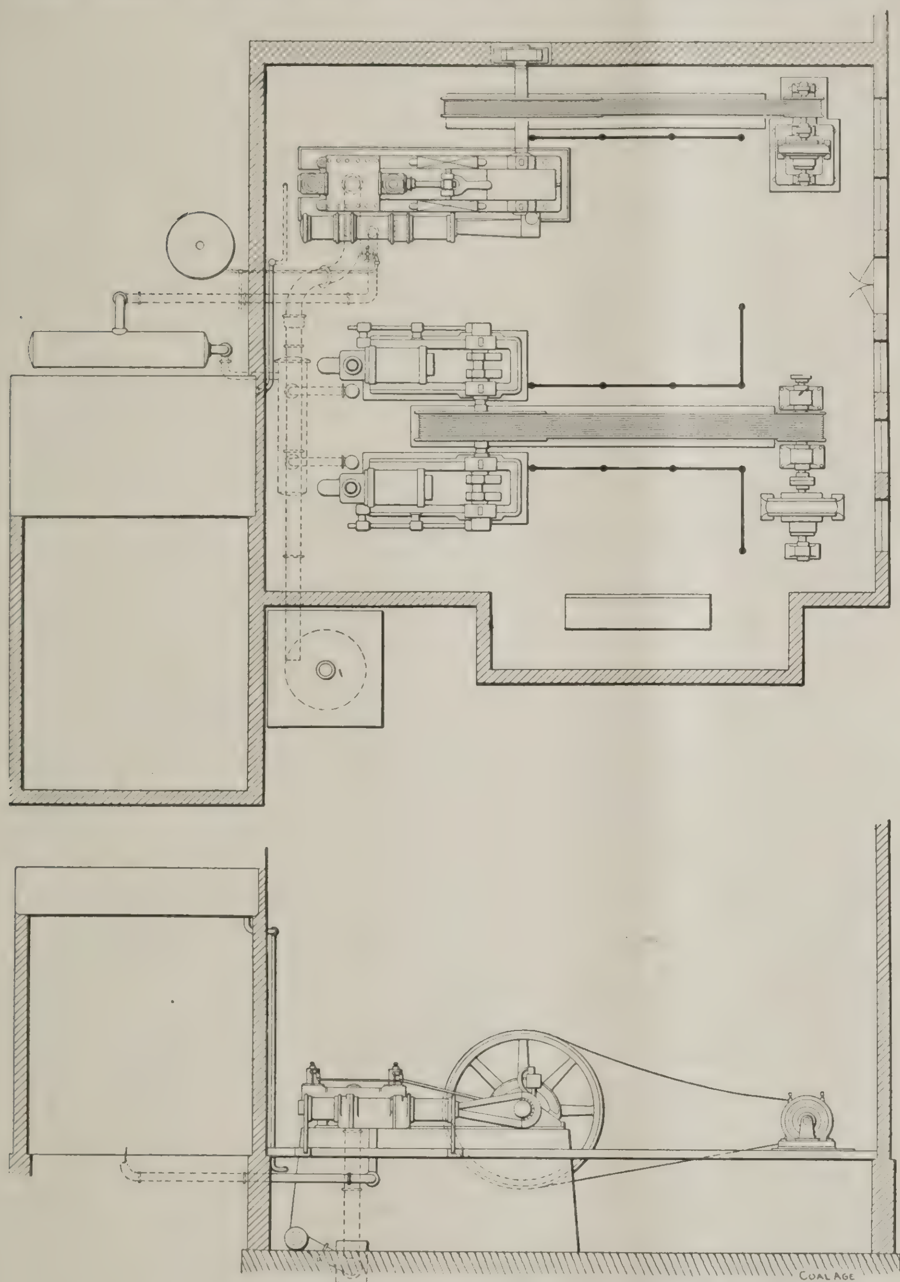


Fig. 1. An Engine Using Gas from Simon Carvés Ovens, Wharncliffe Silkstone Colliery, England

Clean Gas More Reliable

For the satisfactory use of any gas in large engines, be it coke-oven or producer gas, a thoroughly adequate cleaning plant must be provided, which will amply repay its cost in the increased reliability of the engines and in the reduction of cost for upkeep, etc. Great stress must be laid on this point, and it is advisable to lay down a larger plant than is usually offered in competitive tenders.

Continuity of gas supply is, of course, absolutely essential, often rendering advisable the provision of large holders. For producers using poor fuel, these holders, while advantageous, are not necessary, as the producer can be kept at work continuously for long periods, and will respond quickly in output to meet sudden demands.

TABLE I. RESULTS FROM COKE OVENS AND MOND PRODUCERS CAPACITY OF 90,000 TONS OF COAL PER ANNUM (VALUE OF GAS INCLUDED)

(1) Byproduct Coke Ovens	
Capital stock of complete plant...	$219,150.00
Costs	
Coal, 90,000 tons at $1.7045......	$153,405.00
Running charges, including taxes, labor, superintendence, steam power, lime, oil, repairs, stores, etc., at $0.60875 per ton......	54,787.50
Sulphuric acid at $8.52 per ton...	9,238.39
Interest and depreciation at 10%.	21,915.00
Annual cost..................	$239,345.89
Gross Profits	
Sulphate at $58.44 a ton........	$68,374.80
Tar at $4.87 a ton..............	17,532.00
Coke at $2.92 a ton.............	184,086.00
Crude benzol at 8.12c. per gal....	18,262.50
Surplus gas at 0.0812c. per unit..	12,272.40
Gross annual receipts.........	$300,527.70
Net profits....................	$61,181.81
(2) Mond Gas Producers	
Capital stock of complete plant..	$253,240.00
Costs	
Coal, 45,000 tons at $1.7045......	$76,702.50
Coal, 45,000 tons at $0.9740......	43,830.00
Running charges, including taxes, labor, superintendence, steam power, repairs, stores, etc., at $0.60875 per ton............	54,787.50
Bags and packing sulphate......	5,844.00
Sulphuric acid at $8.52 per ton...	30,681.00
Interest and depreciation at 10%.	25,324.00
Annual cost..................	$237,169.00
Gross Profits	
Sulphate at $58.44 a ton.........	$210,384.00
Tar at $3.65....................	13,149.00
Surplus gas at 0.0812c. per electrical unit.....................	79,137.50
Gross annual receipts.........	$302,670.50
Net profits....................	$65,501.50

TABLE II. RESULTS FROM A MOND PRODUCER PLANT FOR A COLLIERY REQUIRING 3000 B.HP., USING A HIGHER PROPORTION OF WASTE FUEL (VALUE OF GAS NOT INCLUDED)

Capital cost of complete plant....	$64,284.00
Costs	
9,600 tons of carbonaceous shale..	nil
900 tons of belt pickings........	nil
1500 tons of waste slack at $0.9740	$1,461.00
600 tons of washed slack at $1.9480	1,168.80
Running charges, including taxes, labor (including packing), steam power, repairs, stores, etc., at $0.60875 per ton............	7,670.25
Sulphuric acid at $8.52 per ton...	3,238.55
Interest and depreciation at 10%	6,428.40
Annual cost..................	$19,967.00
Gross Profits	
Sulphate at $58.44..............	$22,207.20
Tar at $3.65....................	876.60
Gas (not included)	
Gross receipts...............	$23,083.80
Net profits....................	$3,116.80

Low-grade Gas Needs High Compression

If there is any likelihood of considerable variation in calorific value from whatever reason, be it change in fuel or other cause, precautions should be taken in the design of the engines themselves to meet it by excess of capacity, the adjustability of compression, and other provisions.

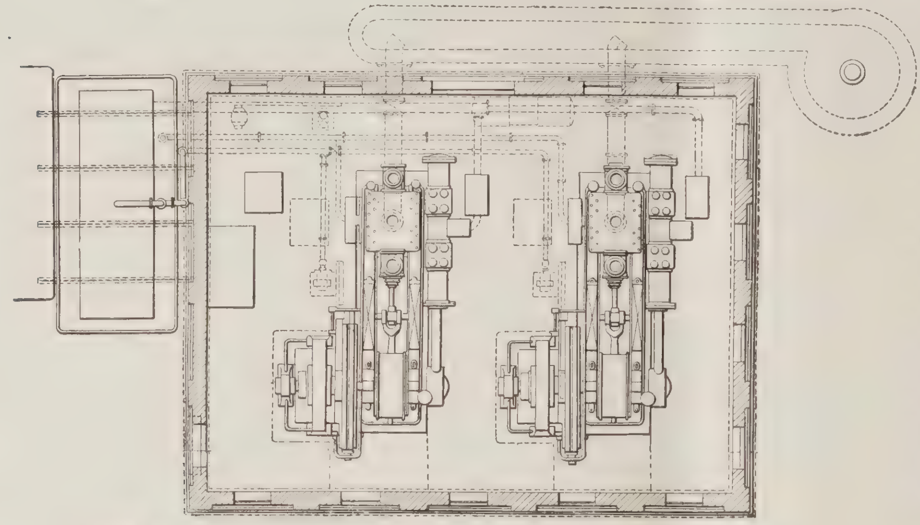
may be stated that for large engine work, the mean pressure effective in the cylinder in order to carry a continuous full load should not be more than 70 lb. per sq.in. when producer gas is used. This pressure may be increased to about 80 lb. for coke-oven gas, and an engine working on such a gas is therefore rather more than 10 per cent. more powerful than when working on producer gas.

in labor, maintenance, etc.; and the writer would propose to adopt the same principle in the design of the various schemes which follow.

The Electric Scheme

The method usually adopted in the utilization of gas power for collieries is to convert the energy at once in a central station into electric power. This scheme has many advantages, of which flexibility is the greatest followed by high efficiency. But the possibilities of other methods should not be overlooked.

A gas-driven electric station is, in general layout, similar to central stations operated by steam engines. The units are laid out generally, so that one side of the station has the inlet gas main and the exhaust-discharge pipes, and the other side the electric connections and the switchboard. An important consideration in connection with the running of a gas station is the cooling water necessary for the engine, although this is much less in quantity than is required for steam turbo-condensing stations in the proportion of 1 to 5. The necessary compressing plant and storage tanks for starting up the engines are installed in the cellar made by



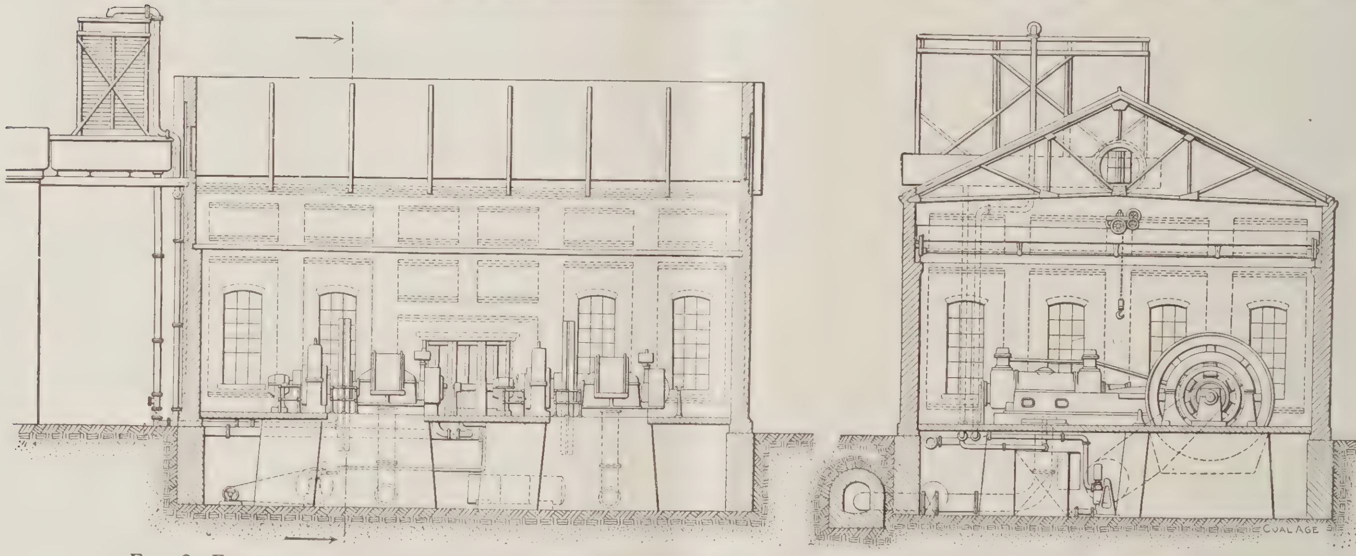


Fig. 2. Engine Installation at Rockingham Colliery. Gas Used Is From Koppers Coke Ovens

Turning now to the engines themselves, the only material change needful to fit them for operating indifferently on high-grade coke-oven gas, or low-grade producer gas, is a provision for regulating the degree of compression. Thus, for a high-grade coke-oven gas, a compression of about 100 lb. would be used, while for low-grade producer gas it might be raised as high as 150 lb. In other particulars the engine will be built in the same manner, although with an intensely active gas, such as coke-oven gas (with its high content of hydrogen), it is advantageous to scavenge the cylinder of air effectively, and to provide additional water cooling so as to minimize the risk of preignitions, with their attendant detriment to the reliability of the engine. It

Five Applications of Gas Power

The possible methods of application of gas engines to the many mine requirements are mainly four in number, namely: (1) Electric, (2) hydraulic, (3) pneumatic, (4) mechanical or direct, and (5) various combinations of these four. Each scheme has certain advantages, and so the greater number of modern collieries use most of them in part in their general layout. Their relative positions in popular favor may have to undergo some alterations, especially if there is any further restriction in the use of electricity underground. In the latest steam-driven collieries all the power units, as far as possible, have been installed in one house on the surface, in order to secure the advantages of the single central station,

the foundations, such a cellar forming in modern practice an effective and well lighted basement to the engine house. Boilers normally heated by the exhaust gases are necessary for the various steam requirements of both the compressing plant and the gas producer.

Suggested Modification of Hoisting Methods

Another arrangement of a gas-driven electric central station has been devised by the writer, whereby considerable economies are obtained in capital expenditure. The *raison d'être* of this scheme is, that where hoisting is the principal absorbent of power in a colliery, it should receive most consideration in a layout. In an all-electric scheme, the use of regener-

ative compensator sets, between the generator and the hoisting motors, accounts largely for the considerably higher first cost of electric hoisting, as compared with steam methods. In this scheme the writer proposes to drive the compensating regenerative sets direct from the gas engine, thus replacing the three-phase motors by ropes and saving the capital cost of these motors, together with that of the main generator in the central station, but adding thereto the cost of the rope drive. The difficulty of running the central-station machines in parallel is a disadvantage, but the machines may be arranged in size to compensate for this, so that one standby or one unit is common to the whole. The station thus consists of a number of flywheel direct-current machines, all rope driven from gas engines. If it is essential to use three-phase high-tension current as well, then such generators must be added. Before proceeding further, a brief description of some such layouts will be given.

Shelton Iron, Steel & Coal Co.'s Power Station

The Shelton station contains two 400-b.hp. two-cycle gas engines, driving directly 500-volt direct-current generators. These sets have been in operation now for over six years; and were, so far as the writer is aware, the first two-cycle gas engines using coke-oven gas. The gas used is that obtained from a battery of Simon-Carvés ovens, and the engines for the most part have used it without any extra cleaning. Experience has shown, however, that an extra cleaning plant could have been installed with many advantages.

The water for cooling is drawn from an adjacent canal, and returned after use, a turbine pump being the circulating agent. These engines are not of recent type, but in general they have worked successfully under the extremely varying load and conditions existing. The use of the current generated is in this case not confined to collieries.

Wharncliffe Silkstone Colliery Power House

At the Wharncliffe colliery the economical advantages of gas-engine driving have been appreciated for many years, and this plant was probably one of the earliest to use the waste gas from coke ovens. Fig. 1 shows a station, which is not the original, but one installed at a later date at this colliery. This plant is of a different type from the preceding one, as the engines drive the generators by means of ropes, thus securing an economy in the capital cost of the generators. The engines shown on the plan consist of a single-cylinder, two-cycle engine, and a twin-cylinder four-cycle engine, both of which operate on the gas obtained from Simon-Carvés ovens. The power generated is led away for use at the surface for air compressing, coal washers and screens, and below ground for hauling, lighting and pumping. The ventilation is at present performed by a steam engine.

Rockingham Colliery Power House

Fig. 2 shows a central power station recently set in operation. It has, up to the present, only one unit, and this is a 600 maximum b.hp. two-cycle engine, driving a direct-current generator. The engine operates on gas of 530 B.t.u. heat value, obtained from Koppers coke ovens, and the current is led away by means of aluminum overhead trunk lines to distant collieries for use in hauling, coal cutting, lighting and pumping.

As an instance of the generation of power by the use of waste fuel in Mason gas producers, mention is made of an all-electric installation at a colliery in South Wales, where the "Bastard" coal, which forms the roof of the seam, is used. By-product recovery is not installed, the gas after being cleaned proceeding to the engines direct. These are of the twin two-cycle type, and are each capable of working up to 800 b.hp. The alternating-current generators of a voltage of 2200, and a frequency of 25, are situated on the crankshaft between the cylinders. A motor-driven centrifugal pumping plant is used for circulating the cooling water. As it is necessary in these producer plants to have the use of a considerable amount of steam, exhaust-heat boilers are fitted to the exhaust of the engine, with the attendant gain in economy. The power from this station is used in the first place for a large haulage engine, then for driving ventilating fans and screens, and for general surface driving. Lighting is provided through a motor-generator, which converts the current to a suitable voltage and provides also for the exciting of the main generators. The fuel used yields a high percentage of ash, and the value of the gas generated is 140 B.t.u. per cu.ft. An effective cleaning plant is necessary, owing to the large amount of tar present in the gas. It has been found advantageous to install a large gasholder, so as to equalize any irregularity in the working of the producer.

I have been connected with the erection of a power plant of a much larger capacity, which has only recently been installed in the Staffordshire district, where the producer plant uses waste fuel with full ammonia recovery.

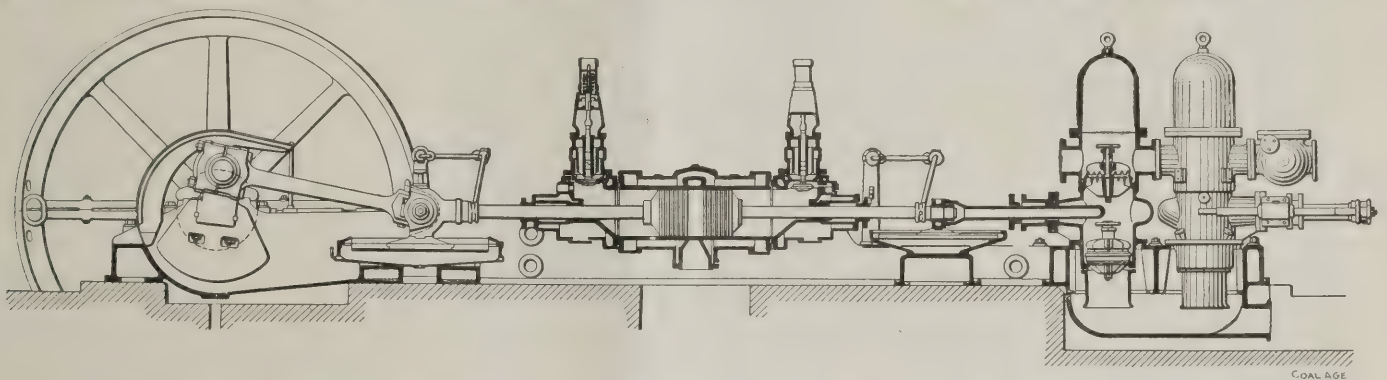

Fig. 3. A Gas-engine-driven Water Pump, Designed for the Hydraulic Operation of a Colliery

The Hydraulic Scheme

This method involves the conversion of the power generated by the gas engine by means of direct-connected pumps working at high pressure. The method was brought to its highest efficiency in Germany. A plant installed at the Herkules pit, near Essen, gave when tested an efficiency of as much as 78 per cent. The high pressure pump on the surface is connected by a main carrying water at high pressure to a special reciprocating water-motor-driven pump in the mine, the discharge being returned to the inlet of the pump at the surface. This system, if intended to perform the various other duties below ground, may be costly both in first charge and upkeep, but its high efficiency is in its favor, and in Germany there are many installations of the kind for pumping only. There is no doubt that this system could be, and perhaps has been, adopted for hauling, etc., and might possibly be applied to hoisting, but with greater difficulty. No installations of this system appear to have been laid down of late years. The hydraulic accumulator offers an excellent method of dealing with peak loads. This system is sometimes used, as in America, to operate water turbines underground. Fig. 3 shows a direct gas engine-driven pump suited to such service.

(To be continued)

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

If the life story of any man engaged in coal mining is calculated to encourage and inspire others to strive for success, then surely the following sketch of Morris Williams, president of the Susquehanna, and all the other coal companies owned by the Pennsylvania Railroad, will accomplish that laudable aim.

Born in Monmouthshire, Wales, in 1855, Mr. Williams was brought to this country by his parents, who emigrated to Pennsylvania while he was still an infant. The family settled in Schuylkill County, and at 13, Morris was attending school in winter and picking slate in a breaker during the remainder of the year.

When 17 years of age, Mr. Williams secured employment underground in one of the near-by collieries, and after serving in the capacity of mule driver, as well as filling other jobs about the pit, he became a full-fledged miner, and dug coal until he was 21 years old.

Having saved a part of his earnings during this period of hard labor, "M. W." went to Millersville, Penn., and attended the normal school for two years, working about the mines during vacation time. At the conclusion of this brief schooling, Morris secured a position on the engineering corps of the Lehigh & Wilkes-Barre Coal Co. near Hazelton, remaining with this latter concern four years.

While thus engaged in mastering the problems of coal engineering, Mr. Williams taught during spare hours, and in addition utilized all available minutes in reading law, it being his ambition at that time to become a lawyer.

The next move he made was to accept an engineering position with Major Stearns, one of the pioneers in the development of anthracite coal. This work provided him much valuable mining experience and occupied three years of his time. This stage of Morris Williams' life is of peculiar interest, as it shows how, "a person who resolves on any great end, has scaled the highest barriers to it." Deprived of a college training, he sought out an educated man (a clergyman by profession and occupation), and tutored under this instructor for three years, completing in that time, solely by night work, the practical equivalent of a university curriculum.

In 1885, Mr. Williams went West and engaged in metal mining, holding the position of superintendent of a gold mine in Wyoming. At the same time he busied himself with geological work in

Morris Williams

Colorado, having become associated with an engineer well versed in geological practice. This training has been of much benefit to him in overcoming many problems in the development of anthracite-coal seams.

Following his sojourn in Wyoming and Colorado, he undertook some special examination work in Texas and Mexico, for the Texas & Pacific R.R. Co. This task completed, he returned to Pennsylvania, accepting a position at Shamokin as engineer for the Mineral Railway & Mining Co., a subsidiary of the Pennsylvania R.R. The year following, 1888, Morris Williams was made superintendent of the last mentioned company, and held this position until the year 1897, when he was made manager of the same concern, succeeding Major Stearns. In 1903, when General I. J. Wister resigned as head of the Pennsylvania R.R.'s combined coal interests, Mr. Williams was made president, and was saddled with the additional responsibility of looking after the selling, as well as the mining end of the business.

Morris Williams differs in one important respect from most men who have tasted the discomforts of hard manual labor—Frequently when an individual rises from the lowliest ranks, he becomes the worst kind of a czar, and seemingly forgets all the bitter happenings and unpleasant moments resulting to him from the autocratic inhuman treatment of petty officials. Not so with Morris, his heart and sympathies are with the fellow who is unfortunate enough to be toiling at the foot of the ladder. You don't have to appear before a notary and make affidavit that you are of sound mind and good character, before you can see the president of the Susquehanna Coal Co. It's this special point that has helped him to the top and endeared him to his subordinates.

After a short acquaintance with Mr. Williams, no doubt remains in your mind as to the one essential that has brought him success. The element in question is "persistence." He has never been known to turn back nor weaken when confronted by adversity. His idea is that persistency of purpose is power. That it creates confidence in others, and that everybody believes in the determined man. When such a person undertakes anything, his battle is half won, because not only himself, but everyone who knows him believes that he will accomplish whatever he sets out to do.

Concerning the question of individual industry, he attributes the greater part of human effort to compulsion from personal need. He would revise the old maxim to read—"Necessity is the mother of *industry,* as well as the mother of invention." His philosophy is that—"Nature masks her own ends in our wants, and this urges us onward over obstacles; that the Creator has concealed highest happiness and greatest good beneath sternest difficulties, and made their attainment conditional upon a struggle for existence."

Governor Tener, of Pennsylvania, recently appointed Mr. Williams to serve on the Pennsylvania Workman's Compensation Commission, and it is certain no more fortunate selection could have been made. The men in the Keystone state who work with their hands, and who have slight opportunity to lay aside a sufficient competence to tide them over difficulties, and provide for their families in case the worst may happen, have a friend in "M. W." who will champion their cause as though it were his very own. He is the type of man in whom reason will always maintain its empire over the mind, but in no case will cold facts so control his actions as to exclude sympathy and callous his heart to the needs of less fortunate humans.

Correspondence suitable for the columns of COAL AGE solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Entered as second-class matter, October 14, 1911, at the post office at New York, New York, under the act of March 3, 1879.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of Coal Age, we will print 7500 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.

This journal has a direct aim—a single purpose—which is to help advance the coal-mining industry. Its creed embodies the dissemination of knowledge and the free interchange of ideas among its readers, all of whom are invited to become regular contributors.

Contents

COAL AGE

The Flying Wedge

The British strike rapidly approaches an end. The opportunity, therefore, presents itself to sum up the teaching of this strike which has dealt such a heavy blow to Great Britain.

The suspension could have been made purely local had the miners of England so wished, but with a mixture of gallantry and brutal unthinking cruelty, the English miners concluded to make it otherwise. There was no need for such a long national strike, lasting as it did very nearly a month, for from the first, the greater part of the English operators were ready to concede a minimum wage.

The Scotch and Welsh operators resisted, and it was to aid them that the English miner refused to work. He prepared to enforce his demands by subjecting workers, many of them poorer and more unfortunate than himself, to the most grinding poverty that the pressure of public opinion and of a ministry dependent on his vote, might be compelled to take favorable action on the whole question. If it had not been for large contributions from the benevolent, and money raised by tax collections from those who were not actually concerned, the dèath rate would have been appalling. As it was, many honest people, too proud to accept succor, have been tortured as a result of the thoughtlessness of those who advocated a national strike.

The stand of the English miners has been described as noble, and indeed it had all the cruel gallantry of war. The Welsh operator was receiving about 85c. per ton more than the English. He was better able, therefore, in all probability, to pay a minimum wage, but he refused to pay it. In fact, it is usually the operator who is making the most money, who is best able to withstand pressure of that character. There was no need for the English miner to hold back from work, and he could have protected the public and subsidized the Welsh and Scotch miners and in the end would have realized a greater success. Instead, he preferred to grind the face of the poor, to pauperize the nation, to jeopardize its independence, when work was to be obtained under conditions against which he had no complaint.

Strange to say, the first men to endeavor to return to work were miners living in the counties where their demands were most strongly resisted. This suspension from labor, therefore, did not help the English miner, and it is easy to show that it did not hurt the operators in Wales or Scotland who refused to make any concessions. The suspension from labor of the English miner did not provide a means whereby the liberal operator might enter and seize the market of his rival. It did not help the Englishman to ward off his foreign competitor. It did not furnish the more generous coal owner a chance to profit by his generosity. It put a common penalty on friendliness, indifference and aggressive hostility.

But nevertheless, denying himself the exercise of his reason, John Bull concluded it was a gallant act because it involved a sacrifice. A certain Frenchman said of the charge at Balaklava, "C'est magnifique mais ce n'est pas la guerre," and the same may be said of the present situation—it was gallant, but it was not war.

In college days we thought the most effective move in football was made with the introduction of the "flying wedge," when the momentum of the whole force on the field flung itself on a weak spot of the opposing line. Its very effectiveness broke it up. Nothing could withstand the fierceness of the attack. Today, the miner adopts another and less effective mode of action. He would hurl his whole broadside against the united front of the operators, and make those who would concede, join battle with those who would not. He works valiantly to organize the employers to oppose labor and seems to find delight in penalizing the man who ventures to give him what he asks for.

There has been much opposition aroused to the existence of trusts and it is certain that they must be annihilated or regulated. So far, little has been done or said against a greater trust than any which has been prosecuted in the courts—a trust, open in its methods and almost entirely unrestrained in its actions. We refer to the labor trust. It has been permitted to exist because, the worker being weak, may be safely allowed some privileges denied to capital, which can so easily intrench, and because no human interest can well transcend the living needs of the working classes.

But there is a limit to the combinations of labor, and we think that limit approaches when it combines to refuse the offer of work made by those who concede its demands, when in order to show its strong, unrelenting power, and to paralyze the government, it combines to cease work. A combine to raise wages may be endured and condoned, but a combine to suppress the output when no stock is on hand and when the people must starve without the product, can hardly be described with a more fitting word than crime.

Did any trust ever refuse to sell the output of its mills or mines till *everyone* consented to pay its price, thus bringing ruin on those who were willing to meet its demands as well as on those who were not willing? Has it not been the practice of every great corporation, no matter how arrogant, to sell at any time to anybody who was willing and able to meet its stipulated schedule of charges?

The labor leaders would do well to conclude that their tactics are a violation of national and state laws, and of the absolute rights of the public, and to remember that the courts and people have long winked at labor combinations and pretended to find a distinction in principle where none really existed.

The judicial and legislative bodies have in this matter always had an eye to the defendant and decided that it was not well to compel him to observe a nice adherence to laws of unrestricted commerce because the defendant had too large an interest at stake to be rudely forgotten in the case at issue. But in a matter of paramount importance like that raised by the Britannic strike, if labor will not listen to reason, it must be made to pay heed to law.

Clearly the recent British strike was political, an attack not on the operators directly, but on them through the parliament of Great Britain. As such, it was not merely a restraint of trade—it was an act of treason. As evidence that the purpose was political, we would call attention to the fact that strikes to influence the government have been frequent across the narrow waters of the English channel.

To the great credit of the English workman be it said, however, that he preferred a passive resistance to wanton acts of "sabotage." But it must ever be remembered that Vandal acts of destruction are not so costly as acts of restriction and repression which silently but surely impoverish employer and employee, and bring the proudest people to a condition of mediocrity.

The Industrial Treadmill

We have scarcely yet learned that supply and demand do not regulate wages any more than they regulate the partition of Asian and African lands among the excessive populations of Europe. Wages are determined no longer by economic conditions; in fact, few things salable are any more so determined, both labor and material being controlled by trusts. Consequently there is often no fluctuation in the market prices to correspond with the changes in economic needs and prices for labor usually continue unaltered in an industry until a strike, realized or threatened, makes revision of labor prices necessary.

Such a revision is frequently the result of a change in the cost of the materials which the workingman has to purchase for his daily sustenance. But these materials usually cost more because some other workman has demanded a larger wage for the making or moving of them. So the relation of cause and effect is far-reaching, and frequently back of a needed reconstruction is a rise in the wages of some other artificer.

Thus every strike in an industry involves disorganization in another. Eventually all other industries emerge from the distressing experience with higher wages and an increased cost of product, be that product an actual material or its mere transportation. The cost of living is raised, and a new rearrangement must be made if the workers in the first industry are not to suffer.

Of course other considerations exist—trusts control charges for material, supplies of raw material dwindle or become larger from railroad extension, exploration and development, the stocks of gold vary and the volume of business transacted ebbs and flows. There are many variants, but the wage differential largely changes with these and is the most fluctuating factor of them all. If wages are only to be adjusted by strikes, then contests between labor and capital will frequently recur. A strike holds out an excellent prospect of reward, because the workingman who gets a substantial rise makes his fellow workmen pay more for his product while paying no more for theirs, and the way to succeed is to be learned from David Harum, "Do unto the other fellow as he would do unto you and do it first." The victory is not to the laggard or the unprotected.

Clearly all this is wrong, as bad for business as it is for the workingman. He is placed in an industrial treadmill. He lifts his foot to raise himself, the wheel of prices turns and he is promptly *in statu quo*. If the taking of the step were invigorating exercise, if it made him a happier man, it would be well. But the advance he makes on the treadwheel of industrial progress is taken in rancor and malice and followed by despair. It would be far better for all concerned if prices remained more uniform and wages rose less often, and it is certain that the workingman should receive automatically an increase of wage, proportional to any increase in living cost. If this could be arranged, strikes would be less frequent and when they occurred, would not have the popular appeal they now have.

When, under the present *régime,* a change of wages takes place, it is usually an arbitrary concession bearing reference to the change in prices in sign but not in quantity. Thus wages are raised inordinately and as such raises affect all skilled industries one by one, the cost of living becomes unduly advanced, and another violent labor readjustment is needed. That readjustment would possibly not have been necessary and would certainly have been less disturbing had the initial concessions been figured on a scientific basis.

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Strong Roof and a Narrow Working

In answer to T. E. Richard's question on page 685, Mar. 2, I would say that controlling a mine squeeze is a difficult matter even under the most favorable circumstances. I would advise the driving of the last three rooms on the cross-entry to their limit, and the discontinuance of work on the parallel entry. I would then draw back the ribs of the three cross-entry rooms thus extended and at the same time the ribs of the last three rooms in the parallel entry.

I would then draw back the heading stumps and chain pillar as far as the mouth of the third room, taking care that no coal is left in any of the pillars, and that all props or posts are removed as far back as the retreating work is completed. What is wanted is that a sufficient area be taken out to cause a break. After that is secured all trouble is over. Crossbars will not prevent a squeeze nor will any other timbering. The weight will ride over all such supports until a break occurs. The line along which the pillars are worked is that of the best usage but the order followed in extending the rooms of the cross-entry is contrary to good practice. The rooms nearest the old mine should be started first, and the others progressively opened as occasion demands toward the main entry or flat. The line of fracture in the cross-entry should be maintained the same as in the parallel heading.

Sealing Off Mine Fire in a Gassy Mine

I wish to state I have read with considerable interest the different letters submitted *re* the proper method of sealing off a mine fire that has gotten beyond control, rendering it practically impossible to fight it by the direct method. I have had considerable experience in fighting mine fires in gaseous mines, and have always advised the building of the first stopping on the return side. Although I am aware that this is practically impossible to do in some cases where conditions are adverse, yet I consider it well worth the effort if possible at all.

I have never experienced any explosion so far when the stoppings were built in this way. By closing the return side first, the products of combustion generated by the fire, which are principally extinctive gases, are confined to the region of the fire, enveloping it in a cloud of gases that are capable of rendering inexplosive the otherwise explosive gases that accumulate behind the stoppings, owing to the air being gradually cut off during their construction.

Moreover, the confined gases expanded by the heat of the fire will force back the fresh air and gases onto the intake, and eliminate the possibility of sealing up a large amount of fresh air and gas with the fire. I assume this is a gaseous mine; and unless the first stopping is built on the return side of the fire, these conditions are liable to cause a disastrous explosion.

I had the experience some years ago of seeing a stopping put in on the intake side first, in a very gaseous mine. The result was that, when the stopping was about three-fourths completed, there was a strong explosion, which blew down doors in the mine, and would, no doubt, have resulted in the death of the men engaged in building the stopping had it not been for the recoil that occurred at the downcast of the affected districts. This downcast, or air-and-water chute, was located about 2000 ft. beyond where the stopping was being built, and was very wet, as it was used to convey the ditch water of the upper workings that had been worked out, to the entry below, where it was pumped to the surface. The explosion recoiled at this point, owing to the reduction in temperature of the flame as it passed through the water chute, which was about 300 ft. long.

Timbering a Mine Parting

I note in COAL AGE, March 23, p. 786, a question suggested for discussion by Noah Burton, Anglin, Ky., on the Best Method of Timbering a Mine Parting. Under the conditions named by Mr. Burton, I would suggest that no timber whatever be used as supports; and instead would advise the use of steel girders placed, say 18 in. apart, their ends being supported by walls of reinforced concrete of suitable thickness on either side of the parting. Old discarded mine rails cut in suitable lengths should be placed over the girders for lagging and any open space above these rails should be filled with débris. By adopting this plan of securing a mine parting the work is permanent and if properly executed will last for years. Then, again, if the job is worth doing at all, it is worth doing well.

Mine fires incident to heavily timbered partings are avoided, as is also the great risk of wrecked cars knocking out timbers and causing serious accidents and delays.

Thawing by Electricity

Referring to the question of thawing a frozen pipe line by means of a current of electricity, as mentioned on p. 586, COAL AGE, Feb. 10, and further discussed by Thomas Brennan, p. 785, Mar. 23, would say I have used electricity for thawing frozen pipes and believe it to be the quickest and cheapest means that can be employed. With direct current all that is needed is a source of supply consisting of a heavy power cable. To this attach a short length of a similar heavy cable, at the end of which is a bar of iron so arranged that it can be raised or lowered in a barrel of brine. At the bottom of the barrel is another bar of iron attached to the end of a heavy cable that serves to connect this bar with one end of the frozen section of pipe. The other end of the frozen section must have a return wire or be sufficiently grounded to insure a good current passing through the frozen section when the current is turned on.

The current-carrying capacity of the pipe must be less than that of the cable and the other wires in the circuit, so that the pipe will act as a resistance and become heated by the passing of the current. Practically, the heating effect of the current in the pipe line is regulated by raising or lowering the bar of iron suspended in the barrel of brine. The brine, in this case, acts as a water resistance and controls the strength of the current and, incidentally, the heating of the pipe. I have seen a half mile of frozen pipe thawed in five minutes, by this means. In *Engineering News* for Mar. 17, 1904, p. 251, are given data and description of an electric thawing apparatus used by several cities and towns.

Reducing Ventilation when Firing

With regard to R. Z. Virgin's remarks in Coal Age, March 30, page 817, I would say that mining practice and measures for the protection of life, not of general application, must be determined in accordance with local conditions and requirements; and it may develop that a practice considered dangerous in Pennsylvania is a permissible and reasonably safe undertaking in Iowa. The Iowa mines do not generate explosive gas. The shots are fired after the miners have left the mine. The fan is slowed down while the shotfirers are at work and, at new mines, it is frequently stopped entirely. This practice has been in general use for the last ten years, surely a long enough test to bring out any drawbacks or dangerous consequences due to its use. So far, evidence showing the practice to be in any way unsafe has not been developed; while, on the other hand, satisfactory proof of its possible merits and benefits has been established and the practice has now the general approval of the operators, the miners and the shotfirers.

No claim was ever made that slowing down the fan at firing time would stop the occurrence of explosions entirely; but I have suggested the plan and adopted it as a fair makeshift and palliative to minimize the effect of an explosion, should one occur. Judging from the results, it appears that Iowa practice has proved at least as effective in this respect as sprinkling and spraying the dust. What few explosions have occurred in Iowa mines, in the last ten years, have shown comparatively little violence and were of small extent.

It should be understood that dust explosions, in their incipiency as well as in their propagation stage, can receive the necessary supply of air, under favorable conditions, without the aid of an artificially induced draft. In the absence of such favorable conditions, however, the inception of such an explosion depends largely on the assistance of a forced draft; and it is, therefore, evident that in all such cases the velocity of the air as determined by the speed of the ventilator becomes the controlling factor. This is not an opinion but a fact proved by the experiments of Mallard and LeChatelier that the velocity of the air current carrying the dust in suspension has a great influence on the degree of inflammability of the dust.

Mr. Virgin says: "I am of the opinion that slowing the fan increases the danger incident to firing shots." The facts, however, appear to sustain the opposite view. In experiment No. 11 at Altofts, the charge of dust was 400 pounds; in experiment No. 13 the charge of dust was 324 pounds, 76 pounds less. The charge of powder was the same in each case as were also the position of the cannon and the surrounding visible conditions were also identical. There was, however, a marked difference in the velocity of the air. In experiment No. 11 the recorded velocity was 655 ft. per min., while in experiment No. 13 it was 1219 ft. per min. Experiment No. 11 produced a rather mild explosion, doing no particular damage, while experiment No. 13, with a lesser charge of dust resulted in a most violent explosion, destroying part of the gallery, tearing up 43 ft. of the concrete floor and hurling the heavy valve, No. 9, a distance of 426 ft. If the difference in the velocity of the air was not the main cause of the discrepancy in results, what was the factor that brought it about? It will not do to say it just happened that way; for the results of explosions depend on and are determined by surrounding conditions. Like conditions should produce like effects. In the public tests made at the Pittsburg experimental station the results of these tests, which were repetitions of previous experiments, could have been accurately foretold, by those in charge, before the shot was fired in the gallery.

I believe in thorough and efficient ventilation of all mines, but I am not unqualifiedly, like Mr. Virgin, "a strong advocate of fresh air; the more the better, within reason." That has been the slogan of the English miner; for generations he was taught that the presence of a strong current of pure air meant added protection to him, at all times and under all conditions; and by his acts he has shown his implicit belief, even up to the present time, that a mine opening swept by a brisk air current was immune from explosions of any kind. Hundreds of lives have been lost through this mistaken belief, a fact supported by the statement in bulletin No. 425, of the Bureau of Mines, to the effect that "firing shots on the roadways (the reports show they were briskly ventilated when the firing was done) has been a frequent source of disaster in England." For example, the Altofts explosion in 1886, causing the death of 22 men and boys, took place on the principal intake airway 500 yd. from the downcast shaft. Along this airway a current of 40,000 cu.ft. of air per min. was passing. The Elemore explosion in which 28 lives were lost the same year, occurred on the principal intake airway 200 yd. from the downcast shaft. The amount of air passing through this airway was 37,800 cu.ft. per min.

Such instances should serve as a lesson and a warning that the evident beneficial effects of good mine ventilation should not be permitted to obscure the fact that a strong, fresh air current in a mine, although necessary and desirable, may be readily converted into a highly potential agency of destruction.

Chariton, Ia.

Timbering a Mine Parting

In answer to the question asked by Noah Burton, in regard to the best method of timbering a mine parting, Coal Age, March 23, page 786, would say, my plan would be to cut into the coal on both sides of the track so that the legs of the timber frames can be set back in the rib, clear of the track, where they cannot be knocked out in case a car jumps the rail. The headers (crossbars) should then be set close to the roof. This is always a safe system to adopt in timbering partings, because a car cannot trip the timbers in case of a derailment or wreck. Such an accident has often caused the life of a man or a mule.

In case the roof stratum is soft and not very thick, it will generally pay better to take down the soft top to the solid. This work should always be in charge of an experienced mine boss, or timberman who understands the proper method of taking down roofs and timbering.

Red Ash, Va. A. T. Wade.

The Cambria Coal Field in Wyoming

The article by Mr. Simmons under the above title which appears in issue of Coal Age of March 23, 1912, faithfully describes the principal features of the district and the mining conditions and peculiarities of the coal at Cambria, Wyoming.

Mr. Simmons is justified in giving much credit to the enterprise and energy of Kilpatrick Bros. & Collins in opening up and developing the field, for they deserve this credit and whatever profit they have been able to make in operating the property and in disposing of it to the present operating company.

Early Work of the Burlington

To those familiar with the conditions preceding and attending the development of this coal field, it will seem only right, however, that the matter should not be passed over without mention of the part played by Mr. Perkins, former president of the Chicago, Burlington and Quincy Railroad, and by Mr. George A. Holdredge, Manager of the Burlington and Missouri River Railroad which operated the C. B. & Q. lines West of the Missouri River; for it was only through the farsighted wisdom of these gentlemen, and of the Board of Directors of the C. B. & Q. R.R., that the development of this district was accomplished.

During the '80s, when the Burlington and other railroads were building feeders and spurs through the Dakotas, Nebraska and Kansas, gridironing the arable portion of those states with lines of rails, the fuel question began to loom up as one of serious import. This ap-

plied not only to the railways for steaming purposes, but to the rapidly growing population which followed the railroad extensions.

About 1885 the Burlington management began to canvass actively the country tributary to its lines for a suitable fuel supply, and extensive examinations were made of coal in Colorado and elsewhere. But the regions promising coal of suitable quality were not easily accessible and could not be reached except at large cost, involving the building and operation of many miles of railroad with heavy grades, and at high altitudes.

From the outset it had been the policy of the Burlington to confine its activities to those of a common carrier, and not to engage directly or indirectly in coal mining or other industries. But it had also definitely adopted a policy of encouraging the development of local industries, and this, together with its own pressing requirements for a fuel supply from mines on its own lines, naturally led to an arrangement, made some years later, whereby Kilpatrick Bros. & Collins agreed to supply the company with fuel from the mines at Cambria.

The First Explorations

In 1887, Kilpatrick Bros. & Collins, who as contractors, had built many miles of railroad for the Burlington, and who had earned the confidence of the Burlington officials, had their attention drawn to this region. Having determined to spend some money in trying to develop a workable coal they commenced at once to drive a drift in a seam about 4 ft. thick, which was parted at the center by a bed of hard sandstone about one and a half to two feet thick. About this time Mr. Perkins, at the suggestion of Mr. Holdrege, decided to have the whole region explored to learn whether there was any possibility of securing a railroad fuel supply from it, and doing nothing by halves, he decided to extend this exploration from the Black Hills on the Dakota-Wyoming line, westwardly across Wyoming to the Big Horn Mountains. It was of course already known that this was a region of great lignite and lignitic coal deposits, in which beds of great thickness extended over a very large area, but it was not known whether, in addition to the lignites, there might not be some areas or some beds which would yield coal suitable for railway fuel.

I was engaged by the Burlington, to make this exploration, and to advise Kilpatrick Bros. & Collins in the development of the Black Hills region, or other localities where I might advise them to do development work, and I made the first examination in the fall or early winter of 1887. At that time the coal at Cambria was unknown, and the coal at the opening above described being unworkable, I advised them to explore the canons cutting the plateau to the north and east, at the same geological horizon, to see whether an area could not be found in which the coal was workable. A camp was accordingly established and the work entrusted to Mr. Frank Mondell, then an employee of Kilpatrick Bros. & Collins. In this work Mr. Mondell demonstrated the ability which in later years has caused his election and re-election to represent this district in Congress.

Congressman Mondell—Prospector

Mr. Mondell's work resulted in the discovery of the coal where it is now worked at Cambria. His work was at first greatly hampered because along the outcrop and often for a distance of 30 to 100 ft. under cover the coal had been burnt, and the search for coal smut became a search for coal ashes.

Before this condition was discovered and recognized, the exploratory work was most discouraging, long distances along the place where the outcrop should have been found showing no traces of coal, or coal smut, until we learned to look for ashes and not for a coal smut.

Under Mr. Mondell's management, during the summer of 1888, a considerable area of workable coal was proven by drifts driven in on the outcrop in the canons, and by diamond drill holes bored from the surface of the plateau. I was able to report to the Burlington officials that there was practically proven or assured by this work some 12,000,000 tons (if my memory is not at fault) of workable coal of a quality suitable for locomotive use.

The incidents leading up to and following the development of this operation furnish a most interesting example of the part often played by railway corporations and the officials of such corporations, in the opening up of our country to settlement and of the development of its resources. History has since demonstrated the wisdom of the officials of the Burlington in this, and in other directions, as evidenced by the subsequent large enhancement in the value of its securities, and the cordial relations which always have existed between it and the communities which the railroad serves.

I heartily agree with Mr. Simmons' eulogy of Kilpatrick Brothers and Collins and cordially endorse his tribute to their energy and enterprise and to their record as whole souled fellows who never do anything without doing it well. But I think it would be a grave injustice to the officials of the Burlington to permit this matter to pass into history without recording the part played by them in the development of this coal field, and other enterprises in districts tributary to the lines of that company.

H. M. Chance,
Consulting Engineer.
Philadelphia, Penn.

A Successful Type of Rotary Dump

Referring to the article by Mr. Lindrooth, "A Successful Type of Rotary Dump," in Coal Age of Mar. 16, I wish to call attention to the fact that the idea of this dump had its origin in the fertile brain of the late Richard Ramsey, of Braceville, Ill., the inventor of the first box-car loader. His dump was double, the empty car being returned to position by the next load. This dispensed with the back balance, but required a deeper hopper for clearance and caused some breakage of the coal.

In 1897, with Mr. Ramsey's permission, I used his idea in perfecting a dump like the one shown in your paper, and installed three of them for coal and rock cars at our No. 3 mine, in 1898. They remained in service until the mine was abandoned in 1909. Again, in 1904, two more were installed at our No. 6 mine, and are in use today, handling the output of coal and rock successfully. They are the simplest cross-over dumps in use, and in no case have they cost us a dollar for repairs.

We adopted the closed-end car with this dump in 1898. We also adopted the practice of forcing the mine-car wheels onto the axles and thus got rid of the two abominations on pit cars, loose doors and loose wheels, at the same time.

W. Harkes,
General Superintendent, Big Four Wilmington Coal Co., Coal City, Ill.

Preparing Shot Holes

With reference to the question of securing maximum efficiency in firing permissible powders, I desire to say that the charging density and disruptive effects of permissible explosive cartridges may be greatly increased, when the cartridge is smaller in diameter than the drill hole, by slitting them lengthwise and tamping tightly into the holes. Air spacing will give slow action. This is done by placing a plug of tough, soft clay between the explosive and the stemming, and when doing this great care must be taken to tamp firmly the remainder of the stemming. This practice reduces the charging density and the explosive force may be regulated to suit the coal being blasted. Wooden rods which fit snugly into the drill holes should always be used for tamping bars. Tamp the stemming loosely near the explosive and tightly for rest of hole.

Pittsburg, Penn. A. M. C.

Colliery Notes and Comments

Practical hints gathered here and there, and condensed to suit the busy reader

During the year 1910 Nova Scotia shipped $368,146 worth of coal to the United States.

A 3-in. layer of portland cement mortar applied on expanded metal lathe is a good protection for coal bins.

The transmitting lines of electrically driven fans should be independent of trolley lines so that any trouble with the trolley system will not interfere with the ventilation.

Good air-tight stoppings, costing about one-third as much as brick stoppings, may be constructed of "Burkett' lath, plastered with wood fiber, mixed with an equal quantity of sand.

In designing a pumping plant for a mine the capacity of the pump should be 2½ times the amount of water to be handled. The sump of such a plant should accommodate an accumulation of from 36 to 48 hours.

Adjustable loading-booms for loading railroad cars at the breaker are a great factor in the elimination of breakage. When an empty car is being filled the boom is close to the bottom and rises gradually as the car fills.

Experiments have shown, that within certain limits, the strength of mine props is independent of their length. A fairly straight, medium-length prop should be able to withstand a pressure of one ton per square inch of small-end area before crushing.

Wooden mine cars should have their sides and ends built of tongued and grooved boards to prevent the dropping of dust on the roadways. The bottom should be lined with sheet iron for the same reason and this prevents damage while loading; furthermore, it also greatly facilitates dumping, as the coal slides easily from the sheet-iron surface.

The Prussian Firedamp Commission has estimated that from 10 to 13 ft. of flame result from a blownout shot of half a pound of gunpowder in a non-gaseous atmosphere when the hole is stemmed with clay. Where stone and coal dust are used for stemming the flame increases to 16 ft. A pure coal dust stemming results in a flame from 31 to 52 ft. long.

In the coal mines of Durham and Northumberland, England, chambers are not arbitrarily awarded the miners, but they are allowed to draw lots for the same, which gives every man an equal chance of securing the best chamber, thus safeguarding the men's rights. These drawings take place every three months. Each district or colliery adopts rules for the drawing suitable to local conditions.

For fighting fires in the pitching breasts of the anthracite mines, elecric fire-fighting cars are sometimes used. They consist of a truck equipped with an electric pump, hose, insulated wire, fire-extinguishers, axes, saw, hatchet and a first aid supply-box. These cars can be run to any point in the mine which is tracked and a stream of water, drawn from the mine ditch, directed against the fire within a short space of time.

According to the *Engineering and Mining Journal,* the comparative fuel cost at the Port Henry, N. Y., power plant is as follows: 11 tons of No. 2 buckwheat (anthracite) worth $2.65 per ton at the plant, is equal in heating value to 10 tons of bituminous, at $3.92 per ton, or $29.15 worth of anthracite equals $39.20 worth of bituminous coal, thus making the cost of operating with bituminous 1.345 times more than for anthracite.

Some European methods of testing mine ventilation are: (1) The Liveling principle, based on the fact that platinum burns with a brighter glow when CH_4 is present than it does in pure air. (2) The Shaw method, which consists of adding pure CH_4 to a mixture until the explosive point is reached; the difference between the amount added and the amount necessary to produce an explosion is the amount of gas held in the ventilating current.

In working thick seams of coal with several partings the question of impurities in the coal is of great importance. Where the partings are thick, and the coal mined by machine, the amount of impurities may be reduced to a minimum, but where the partings are thin, and the coal shot from the solid, the presence of more or less bone and slate in the mined coal is unavoidable. When a large output has to be handled by one tipple, it is best to remove as much as possible of the impurities at the working face, because the dumping must be done too quickly to permit much inspection.

To fix pencil lines on drawings, rub the drawing with a piece of wax like that used in the manufacture of phonographic rolls. This produces a kind of varnish which protects the lines against rubbing and insures their preservation. Paper as well as tracing cloth can be protected in this manner. Another method is to heat the paper slightly before using it, then spread a solution of warm alcohol and bleached colophone rapidly over the surface so as to thoroughly wet it, after which it is to be dried in warm air. The pencil works easily on the surface of paper so prepared. In order to fix the lines, it is merely necessary to reheat the paper slightly for a few moments. The lines are then covered with a thin coating of transparent varnish, which preserves them in perfect clearness.

To clear firedamp from mine workings provide a liberal volume of air properly conducted to the working faces. Where poor ventilation has allowed a large body of gas to accumulate it should be removed gradually, in sections, as by this method the gas is more easily broken up and the return current does not become so gaseous as when the air current is turned into the whole body of gas. While this is being done withdraw all men from the dangerous parts of the mine and the return side of the gas body. See that only careful, competent men, supplied with a good type of locked safety lamp are employed in the work. Take good care to fix all brattices or air pipes on the intake side and to keep all safety lamps away from the accumulation of gas near the floor. Provide an abundant supply of timber, brattices, lathes, nails and pipes.

The conditions which wiring systems have to withstand in mining work are peculiar and often severe. Everything used in a mine must be designed to endure rough and unskilled handling, and of a nature capable of resisting corrosive and abundant pit water. Sparking must be avoided, or at least confined. Efficient grounding is not easy to effect. Wall and roof movements occur. Extensions of electrical wiring are of almost weekly occurrence, and these have often to be carried out quickly and in a bad light. Dangers from shock are increased, owing to confined space and to working conditions which lower the electrical and vital resistances of the workers. When these special conditions are not studied in design, D. S. Munro is correct in assuming that electricity, which ought to be the safest carrier of power and light, may be actually more dangerous, and, because of unfamiliarity, more dreaded than older methods.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Interesting Questions Selected from Various Recent Examinations

Capacity of Pump To Drain Shaft

Ques.—In the course of sinking a shaft, a feeder of water was met when a porous sandstone was struck. The water rose 300 ft. in the shaft. A pump having a capacity of 300 gal. per min. failed to lower the water more than 62 ft. What would be the capacity of a pump capable of draining this shaft?

Ans.—Assuming that the height to which the water rose in the shaft (300 ft.) represents the natural head of the feeder in the strata, and that the flow increases as the water level is lowered in the shaft, in proportion to the square root of the effective head, we have the ratio of the flow, in gallons per minute, is equal to the square root of the ratio of the corresponding head, in feet.

Therefore, if the flow is 300 gal. per min. under a head of 62 ft. the question is what would be the quantity of the flow for a head of 300 ft., or when the shaft was completely drained. To be safe, call this head 310 ft., which gives round figures. Then, calling the required capacity of the pump, for this head, x,

$$\frac{x}{300} = \sqrt{\frac{310}{62}} = \sqrt{5}$$

$$x = 300\sqrt{5} = 670 + \textit{gal. per min.}$$

Horsepower Required to Hoist Coal

Ques.—What horsepower will be required to hoist 1200 tons of coal up a shaft 525 ft. deep, in 8 hr., allowing 12.5 per cent. for the resistance of rope, pulleys, etc.

Ans.—Adding 12.5 per cent. or ⅛ of the load hoisted to allow for friction the load including friction is

$$1200 + \frac{1200}{8} = 1350 \textit{ tons}$$

Practically, a certain time should be allowed for unavoidable delays, say 5 per cent., making the actual time of hoisting $8 \times 0.95 = 7.6$ hr. each day. But, since it is necessary to calculate the horsepower on the maximum speed in hoisting, and since about one-half the actual time of hoisting is lost in dumping or changing cars between trips and starting and stopping trips, the time of hoisting the full depth of the shaft at such speed might be taken approximately, in this case, as

$$\frac{7.6 \times 60}{2} = 228 \textit{ min.}$$

To do this would require

$$H = \frac{1350 \times 2000 \times 525}{228 \times 33{,}000} = 188 + hp.$$

[The theoretical horsepower, making only the given allowance for friction, and not allowing for loss of time, in delays, changing cars and starting and stopping trips would fall short in actual practice. This theoretical power would be

$$H = \frac{1350 \times 2000 \times 525}{8 \times 60 \times 33{,}000} = 89.5 \; hp.$$

In actual practice more data are required to make this calculation with accuracy, in order to determine the load per hoist and the necessary maximum speed of hoisting. In the above we have assumed a balanced hoist and ignored the weight of the rope hanging in the shaft.]

Discharge of Siphon

Ques.—In a siphon pipe line 4 in. in diameter and 1760 ft. long, the greatest altitude of the pipe is 15 ft. above the intake end and 52 ft. above the discharge end. How many gallons of water will this siphon discharge in 1 hr.?

Ans.—The lengths of the two arms of the siphon are not given, but only the total length of the pipe. Therefore, assuming that these respective lengths are such that the intake end, under atmospheric pressure, will supply the discharge end, which flows under gravity, the quantity of water discharged per hour will be

$$G = 60 \times 4^2 \sqrt{\frac{52 - 15}{\frac{1760}{800 \times 4} + 0.0026}}$$

$$= 7852 + \textit{gal.}$$

Pressure Due to Blasting

Ques.—Give the pressure per square inch on the tamping when 6 lb. of F F powder is exploded in a 3-in. drill hole, in blasting coal.

Ans.—Black blasting powder yields on explosion 360 times its volume of gases, measured at 32° F., barometer 29.92 in. and a solid residue of ⅓ the volume of the powder exploded. When the powder is exploded in a drill hole or other confined space the 360 volumes of gases are crowded into a space that is ⅔ of the original volume of the powder, owing to the solid residue that fills the remaining ⅓ of the original space occupied by the powder. This is equivalent to

$$360 \times \frac{3}{2} = 480 \textit{ volumes}$$

of gas filling the entire space occupied by the powder, or 480 times the volume of the powder; and increases the pressure 480 times the original pressure, which was 14.7 lb. per sq.in.

The pressure at the moment of explosion, however, is very much increased by the rise of temperature due to the combustion of the powder. The theoretical temperature due to the explosion of black blasting powder is 3600° F.; but to obtain this high temperature the combustion must be complete in an instant of time, which is not the case. Black powder burns at a comparatively slow rate, depending on the size of the grain and quality and hardness of the powder. Much of the heat developed is radiated and lost before the combustion is complete. On this account, the temperature in the drill hole, in blasting coal, rarely exceeds 2000° F., in good practice.

This makes the pressure due to the explosion of black blasting powder, in a drill hole, at sea level,

$$\frac{14.7 \times 480}{2000} \times \frac{460 + 2000}{460 + 32} =$$

$$\frac{14.7 \times 480 \times 2460}{492 \times 2000} = 17.64 \textit{ tons per sq.in.}$$

The question asks for the pressure per square inch exerted on the tamping by the explosion of a given weight of powder. The pressure per square inch does not depend on the weight of powder exploded or the size of the hole. It varies with the elevation above sea level.

Pumping Calculation

Ques.—(a) What is the cylinder displacement and theoretical discharge of a pump whose water cylinder is 12 in. in diameter and length of stroke 16 in. when making 90 strokes per min.? (b) Assuming an efficiency of 85 per cent. for the water end of this pump, what is the actual discharge?

Ans.—(a) The piston speed in this case is

$$S = \frac{16 \times 90}{12} = 120 \textit{ ft. per min.}$$

Piston displacement,

$$120\left(\frac{0.7854 \times 12^2}{144}\right) = 94.248 \textit{ cu.ft. per min}$$

Theoretical discharge,

$$\frac{94.248 \times 1728}{231} = 705 \textit{ gal. per min}$$

(b) Actual discharge,

$$G = \frac{705}{0.85} = 828 \textit{ gal. per min.}$$

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

The proposed repeal of the Canadian reciprocity act, which has been urged by the Senate committee on finance, in a report rendered within the past few days, is being opposed by President Taft, who expresses the hope and belief that it may still be possible to obtain an adjustment with Canada later on, when that country has had time to reconsider the question of closer trade relations with the United States.

One of the items, in regard to which it is especially desired that there shall be no change so far as the act is concerned, is that embracing coal and slack. For these commodities, a substantial reduction had been arranged in the bill, which was rejected at the polls in Canada last autumn. It is the opinion of the President's advisers that these items are particularly likely to serve as a useful basis for negotiations in the future, and that to repeal the bill now would leave the President without the possibility of authority to include them in a treaty with Canada, should conditions later favor such action.

It is said that in all probability the Ways and Means committee at the next Congress, if the Democrats continue in power, will report a bill in which the President will be given authority to negotiate treaties of reciprocity with foreign countries on a distinctly lower basis of rates than that which prevails in the general tariff, and it is understood that coal will be one of the items on which the Democrats will establish the lower schedule of rates which is to be offered in the proposed bill. It is believed that a large trade in coal may be developed with the aid of the Panama Canal if conditions are made moderately favorable, by securing the abolition of duties in foreign countries through holding out of sufficient inducements in the way of reductions of duty on articles imported into the United States.

Coal Strike Legislation

A general understanding has been reached apparently, to the effect that in the absence of any new and more threatening developments in connection with the impending coal strike, there probably will be no further action taken with respect to the Lee and Townsend bills, providing for an extension of the Erdman act to apply to strikes in the coal industry. Neither does it at present seem likely that any substitute provisions of like character will be taken up. The bills will be left in committee.

If any step of the sort is taken at this session of Congress, it will probably be the reporting and possible passage of a modified form of the Foster bill to create a Commission on Mining Industry. This bill provides that a commission shall be created as follows:

Said commission shall be composed of 11 persons, to be appointed as follows: Two members of the Senate (including the chairman of the Committee on Mines and Mining and one member to be appointed by the President of the Senate), two members of the House of Representatives (including the chairman of the Committee on Mines and Mining and one member to be appointed by the Speaker of the House), two representatives of mine operators, two representatives of miners, two mining engineers and one representative of the Bureau of Mines, to be appointed by the President of the United States.

Duties of the Commission

The portion of the bill which applies especially to the coal industry is as follows:

The commission shall inquire into the general condition of labor employed in the mining industry of the United States, and especially as to the safety of mining and the methods of more efficient mining and the conservation of the mineral products of the United States; into existing relations between employers and employees; into the growth of associations of employers and of wage earners and the effect of such associations upon the relations between employers and employees; into any methods which have been tried in any state or in foreign countries for maintaining mutually satisfactory relations between employees and employers; into methods for avoiding or adjusting labor disputes through peaceful and conciliatory mediation and negotiations; and into the scope and methods and resources of existing bureaus of labor and of mines and into possible ways of increasing their usefulness so far as the mining industry is concerned. The commission shall seek to discover and to point out the underlying causes of dissatisfaction in the mining situation.

Alabama

Birmingham—It has been announced that the Sloss-Sheffield Steel & Iron Co. has agreed to pay the State of Alabama 45c. per ton for coal mined by the convicts employed by the company. This is an increase of 2½c. per ton over the terms of the original contract. The agreement between Gov. O'Neal and officials of the Sloss-Sheffield company was reached only after several conferences on the subject had been held.

Corey—The Tennessee Coal, Iron & Railroad Co. has fired the second battery of its new Koppers byproduct coke-oven plant. This battery of 70 ovens marks the completion of one-half of the large plant now under construction. It is expected that the two remaining batteries and the balance of the plant will be finished by June 1 of this year.

Colorado

Trinidad—After a conference of coal operators of Las Animas, Huerfano and Fremont Counties, the mine employees were allowed a substantial increase in wages, taking effect Apr. 1. Miners will receive an increase of 5c. per ton, run-of-mine, and all other classes of labor will receive a corresponding increase. More than 12,000 men are affected by the increase and these are scattered among the 100 mines at present in operation in the district. The operating companies have decided to increase the price of coal 10c. per ton, so the consumer, and not the companies, will really have to pay the advance. The Colorado Fuel & Iron and the Victor-American Fuel companies took the initiative in the movement. The other companies which agreed to the increase are the Rocky Mountain Fuel Co., the National Fuel Co. and the Consolidated Coal & Coke Co. Small Independent operators are expected to follow the action of the big companies.

Illinois

Peoria—The Peoria District Collieries Co. and the Western Coal Sales Co., two local concerns, were recently incorporated for the purpose of mining and selling coal. The present capitalization of these companies is small, but it is understood their capital will be considerably increased later. The Collieries company will operate the Scholl mines at Bartonville.

Streator—All the properties of the Star Coal Co., of Streator, have passed into the hands of a new company, to be known as the Star Coal Co. of Galesburg. The new company is capitalized at $51,000 with Thomas Fairbain as president. The properties include three mines at Cuba, ordinarily employing about 400 men, and one mine at Fiatt, which has been closed since Dec. 1. The Fairbain

interests own other coal operations in this locality. All the properties lie along the Burlington railroad, about 25 miles south of Galesburg.

Springfield—About 7350 men are idle in Sangamon County and 36 mines shut down during the suspension. Four thousand residents of Springfield alone are temporarily out of employment.

Chicago—Within a month or six weeks, the Chicago & North Western R.R. will begin the construction of its projected line from Peoria, Ill., to a connection with the Macoupin County Ry., a proprietary company, near Girard, in the south central portion of the state. The new line will give the North Western direct access to its extensive coal fields in southern Illinois. At present, this territory is reached over the Chicago & Alton.

Harrisburg—The last semi-monthly pay day for a number of mines in this vicinity was without doubt one of the largest in the history of the field. The O'Gara Coal Co. disbursed about $130,000, while the Saline County Coal Co. and the Wasson Coal Co. paid out practically $50,000 more.

Kewanee—The Kewanee Coal Co., which has been prospecting for some time on its property two miles east of here, recently encountered a 32-in. seam of coal, at a depth of 275 ft. This is known as the No. 3 or Spring Valley seam. Further drilling will be carried on in order to determine whether or not mining operations are likely to prove practicable.

Indiana

Indianapolis—Except for pumpers and other men employed to keep the properties in shape, the bituminous coal mines of Indiana are deserted and will remain idle until the 20,000 miners receive notice that the wage contract, agreed to in Cleveland, has been ratified by a referendum vote.

Brazil—The block coal and clay mines operated in connection with clay factories in Indiana will continue to work pending a settlement of the wage controversy by referendum vote of the miners, according to action taken by the official board of the Indiana Mine Workers. Some of the factories have their own mines for the production of coal. Their output is not sold elsewhere, and the miners' officials decided to allow these mines to continue in operation during the suspension. The factory owners have agreed to pay the mine employees according to the proposed scale. The most radical change in the local block-coal agreement will be the weekly pay to succeed the semi-monthly pay, a change which will be welcomed by miners and merchants.

Evansville—Following an agreement between Indiana miners and operators, two Evansville railroad mines are continuing to work during the general suspension with the understanding that in the meantime the miners will receive the new scale, or in event of failure to settle on a scale, will receive the rates that their officials have demanded.

Kentucky

Louisville—The operators and miners of western Kentucky were in conference here for five days before the miners drew up a proposition that the operators indicated a willingness to accept. The principal departure made by the miners from the Cleveland agreement concerns the percentage of lump coal in the run-of-mine product. This has heretofore been estimated at 62 per cent., but the miners now demand that in paying the men on a "run-of-mine" basis, allowance be made for the presence of 74.25 per cent. of lump coal. Inasmuch as the Cleveland agreement provides for an increase of 5c. per ton for lump coal (pick mined) and 3c. per ton for "run-of-mine," it can be seen that if the pay of the men were based on an estimate of 74.25 per cent. of lump coal, instead of 62 per cent., the effect would be a further increase over the Cleveland scale. The demands of the men, if granted, will establish a scale in the western Kentucky district of 92½c. per ton for lump coal and 67½c. per ton for "run-of-mine coal. The scale demanded for workmen paid by the day is as follows:

Tracklayers, $2.46; trappers, 75c.; bottom cagers, $2.23; drivers gathering with one mule, $2.46; drivers gathering with two mules or more, $2.67; riders, $2.23; water haulers, $2.23; timbermen, $2.46; pipemen, $2.36; all other inside day laborers, $2.23. For outside work the minimum is fixed at $2 a day. For blacksmiths a minimum of 33c. an hour is asked; for engineers, 35c.; for firemen, 32c.; for night watchmen, $2.23.

The demand that the percentage of lump be raised from 62 per cent. to 74.25 per cent. was qualified by an alternative proposition from the operators that if it be refused an actual test be made to determine the exact percentage.

Montana

Butte—The Trail Creek coal mines, which were closed down Apr. 1, throwing 300 men out of work, will be opened again immediately, as arrangements have been made with the Northern Pacific to operate the branch railway from the mines to the main line of the railroad.

Orders have been received from B. B. Thayer to close down the coal mines of the Anaconda Copper Co. These mines have been in operation 17 years and employ 216 men.

Bozeman—There is a persistent rumor current in this city to the effect that the Chestnut mines, near here, will be shut down indefinitely. The mines have been running on short schedule for several years. The property is owned and operated by the Northwestern Improvement Co.

Missouri

Kansas City—Coal operators of Kansas Missouri, Oklahoma and Arkansas met here, Apr. 5, to outline a proposition to be submitted to the United Mine workers of America, at a joint conference, to be held Apr. 8, when an effort will be made to renew the two-year contract that expired Apr. 1. The mines in the Southwest will remain in operation pending negotiations.

Ohio

Columbus—Operators in Ohio expect little difficulty in the adjustment of a mining scale. Some believe that a fortnight's suspension is all that will be necessary, while others think that it may require 30 days to work out the difficulties. Secretary and Treasurer G. W. Savage, of the Ohio division of the United Mine Workers is confident that the referendum vote will be favorable to the ratification of the wage scale. He believes the result in Ohio should be known by Apr. 15. Ballots for the referendum vote have already been sent out. One of the effects of closing down the Ohio mines will be the release of a large number of cars to the West Virginia fields. Operators in West Virginia have been running with a short-order supply for a good many weeks. As soon as the Ohio operators are able to resume work, a large tonnage will be rushed to Lake points and loaded to wait the opening of navigation. It is believed that, owing to the severe winter, navigation cannot be opened until about the middle of May.

St. Clairsville—The transfer of the property of the Rail & River Coal Co., of Pittsburg, to the Grand Trunk R.R., was made here, Mar. 30. The property lies in the southeastern part of Belmont County, and includes three producing mines in the Pittsburg No. 8 seam of coal, mining equipment and 30,000 acres of coal lands. The Rail & River Coal Co. is capitalized at $250,000.

New Philadelphia—Jeremiah E. Reeves has sued the James Mullins Coal Co., one of the largest coal operators in Tuscarawas County, for $38,000 damages, alleged to have been done to Reeves' coal land in the three years' time that the Mullins company leased it. More than 30 charges of carelessness by the defendants are made in the petition.

The property of the Dennison Mining Co., including 550 acres of coal land in Tuscarawas County, will be sold at public auction, Apr. 29, to satisfy the claims of the Union Trust Co., of Pittsburg, Penn.

Oklahoma

McAlester—It was announced here, Apr. 1, that the miners of the southwestern district would remain at work during the adjustment of a new wage scale. About 1500 miners in this locality are affected.

Pennsylvania

Bituminous

Pittsburg—Coal miners throughout western Pennsylvania will remain idle until Monday, Apr. 22, rounding out a three weeks' suspension in accordance with the decision reached Apr. 3, at the convention of district No. 5, United Mine Workers. The delegates decided to await the result of the international referendum vote to be tabulated Apr. 20. The Mercer-Butler-Armstrong field will be excepted, the men continuing at work with the companies paying the increased wages. There was a general agreement that the Cleveland wage-scale compromise would be approved.

Greensburg—Following the announcement of a wage increase at the various workings of the H. C. Frick Coke Co., other leading coal companies in Westmoreland, Fayette, Washington, Somerset, Cambria, Green and Clearfield counties, have taken similar action. The majority of the employees of these concerns are not affiliated with the miners' organization. Among the companies who have agreed to pay their employees an increase in wages averaging 7½ per cent. are the Jamison Coal & Coke Co., the Keystone Coal & Coke Co., Berwind-White Coal Co., United States Coal Co., Penn Gas Coal Co., Westmoreland Coal Co., Consolidation Coal Co., Quemahoning Coal Co., Somerset Coal Co., Pennsylvania Coal Co., Clearfield Coal Co., Rembrandt Peale Corporation, Peerless Coal & Coke Co., Somerset Coal Co. and over a hundred minor coal companies in the southwestern section of the state.

Uniontown—The W. J. Rainey Coke Co., one of the largest independent producers of the region, recently announced that it would install bath tubs, shower baths and other modern conveniences in all its houses occupied by employees. This is an innovation in the coke region. The company also is making about $100,000 worth of improvements to its plants.

Dubois—By a vote of 91 to 69 the delegates representing 40,000 miners of district No. 2, United Mine Workers, decided, Apr. 3, to accept the recommendation of District President Gilday, and continue working until Apr. 15. If a scale agreeable to the miners is framed in the meantime, work will continue without interruption.

Butler—The coroner's jury which investigated the boiler explosion at the mine of the Turner Coal Co. at Evans City on Mar. 23, when five men were seriously burned, one fatally, found the company guilty of negligence. Charged with neglect of duty, L. B. Gaiser, superintendent of the mine, waived a hearing and was bound over to court in $500 bail, furnished by the company.

Anthracite

Scranton—The suspension of operations in this region and around Carbondale is practically complete. Several washeries belonging to the D. L. & W. and D. & H. companies have been kept running to supply boiler fuel, although the mine workers declare their intention of calling out the men and making an effort to close down all washeries. The Oxford mine of the Peoples Coal Co. recently suspended operations to install a gasoline motor haulage system but is expected to keep going during the suspension just as it did in 1902. A number of small independent mine owners are trying to make arrangements to keep operating in order to supply the local trade. Miners employed at the Jermyn colliery at Old Forge are staying away from work, notwithstanding the fact that they have been offered a 10 per cent. increase in wages and any other concessions the operators in general may ultimately grant. No violence has been reported in this region and the guards formerly hired for times like this are not in evidence.

Wilkes-Barre—Recognition of the miners' union is being brought more and more prominently forward as an issue in the present controversy, independent of an increase in wages. At a recent meeting of a thousand miners at Nanticoke, it was strongly declared that they would not accept an increase in pay unless accompanied by recognition of the union.

The West End Coal Co. at Mocanaqua and the W. T. Payne Co. at Luzerne are keeping their washeries running and are shipping coal. The only steps taken to oppose this activity consisted in calling out the union men employed at the plants.

Hazleton—While peace has prevailed generally throughout the coal fields, there was recently an instance of violence at McAdoo, near here. A fireboss, employed in one of the collieries, was probably fatally injured in a fight, the direct outcome of the suspension.

Pottsville—None of the collieries in the Schuylkill region are working. The plants of the Philadelphia & Reading company had steam up, ready for work, Apr. 2, but no men reported. It is not expected that an effort will be made by any of the collieries to work until after the Philadelphia conference, on Apr. 10, although several individual operators claim that they can get enough men to work their plants whenever they make the attempt.

Shamokin—An attempt of the operators to open the Kathryn colliery, Apr. 3, failed, because members of the union personally persuaded all the men who reported for work to go back home. The company officials say they will try again. That the Reading company expects the trouble to be drawn out was indicated recently, when it ordered all of the mules hoisted from the Henry Clay shaft. The district is absolutely quiet.

West Virginia

Charleston—The 30,000 miners of the Kanawha district received notice from their officials, Apr. 1, that they might resume work pending settlement of the final details of the Cleveland scale, because their markets were threatened by the nonunion districts of the state. The policy committee of the United Mine Workers, at its Cleveland meeting, gave this privilege.

The Charleston-Kanawha Coal Co., incorporated recently and backed by Pittsburg capital, has taken over the coal underlying about 60,000 acres in the Kanawha field, immediately in the neighborhood of Charleston. Development will begin shortly and the operations are expected to become among the largest in the state.

Pocahontas—The Pocahontas Consolidated Collieries Co. has recently purchased the lease and properties of the Cirrhus Coal & Coke Co., for about $107,000. This property is at Big Four, W. Va. Both the No. 3 and No. 4 Pocahontas beds are being mined.

Heavy rains in the Pocahontas field recently, have caused much damage and delay of operations. Two mines were completely flooded, and there were 20 landslides along the Norfolk & Western Ry., between Vivian and Williamson.

Elkins—The mines of the Davis Colliery Co., at Junior, have resumed operations after a shutdown of 13 months.

Welch—At the request of the relief committee of the Red Cross Society, Governor Glasscock, on Apr. 3, issued an appeal for aid for the sufferers from the recent mine disaster at Jed.

England

London—The miners' federation, following a long session, Apr. 6, officially declared off the great coal strike, and ordered the men to return to work immediately. If the surface men's grievances can be settled, there seems to be nothing to prevent a resumption of work throughout the coal fields. The protests of the Yorkshire and Fifeshire miners against the decision of the Miners' Federation are not likely to be followed by action. The miners' associations of these counties have already recommended the men to return to work. General activity prevails in all the coal-mining districts.

Personals

Edward H. Coxe, of Birmingham, Ala., has resigned his position as general superintendent of the coal mines and coke ovens of the Tennessee Coal, Iron & R.R. Co., effective June 1, 1912.

C. C. Anderson, general superintendent of the Northwestern Improvement Co., and E. M. Cortright, engineer of the Montana Coal & Iron Co., have recently been elected members of the Montana Society of Engineers.

Howard Elliott, president of the Northern Pacific R.R., in company with a number of the railroad's officials, recently inspected the coal properties of the Northwestern Improvement Co. in the vicinity of Red Lodge, Montana.

John L. Collin has obtained passports to France and Italy. As a representative of the Pittsburg-Buffalo Co., of Pittsburg, he will sail at once for France to negotiate the sale of a large quantity of coal to the French government.

William H. Grady has resigned his position as chief engineer of the coal mines of the Tennessee Coal, Iron & R.R. Co., effective Apr. 1. C. G. Owen, principal assistant engineer, has been appointed acting chief engineer with offices at Birmingham, Ala.

J. M. Page, division engineer, has been promoted to the position of assistant superintendent of the Pratt No. 1 division of the Tennessee Coal, Iron & R.R. Co.'s coal mines, to succeed William L. Martin, resigned. Mr. Page will be located as heretofore, at Pratt City, Ala.

John S. Critchlow, manager of the Western Fuel Co., of Salt Lake City, has been placed in charge of the Western Pacific Fuel Co., of San Francisco, and will take up his new duties shortly after Apr. 1. The Western Pacific Fuel Co. was recently purchased by the Castle Valley Coal Co., of Salt Lake.

F. D. Underwood, president of the Erie railroad, accompanied by Vice-President Stuart and a party of railroad officials, recently made an extended trip through the coal regions in the vicinity of Scranton, Penn., with the idea of obtaining first-hand information in regard to conditions which at present prevail in this section.

Milnor Roberts, dean of the College of Mines, University of Washington, and Prof. Joseph Daniels, recently accompanied a party of 20 senior and junior students on a trip of mine inspection to Texada Island, B. C. The objects of the trip were to study the deposits of iron, copper, gold and limestone, and to inspect the lime kilns, oil-burning smelters and general mining equipment of the region. Headquarters were established at Van Anda, near the north end of the island.

Chronology of Coal Mining for March

Mar. 7—An explosion of gas in the mine of the Diamond Vale Collieries Co., at Merritt, B. C., killed 7 men and injured two.

Mar. 13—Anthracite operators formally rejected the mine workers' demands.

Mar. 15—Officials of the United Mine Workers refused counter proposition of the anthracite operators.

Mar. 16—An explosion in the Italianka coal mine, Uzovka, Russia, killed 45 men.

Mar. 19—The Interstate Commerce Commission ordered a 10c. reduction in the Pittsburg-Lake freight rate.—Strike in German coal fields ended after conference of miners' leaders.

Mar. 20—Explosion in the Chant No. 2 mine of Sans Bois Coal Co., McCurtain, Okla., killed 74 men.—Conference of bituminous operators and miners opened in Cleveland, Ohio.

Mar. 26—Explosion in the mine of the Jed Coal & Coke Co., Jed, W. Va., killed 81 men.

Mar. 29—Compromise agreement effected between bituminous operators and miners in conference at Cleveland.—Suspension of work in anthracite mines of Pennsylvania was ordered by officials of United Mine Workers.—Bill providing minimum wage for miners became a law in Great Britain.

Construction News

Harlan, Ky.—The Wisconsin Steel Co. will erect another battery of byproduct coke ovens at their local plant during the coming summer.

Ashland, Ky.—William G. Eaton, of Cincinnati, and associates will build 100 byproduct coke ovens, at Ashland. Estimated cost, $1,000,000.

Barbourville, Ky.—The Harlan Coal Co. is installing machinery for manufacturing lumber and will begin work this month on opening its recently acquired coal lands.

Birmingham, Ala.—The Roden Coal Co. will erect 20 miners' dwellings and a new commissary, at the Marvel mine; $20,000 is appropriated for this work. B. F. Roden, Jr., is president.

Uniontown, Penn.—The Superba Coal Co., operating at Evans Station, near here, will make a new opening at its mine and undertake other improvements in order to ship coal on the Pennsylvania R.R. I. W. Buttermore will have charge of the work.

Milwaukee, Wis.—The Pennsylvania Coal & Supply Co. has secured options on 10 acres of land along the water front and will build a coal-storage and transfer dock. The company has recently increased its capitalization from $750,000 to $1,000,000. Jesse B. Whitwall is president.

Birmingham, Ala.—With the completion of the merger of the Woodward Iron Co. and Birmingham Coal & Iron Co. properties, it is expected that the contemplated improvements and developments will go forward. These include the construction of a 400-ton furnace and a battery of byproduct ovens.

Publications Received

REPORT OF INVESTIGATION OF TURTLE MOUNTAIN, FRANK, ALBERTA. By Reginald A. Daly, W. G. Miller and George S. Rice. Memoir No. 27, Canadian Department of Mines. 34 pages. 6¾x10 in., 11 illustrations in text, 19 plates, 2 maps. Government Printing Bureau, Ottawa.

The authors of this report constitute a commission appointed by the Canadian Minister of Mines, to determine whether mining operations in the Turtle Mountain are likely to bring about a landslide, and thus endanger the town of Frank. The commission has also reported on natural conditions likely to produce a slide and has made certain recommendations.

STARTING CURRENTS OF TRANSFORMERS. By Trygve D. Yensen. Bulletin No. 55, Engineering Experiment Station, University of Illinois. 45 pages, 6x9 in., illustrated.

The transformer has come to be regarded as one of the most reliable and simple pieces of electrical apparatus. As new material, however, is utilized to increase its efficiency, new problems arise. One of these problems is the momentary rush of current that occurs upon closing the primary circuit of a transformer. In this bulletin, it is shown that while this starting current for old-type transformers may rise as high as four times full load current, it may rise to more than seven times full load current for the new type with silicon steel cores. The phenomenon is fully explained and illustrated by means of oscillograms.

Industrial Notes

The William J. Oliver Manufacturing Co., Knoxville, Tenn., has received an order for 450 mining cars to be used by the Tennessee Coal, Iron & R.R. Co., at its Edgewater mines. The estimated cost of the cars is $30,000. This is a rush order. The Oliver company some time ago made a reputation on a rush order of cars for the Panama Canal.

The Rock Island Coal Mining Co., of Hartshorne, Okla., announces that having sold the output of its Hartshorne group of mines to the Chicago, Rock Island & Pacific Ry. Co., effective Apr. 1, it feels that the territory served with its Alderson coal will not justify the maintenance of sales forces at Oklahoma City, and Fort Worth, and its sales offices at those points will, therefore, be abandoned on that date. Its Alderson coal will be sold to the McAlester Fuel Co., who will distribute it to the trade.

William L. Rickard and Clifford A. Sloan announce the organization of an advertising company, which will conduct its business under the corporate name of Rickard & Sloan. The offices of the company are located in the Evening Post Building, 20 Vesey St., New York. Particular attention will be given to the planning and management of advertising campaigns for concerns engaged in the manufacture of mechanical and electrical apparatus and accessories. The service of the company will include the writing and placing of advertising in trade and other periodicals, and the production and distribution of bulletins, catalogs and circulars.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The panic prices of last month have been liberally discounted during the week, and the market generally has experienced a sharp recession. The movement is confined almost entirely to contracts, there being little or no demand for coal in the open market. Consumers express entire confidence in the belief that the referendum vote of the miners, upon which the bituminous situation now hinges, will be favorable, and that a general resumption in the soft-coal fields will become effective Monday, Apr. 22. The trade has been further depressed by a heavy selling movement on the part of a large number of dealers, who acquired surplus stocks on speculation, for which they are now seeking purchasers.

In the Eastern markets the trade is practically at a standstill, insofar as new business goes. The milder weather, together with the curtailed production at the mines, has removed the last evidence of the railroad congestion, and good tonnages continue to arrive from districts unaffected by the suspension. Prices on bituminous have slumped freely at all points, but are by no means back to the low level prevailing through the early part of the winter. In anthracite it is believed no great inconvenience will be experienced by the consumers before May 1. There are no supplies in the hands of the wholesale dealers and nothing moving in, while requests for prices are met with the reply that there are no quotations, but the consumers generally are well stocked; shipments so far, this month, have been about equal to one day's run under normal conditions.

The trade in Ohio is busy readjusting itself and making preparations for only a short suspension. Prices have softened considerably, due partially to the feeling that there was plenty of the West Virginia and Kentucky product available. It is thought the suspension will be of sufficient duration to work off the surpluses accumulated in anticipation of the shutdown, and this, together with the shortage in the Northwest, has caused a strong optimistic feeling over the outlook in Ohio. The railroad movement here and in West Virginia is about normal.

Heavy tonnages of Eastern coals were sent into the middle West on speculation, which resulted in the market being overshipped, and the trade is now dull and heavy. No shortage will develop here unless the mines are idle for a month or more.

Boston, Mass.

Bituminous has been generally unsettled since the news of the prospective adjustment of the labor troubles, and a decided reaction has set in against the high prices of the last of March. While it is realized that the output is light for the present, anything like panic prices are liberally discounted, and buyers are simply waiting developments. Many bought from two to three months' supply in anticipation of trouble and they are not interested now except at nearly normal prices. The British situation, too, has so far improved that prices at Baltimore and Hampton Roads have receded considerably, and when the tonnage now engaged is cleared we are likely to see signs of contracting for the usual coastwise market. Something in that line has already been done and there will soon remain only the issue of anthracite to interfere with the orderly course of trade. That we are to have a reasonably active market is almost certain.

All-rail, the stop in mining has enabled the roads to work out of the congestion, and the movement is much improved. A large amount of speculative coal is gradually being absorbed at a rather uneven line of prices, but there are still buyers enough, in urgent need, to furnish a market.

The Southern agencies are out looking to place May coal but there will probably be but small tonnages sold until something like a working basis is reached. It remains to see what will be the base price f.o.b. Hampton Roads and Baltimore, for season shipment. Many of the larger buyers will wait until the market settles down.

With warm weather the public seems to have lost interest in anthracite. The dealers, however, are all short of stocks and are easing the trade as best they can. The recent advances at retail have served their purposes in stopping consumers from putting in next season's supply, and if the suspension is limited to 30 days, the dealers will not be put to such great inconvenience. There is fear that shipments will be very slow when mining is resumed, and that there will be more or less anxiety during the entire summer.

Water freights have further eased off with the chance of anthracite transportation being diverted to soft coal, and the recent slow loading at the Virginia terminals. The old contract year has expired and few charters have been made coastwise on April coal. Large tonnages from Hampton Roads to Boston would not command more than $1.30@1.35, as against $1.50 ten days or so ago. The Reading barge rate on cargoes all bituminous are announced to be $1.20, Philadelphia to Boston.

Coal quotations range about as follows:

Clearfield, f.o.b. Philadelphia.....	$2.75@3.50
Clearfield, f.o.b. New York.......	2.85@3.80
Clearfield, *en route*, f.o.b. mine basis	1.25@2.25
Georges Creek, (April shipment) f.o.b. Baltimore..............	2.70@2.85
Pocahontas, New River, Providence, on cars..............	5.25@5.75

New York

Trade conditions at this point are unusually dull and quiet, considering the labor troubles in effect at the mines. The market experienced a renewed activity during the latter part of last week, but this was only of short duration, and prices now are at the lowest point they have reached since the panicky conditions in effect just previous to the suspension. Some of the large companies continue to take an optimistic view of the situation, and state that they are well satisfied with the outlook, but if prices are any criterion the prospects for an active trade are anything but encouraging.

The curtailment in production at the mines, together with the milder weather, has definitely relieved the railroad congestion, and the movement of bituminous into New York has been good. Water freights are also easier, due to the release of a large number of transports engaged in the anthracite business. Bituminous prices are hardly quotable as few transactions are being made, but are nominally about $2.90@3.25 f.o.b.

The situation in anthracite is somewhat harder as all arrivals have now ceased and everyone is anxiously awaiting the results of the conference at Philadelphia. The anthracite companies have cleaned up their supplies of egg, nut and steam at circular prices, and there is a particular shortage in the steam grades at the present time. It is believed, however, that there is a great deal of anthracite held on speculation. Should the miners and operators reach an agreement, it is probable that such heavy tonnages will be thrown on the open market that prices will decline sharply. On the other hand, should an agreement not be reached, the speculators will no doubt realize handsome

profits. Current anthracite quotations here, are about as follows:

Broken	$5.25
Egg	5.50
Nut	5.20@5.50
Pea	4.50
Buckwheat	4.00
Rice	3.10@3.50
Barley	2.25@2.50

Philadelphia, Penn.

A little touch of winter early in the week had the effect of spurring retail trade somewhat in this vicinity, but it soon fell off again. One- and two-ton lots are about the way orders are coming in, and the dealers are commencing to get a little anxious about the stocks of coal they have on hand, fearing that matters will be adjusted between the miners and operators, before they are able to work off the stocks they were obliged to pay high prices for. It is not thought, however, that there is likely to be a very prompt settlement of the strike issue, as both sides seem to be determined as to what they desire and are willing to give. Some of the large wholesale operators seem to think that the situation is rather critical. Manufacturing establishments in and around the city are conserving their supplies, and making them go as far as possible.

Of course, as far as the wholesale market is concerned, there is practically nothing moving. The receipts so far this month are about what would be produced in one day of normal mining, and this is mostly coal that has already been mined, but just now coming in. Little or no coal is in stock, and requests for prices are met with the invariable response that no quotations or promises of shipments can be made until mining operations are resumed.

Pittsburg

There is no coal market quotable this week, and the mines are idle pending the result of the referendum vote. Operators expect the agreements to be settled in time to open the mines Monday, Apr. 22. As the operators have no coal to ship, the market would be made by such odd lots as speculators could sell and there does not seem to be enough of this to establish any definite figures, though there is a little slack being sold now and then. As to contracts, operators have not quoted prices yet, since the wage matter is not really settled. The basis will presumably be last season's price of $1.15 for mine-run, plus the advance in the mining rate, but subject to such concessions as may possibly develop. No prices have been named yet on lake coal, but the market will probably open up within a fortnight. The ice has been particularly thick, and no boats are expected to get into Lake Erie ports for loading until about May 5.

Connellsville Coke—The coke market has remained stiff, despite the fact that the wage settlement in the union bituminous districts removes the prospect of there being any demand for raw Connellsville coal; it is a question of supply and demand of coke alone. The furnaces do not seem to have called for suspension of shipments to any extent to use up the stocks accumulated in February and March, and coke is still scarce. The market for spot furnace coke is only a shade easier, at $2.30 to $2.40, and the same is true of spot foundry coke, which runs at $2.75 to $3 according to grade. There has been little contracting done, though one or two second-quarter contracts have been put through at about $2. A number of foundry-coke contracts have been made, at prices running from $2.40 up to $2.65.

The New York State Steel Co. has closed contracts for two lots of furnace coke aggregating 12,000 tons monthly for April, May and June, paying a trifle under $2 for one lot and about $2.10 for the other lot, there being a difference in the quality of the two grades. Based on this fact the absurd report has been in circulation that a sale had been made of 12,000 tons a month for the balance of the year at $2.10, which would be an unreasonable figure. Foundry coke has been in light demand and is a trifle easier. We quote: Prompt furnace, $2.40; prompt foundry, $2.75@3, per ton at ovens.

The *Courier* reports production in the Connellsville and lower Conellsville in the week ending Mar. 30 at 413,141 tons, an increase of 15,000 tons, and shipments at 4678 cars to Pittsburg, 6702 cars to points West and 1070 cars to points East, a total of 12,450 cars, or an increase of 800.

Baltimore, Md.

While prices have by no means dropped to the low level prevailing before the recent activity set in, the figures quoted in the Baltimore market during the past week were considerably below those asked two weeks or even one week ago. In numerous instances the best grades have sold at $2.75 per ton, whereas three or four weeks ago, they brought $3.25@3.35, while the lowest grades are selling at $2 or less. This latter grade, when the demand was at its height in March, brought $2.50@2.75 per ton, and consumers purchased it willingly.

Notwithstanding the settlement of the English strike, there were large shipments of coal made from this port during the week to countries which had been depending on the English mines for their supply. Among these were 5000 tons for South America, shipped by the Hutchinson Coal Co., of Philadelphia, and 5000 tons by the Consolidation Coal Co. destined for Egypt.

Many of the Baltimore companies have renewed contracts for the ensuing year, while others have not yet closed with some of their largest customers. One operator stated that not a few consumers were holding off, believing that contracts could be renewed at lower prices than now prevail. The opinion among operators here is that there will be no strike in the bituminous regions. They feel quite sure that concessions will be made on both sides and that the miners will continue at work.

Buffalo, N. Y.

The coal trade is very dull, with next to no anthracite moving and just enough bituminous to keep the jobber anxious. He has done well as a rule during the late stocking-up season, but now finds that there are miners enough at work to furnish all the coal that is wanted, so the prices are very slack. Some members of the bituminous trade are confident that prices will not drop back to the low level of last season, but others find that they have pretty nearly done so already, certain of the cheaper coals being offered last week as low as 95c. at the mines for mine-run.

As a rule the consumers at points easily reached are well supplied and will not buy at any price, but there are other points that are short, mainly on account of the failure of the railroads to deliver the coal. This is quite often the case at small Canadian towns that are dependent on Buffalo as a supply center. The jobber ought to be in a position to take advantage of such conditions, but the roads are as ready to deliver low-priced coal as any, so that the control of the market is very hard to maintain.

While some bituminous coal is selling at prices all the way up to 50c. over old quotations, there is also some moving at about the former figures, $2.60 for Pittsburg three-quarter, $2.50 for mine-run and $2.25 for slack, with coke also not so strong, but usually commanding a little more than the former $4.50 for best Connellsville foundry.

There is now little uneasiness over the mining situation. No prolonged strike is looked for by anyone, though it is believed that the operators everywhere will resist the chief demand of the miners for a recognition of the union. Quite a good many jobbers have made good profits in bituminous coal, but as a rule the mine owners had too many contracts to fill to make it easy to take advantage of the situation.

There is not much prospect of a supply of anthracite right away. Neither the shipping agents of the large companies nor the sellers of independent anthracite have a supply and nobody is making any effort to fill orders. There is not even any selling on future delivery, so that when the trade is resumed it will be new business.

Columbus, Ohio

Following the announcement that there would not be a suspension of more than 30 days at the most, and probably only three weeks, the coal trade in Ohio has softened considerably from the high quotations paid during the latter part of March. With the settlement of the wage scale and the general good feeling existing between the operators and miners, it is believed that the trade will soon be in a normal condition.

Prices have weakened materially, and they are nearer the figures which prevailed several months before the advance. Another factor which tended to keep down prices recently was the feeling that there was plenty of West Virginia and Kentucky coal on hand. Then, again, most of the steam users succeeded in getting quite a surplus, and there is no one now who would pay very high prices.

Jobbers are playing a waiting game and will be on hand when operations are again resumed. There is practically no demand for the domestic grades, and thus prices are about down to the level which prevailed during the greater part of the winter. The steam grades, of course, are in good demand, but prices are much reduced from the high premiums secured two weeks ago.

Operators are looking forward to a good Lake business, as reports show that little or no coal is being carried over on the docks in the Northwest. With a suspension of several weeks or a month, the surplus on the market will be used up, and this will help to keep quotations up relatively high. There are sufficient stocks in the hands of retailers to fill the small orders which are coming in, and no anxiety is felt on that score. Retailers have a large amount of coal which was held up by the congestion in railroad traffic, and this is now being delivered.

Prices prevailing in Ohio fields are:

Hocking Valley	
Domestic lump	\$1.55
¾-in.	1.45
Mine-run	1.15
Nut	1.15
Nut, pea and slack	1.00
Coarse slack	0.80
Pittsburg No. 8	
¾-in.	\$1.40
Mine-run	1.15
Coarse slack	1.00
Pomeroy Bend	
Domestic lump	\$1.80
¾-in.	1.55
Mine-run	1.25
Nut, pea and slack	1.05
Coarse slack	1.00
Kanawha	
Domestic lump	\$1.50
¾-in.	1.25
Mine-run	1.10
Nut, pea and slack	0.90
Coarse slack	0.80

Cleveland, Ohio

The excitement in the strike situation is over, but now comes the enevitable adjustment. Coal was bought at the eleventh hour and the settlement terminated so suddenly that many parties hastily canceled orders, under various excuses. This has caused friction and bad feeling, and naturally so. The situation at this time is practically at a standstill, owing to everyone stocking up in anticipation of a strike, and a good many are dissatisfied that it failed to materialize. However, the precaution was well advised as it was a guess as to the outcome, and it certainly was not expected that a settlement would be arrived at so abruptly.

Hampton Roads, Va.

There has been a decided drop in coal prices at Hampton Roads during the past few days; last Saturday New River and Pocahontas coals were selling at \$4@4.25 per ton f.o.b. and even at \$4.50, while today the same coals are bringing \$3.50@3.75. High volatile coals, considerable tonnage of which was shipped to tidewater lately over the Chesapeake & Ohio and Norfolk & Western Railways, has dropped to \$2.50@2.75, with a lessened demand.

Several of the large selling agencies are in bad shape for coal to load on ships already here, or chartered, and there is still a heavy demand for the best grades, as the vessel tonnage here is far in excess of the coal on hand at the piers. The car supply at the mines has been slightly better during the past week and a further improvement is looked for, but the Virginian Ry., which was getting better movement on its cars, has again been blocked by an immense slide just west of Roanoke, Va. During the first four days of the month 68,167 tons were loaded for foreign ports at the two Norfolk coal piers.

It is reported that the Panama Canal contract for coal, on which bids were made last month, and rejected by the Commission, has been given to the Pocahontas Fuel Co., covering all requirements from Apr. 1, 1912, to Oct. 1, 1914, at a price of \$2.70 per long ton, f.o.b. Hampton Roads. It is understood that the coal may be shipped from either of the three Hampton Roads piers and that it will be divided up among four or five of the largest shippers at those ports.

Charleston, W. Va.

The transferring of engines and cars from other lines to the West Virginia field, especially along the Chesapeake & Ohio, has assisted greatly in relieving a situation that permitted the mines to operate not over half time. Several thousand cars have been thrown over the C. & O. lines in addition to about a dozen engines.

Not all the mines, however, have profitted by the additional cars. Contrary to expectations about 2000 miners have steadfastly refused to return to work since the first of the month. Some of the large mines along the north side of the Kanawha River have not shipped a ton of coal this month. These are mines at which union men are employed and where the foreign element predominate. The instructions of the union officials have been respected by the Americans and not by the foreigners. The latter allege that heretofore when they entered into an agreement to remain at work, pending a settlement of a wage scale, they have always gotten the worst of it. In one case, it is pointed out, that the operators refused to pay the increase between the time of the expiration of the old contract and the new one, although such an agreement had been made.

The great demand for coal and the high prices prevailing, is making the present shutdown expensive to the operators, who, as a rule, have not been enjoying good prices during the past year or two. The operations at Boomer, owned by the Hanna interests, and the Sunday Creek mines near Boomer, are the heaviest sufferers by the failure of the foreign union men to continue at work.

The output of coal in the Kanawha and New River districts during the month of March was 54,150 tons greater than in February, yet the mines were operated on an average of only 9.8 days, owing to a shortage of cars. The output of the Kanawha, New River and Kentucky districts along the line of the Chesapeake & Ohio was 1,508,090 tons.

Louisville, Ky.

Coal dealers of Louisville, both wholesale and retail, are experiencing considerable difficulty in meeting demands upon them, due to reported lack of car facilities at the mines. The retail dealers are not having as much trouble as the wholesalers, as the warm weather has materially decreased the scope of their business for the present.

Wholesalers who supply commercial plants, office buildings, etc., are being put to considerable trouble. Mine operators lay the slowness in delivery to their inability to get cars. The high waters at present are also interfering seriously with railroad facilities. Many of the Louisville dealers have taken time by the forelock and are fairly well supplied with coal, so much so that frequent requests from other cities have come to them for aid.

Nashville, Tenn.

Since the strike has been settled there is very little activity in the west Kentucky coal fields. The usual dullness in domestic lines incident to the warm weather, combined with the extra storing done the latter part of March, means that few of the operating companies have any business or will have for some time.

Screenings are scarce and cannot be had at any price, owing to the inability of mines to move the larger-size coal.

The operators and miners in the union field of west Kentucky are now attempting to settle their differences, the miners contending for the same basis of settlement that was made in Cleveland, which most of the operators are vigorously opposing on account of the competition which they have in this field with the nonunion mines. There seems to be quite a difference of opinion as to whether or not a settlement can be effected in this district, many believing that it cannot, for quite a while at least.

Indianapolis

As a result of the suspension which went into effect Apr. 1, no bituminous coal will be taken from the mines of this state by union miners, except in case of necessity, and then only by permission of the district officials. The suspension differs from a strike, since the miners readily consent to leave pump men and others at work to protect the mines.

The bituminous miners will be out only long enough for the wage agreement to be ratified by a referendum vote. The tickets for this are now being sent out from the miners' headquarters, and it is confidently believed the agreement will be sanctioned by a large majority. It will take at least two weeks to take the vote and will require additional time to canvas the same, so that the bituminous miners are not expecting to resume work much before May 1.

Operators and miners alike are greatly pleased over a settlement having been reached without a long strike. J. C. Kolsem and P. H. Penna, president and secretary of the Indiana Operators' Association, and W. D. Van Horn and Charles Fox, secretary of the Indiana Mine Workers' Association, all express gratification because an industrial conflict was avoided. It is best for the members of the associations and for the industrial world as well, they assert.

Chicago

With the expectation that mines in the Illinois field will resume operations within a month, Chicago coal dealers are now bending their efforts toward readjusting their business to the decidedly lower scale of prices.

There is absolute quiet in the domestic market and steam users are supplied for a month at least. There was a lot of nonunion coal bought on speculation and these buyers lost heavily as a result of the agreement between the operators and miners. Eastern coals were shipped here at a delivered cost of $3 and the same coal afterward sold at $2 a ton, or less.

The screenings situation has occupied a fairly strong position. Screenings of good grade and fair size have brought $2 to $2.25, Chicago. Coke prices are unchanged.

Prevailing prices at Chicago are:

Sullivan County:	
Domestic lump	$2.62@2.87
Egg	2.50@2.75
Steam lump	2.17
Screenings	1.67@1.82
Springfield:	
Domestic lump	$2.57@2.82
Steam lump	2.17
Mine-run	1.97@2.07
Screenings	1.67@1.82
Clinton:	
Domestic lump	$2.52@2.77
Steam lump	2.17
Mine-run	1.97@2.07
Screenings	1.67@1.77
Pocahontas and New River:	
Mine-run	$3.15
Lump and egg	4.05

Prices asked for coke are: Connellsville and Wise County, $4.85; byproduct, egg and stove, $4.95; byproduct, nut, $4.75; gas house, $5.

Minneapolis—St. Paul

Coal men in the Twin Cities are doing nothing and the trade is practically at a standstill. Men who have been in the coal business for over 20 years say that never before have they seen the time when business was as quiet as it is at the present time. Generally this period of the year is contracting time, but no one seems to have any prices and, although they have numerous inquiries from parties regarding contracts, they are not at liberty to sign up.

Since the Health Department of Minneapolis, especially the smoke inspector, together with the Civic Commerce Commission, has become quite aggressive in seeking to abate the smoke nuisance, representatives of wholesale companies held a conference with Smoke Inspector Allen to know what his attitude was toward coal other than the so called smokeless coals.

The coal men contend, of course, that the coal from other fields should continue to have a fair show in the steam trade in this city and that from the standpoint of efficiency, Illinois, Indiana, Ohio and Pennsylvania bituminous coals could be shown to have many good points in their favor, and the Health Department should not commend or recommend any one coal for use in plants. Mr. Allen, the city smoke inspector, made it clear that it was not the intention to favor any one coal, but that it was a matter of educating the consumers to the installation of automatic stokers and the correct combustion of fuel, all of which would take time to bring about. He asked for the coöperation of the coal trade in bringing about better conditions in the firing of coal in order to minimize the present nuisance from excessive smoke.

The retail coal business in both cities has been exceptionally dull during the past week as the weather has been very mild.

St. Louis, Mo.

There is very little doing in the St. Louis coal market. As a matter of fact, it is at a standstill, although, on good authority, it is understood there will be no shortage of coal in St. Louis if the mines remain idle for four weeks. There are several hundred cars of coal on track on the east side of the river and at the mines on the railroads owned by coal-producing companies, and there is very little outside coal coming in.

A few cars of smokeless are straggling in, but there is nothing in the way of anthracite, and Kentucky coal is practically a thing of the past, unless something unforeseen comes up. However, there is still a few cars of Kentucky coal coming in on contract, but the bulk of that coming to St. Louis has been disposed of by a Tennessee selling agency in Chicago; this amounted to 10,000 tons.

There is no shortage in this market and probably will not be, as everything indicates that the miners will vote for acceptance of the terms as submitted to them by their representatives and the operators. The mines will probably resume work between Apr. 20 and the first of next month.

A Chicago coal man, with a mine in Franklin County, and a St. Louis office, offered to build a half mile of railroad at East St. Louis, connecting the L. & N. with the I. C., if the railroad would furnish the steel, in order to get the L. & N. to allow their equipment to go to Chicago. The L. & N. turned the proposition down flatly, unless they were guaranteed an empty coal car in return for every load they delivered the I. C., the same to be delivered on the same day. It was impossible to make the guarantee, and consequently the coal was sacrificed on the St. Louis market, and helped further to depress prices.

Portland, Ore.

Coal dealers are not at all optimistic over the outlook here, one of the chief reasons being the extensive introduction of oil. In a great many instances oil is supplanting coal here and throughout the state at steam plants. But with the opening of the Panama Canal, it is expected there will be a good demand for coal, as the great majority of vessels engaged in the coast to coast trade will probably be coal burners. The steamers in the coastwise trade are now burning chiefly oil.

The demand for coal has been very light here this winter, and there is some complaint coming from the old dealers to the effect that much inferior coal has found its way on the market. Storage prices will probably not be made effective for a couple of months yet, although the

weather is already summerlike here. It is expected that the Eastern coal strike may have some effect on the Wyoming coals, and, if this should prove true, local dealers will have an opportunity to gain some of the profit they had in view last winter, which failed to materialize because of the mild weather.

A great deal of interest is taken in the Alaskan coal fields, and if they are thrown open to development and cheaper coal made available, manufacturing will be given a strong impetus. For the present the freight is preventing coal from meeting with the demand here that dealers would like to see.

San Francisco

Imports by sea during the past week comprise 9462 tons of British Columbia, and one cargo, 5160 tons, of Pocahontas, the latter consigned to the United States government for navy uses. Car shipments from the Rocky Mountains were normal; the demand for this coal keeps good, and had it not been for the accumulated stocks in dealers' yards, due to the mild winter, receipts would doubtless have been much heavier.

The Western Fuel Co., a San Francisco corporation, owning large collieries in British Columbia, has been for some time past the dominant factor in this market, so far as British Columbia and Australian coal is concerned. Recently this company absorbed the coal business of a local firm, which was a direct importer and distributor of Australian, and now, as a matter of fact, it has no competitor in either this or the British Columbia product.

While, as previously stated, no accurate data are obtainable as to the quantity of Rocky Mountain coal coming into this state, there can be no question but that it is gaining in favor and securing a strong foothold in the domestic trade; the quality is well liked on account of its cleanliness, and the lower freight rates have enabled the colliery owners to land it here at reasonable prices.

Current prices to dealers are as follows, per ton:

Wellington (British Columbia)	$8.00
Pelau Main (Australian)	8.00
Rocky Mountain	8.50
Cumberland	12.50
Anthracite (Pennsylvania)	15.00

Production and Transportation Statistics

Baltimore Exports

For the period of three months; that is, January, February and March, 149,320 tons of coal were exported from Baltimore to consumers in 11 different countries. February tonnage was heavy, 41,129 tons having been shipped from this port during that month, but the demand was the heaviest during March, when 83,536 tons were loaded here for foreign ports. In January, the tonnage was light, totaling 24,655 tons, as in that month, the strike in England had not yet begun.

Exports

Total exports of anthracite during January, 1912, were 221,854 tons, as compared with 251,737 for the same month last year. Bituminous exports for January, 1912, exclusive of bunker coal, were 667,263 tons, as compared with 740,974 tons for January, 1911. Bunker or fuel coal laden on vessels in the foreign trade amounted to 552,965 tons in January, 1912, as compared with 481,874 tons for same month last year. Exports of coke for January, 1912, were 53,114 tons as compared with 87,578 tons in January, 1911.

Alaska

Shipments of coal to Alaska for January, 1912, were 523 tons as compared with 1107 tons in January, 1911.

Porto Rico

Anthracite shipments to Porto Rico for January, 1911 and 1912, were 1695 and 305 tons respectively. Bituminous shipments for the same months were 8203 and 2233 tons respectively.

Domestic Coastwise Movement

The following is a comparative statement of domestic coal shipments from the five principal Atlantic ports for January, 1911-12, in long tons:

	1911	1912
New York	2,355,276	2,337,474
Philadelphia	555,723	436,361
Baltimore	422,840	265,050
Newport News	244,022	212,194
Norfolk	285,880	389,781
Total	3,863,741	3,640,860

Pennsylvania Railroad

The following is a comparative statement of coal and coke carried on the P. R.R. Co.'s lines east of Pittsburg and Erie for the first two months of 1911-12, in short tons:

	1912	1911
Anthracite	2,147,761	1,938,093
Bituminous	7,668,282	6,594,e38
Coke	1,964,184	1,683,771
Total	11,780,227	10,216,002

Anthracite Shipments

March	1912	1911	Changes
Phila. & Read.	1,472,696	1,057,279	+115,427
Lehigh Valley	1,225,019	1,086,529	+138,490
Cen. R.R. of N. J.	848,110	768,031	+180,079
Del., Lack. & W.	916,824	738,499	+178,325
Del. & Hudson	578,983	698,443	—119,460
Penn. R.R.	537,470	586,016	— 48,546
Erie	761,742	811,357	— 49,615
Ont. & West.	288,843	250,740	— 21,897
Total	6,596,687	5,996,894	+572,793

Production of coal in the first three months of 1912 was 18,209,351 tons, as compared with 16,971,959 tons in 1911, an increase of 1,237,392 tons. These are the heaviest shipments in the quarter of any year.

The Car Situation

The releasing of a number of cars by the more favorable weather resulted in a big increase in the latest idle car statement, for the period ended on Mar. 27. Two weeks earlier the shortages reported in various parts of the country almost resulted in wiping out the net surplus, and the total number of cars reported on that date, which was 3043, was the smallest in years.

The exceptional record which has been made in recent weeks in this line was also explainable in part to the unusual activity of coal shippers who were preparing for the expected strike by getting as much coal on the markets as possible. Two weeks ago there were shortages both in coal and box cars.

There was a total surplus on Mar. 27 of 52,682 cars, shortages in other districts bringing down the net surplus. This indicates the difficulty the companies have experienced in effecting a proper distribution of their free equipment.

Financial Notes

The annual report of the Island Creek Coal Co. for the 1911 calendar year shows net profits of $531,612, equivalent to $2.34 on the 99,568 common shares after payment of preferred dividends.

The annual report of the Delaware & Hudson Co. for the year ended on Dec. 31 shows a surplus of $5,237,000, which is equivalent to 12.32% on the $42,503,000 of stock outstanding. Last year the company earned 12.54%. It is paying annual dividends of 9%.

The listing committee of the New York Curb Market Association has approved the application of the Lehigh Valley Coal Sales Co. to list the outstanding 121,216 shares of the common stock, par value $50 full paid. The total amount authorized is $10,000,000. The Bankers' Trust Co. is registrar for the stock and the transfer agency is located at 90 West Street.

Steel conditions in Canada being largely in sympathy with those in this country, earnings of the Nova Scotia Steel & Coal Co. for the 1911 fiscal term ended Dec. 31, amounting to $1,019,392, exhibited a loss of $121,112 from those of 1910, although they were larger than the figures of 1909. The balance after all charges was $450,342, or $65,853 less than the previous year. while the surplus after preferred dividends of $367,942 was equivalent to 6.13% on the $6,000,000 common stock as against 7.23% in 1910. As 6% was paid on these shares, the net surplus for the year was only $7942, compared with $163,795 the season before.

Another appeal is to be made to the stockholders of the Bon Air Coal & Iron Co. to accept the plan of reorganization suggested last September by the committee composed of Joseph H. Thompson, Maj. E. B. Stahlman and Byrd Douglas. A letter is being sent out by the committee composed of Judge J. M. Dickinson, P. D. Maddin and Edgar Jones, calling attention to the condition of the company. It is stated that for seven months of 1910 the net earnings of the company under operation by the receiver amounted to $62,226, and that for 1911 the net earnings were $47,589, though 1911 was one of the hardest years of history for the iron industry.

HYATT STANDARD BUSHING

INTRODUCTION

FEW recent applications of known mechanical principles make a more general appeal than that of the roller bearing as applied to saving energy. Repeated demonstrations and tests by large industrial companies show that roller bearings save from 10 to 60 per cent of the energy ordinarily required to produce a given result, and it is natural to predict that the time is not far distant when the adoption of roller bearings will become universal.

COAL AGE

Vol. 1 NEW YORK, APRIL 20, 1912 No. 28

COMPETITION on the part of laboring men themselves has ever been the chief force to beat down wages. To overcome this condition has been the first aim of labor unions. The principal argument advanced to justify the organization of workingmen is parallel with the idea that a theatre or other crowded building can be more speedily and safely emptied when accomplished in accord with some systematic plan.

Labor leaders discourage tumultuous action, where each person pursues his own individual interest with ignorance, passion and fear. Also, they have accepted as their own the modern idea that "an increase in wages by raising a man's laboring power may enlarge the product proportionately; that underfeeding, whether of man or animals, is false economy."

The question uppermost in our minds to-day, however, is whether strikes are necessary and advisable measures for the betterment of workingmen's social conditions. One or two generations ago, labor wars in England, although not as frequent, were invariably successful. The men were striving simply for enough to eat. Unfair laws had reduced them below the economic point of subsistence. Wage controversies to-day are not always for such a palpable cause.

As to the success or failure of workmen in their contests with employers, no one should so lack in discernment as to believe that when a strike fails to advance wages, the laborers have lost in their fight. We might as well believe the French Revolution was a failure because the Bourbons were restored to power. The king and princes returned, but to rule a new France. The master may remain master, but the dread of another conflict makes the old regime forever impossible.

There is no constructive or healing virtue in a strike. Insurrections of labor, like uprisings in the political body, are purely destructive agencies. Yet, as a rebellion against corrupt government may destroy political institutions that have outlived their usefulness, so a labor war may break up a crust of custom which has formed over the remuneration of a class of workmen.

However, a strike can only justify itself by its results, and unless it makes way for a better order of things, it is waste of the worst sort. Not only is production curtailed, but bad blood and bad habits result from the enforced idleness. Few of us but abhor strikes, and pray for the advent of a saner method of eliminating poverty and restoring freedom. Still we all have to admit that nothing so quickens the sense of justice and equity as does the consciousness that unfair acts are likely to be promptly and fearlessly resisted.

As to the real cost of a strike, and the actual money losses incurred, the truth is that we generally overestimate the dire results. In an industry like coal mining where the productive capacity is so far above requirements, a cessation of work, if not too prolonged, frequently results in clearing up the market situation, and eventually brings benefit to operator and miner alike. Enforced idleness is always succeeded by increased activity and the loss of time is soon made good.

The danger to business of all kinds today is not so much from spontaneous strikes brought about by inhuman, unjust treatment of workmen by employers, but from shut-downs ordered by trades-unions and founded on exactions that cannot be maintained. It often occurs that a slim minority, who give scant consideration to the equities of distribution, frame demands that are both offensive and impossible, and which owners could not concede, if they would, without checking production and diminishing employment.

There is a singular impotence in conspiracy. This is shown by the fact that the most successful strikes arise from a common sense of injury to an outraged body of workmen. Frequently when plans have been carefully made and the machinery of insurrection extensively employed, the attempt to better wages has ended in ignominious failure. When labor is organized to a point of military discipline and the men are under obligation to obey all decrees, action of doubtful legality or expediency is apt to be prompt and arbitrary. *In our next issue, we will endeavor to show how the unwise and improper exercise of newly acquired power is likely to hinder rather than help the workingman's cause.*

The Dewar, Oklahoma, Coal Field

By John A. Garcia *

The Dewar field is an excellent example, on a small scale, of the benefits derived by consolidating the small individual operators. The "gopher" system of mining has been succeeded by more modern methods and electricity is being successfully applied. A rather surprising and unusual feature, for a coal mine, is the practice of burning natural gas in the boilers.

*Mining engineer, McCormack Building., Chicago, Ill.

The coal-mining town of Dewar, Okla., is located on the edge of what is probably the greatest oil field in the West, in Okmulgee County, on the Coalton branch of the Missouri, Oklahoma & Gulf R.R., and about three miles east of the older and well known town of Henryetta, on the 'Frisco Road. Two years ago Dewar was only a water tank and coaling station for the M. O. & G., and nearby were a few slope mines, operated under lease in a very crude and spasmodic fashion, producing nothing in the summer and about 50 to 130 tons per day in winter.

No incentive or encouragement of any kind was offered for the development of the field, mainly because of the oil and gas produced in the immediate neighborhood. This latter is used as a fuel and illuminant by practically all the railroads, manufacturing plants and for domestic purposes, in fact these pioneer coal operators found it more economical to tap the pipe lines running past the mines and use gas under the boilers and for lighting the few houses in the camp. The famous Kiefer oil field is only 40 miles from Dewar and a capped gas well, said to be the largest in this country, was drilled on the edge of the town and plugged up as there was no market for the product.

Surface Plant at Mine No. 3, Showing Typical Arrangement at a Shaft Mine

Economic Considerations

The promotors of the Oklahoma Coal Co., after carefully considering the question of competition from oil and gas, decided that such competition had a very limited future and that a good coal, well prepared and sold at a reasonable price would find a ready market on the new M. O. & G. R.R., then building down through Oklahoma into Texas.

After thoroughly investigating the operating conditions, and being satisfied that they could be handled and the coal placed on cars at a reasonable figure, the several operations were bought up and some 3000 acres of coal acquired. The Oklahoma Coal Co. was formed, organization perfected, and the work of rehabitulation and reconstruction begun.

Several of the older producing mines with but a short life ahead, were leased to responsible parties on a royalty basis, while the operations having good prospects for a future were surveyed, mapped and projected. The haulageways were then brushed and graded, ventilation established and the mines overhauled generally from top to bottom. Most of the mines had been ventilated by furnaces and, as it was obviously impossible to successfully operate for large tonnages with these, fans were installed at all the mines. These are all of the suction type and the slopes are made the intake.

Methods of Working

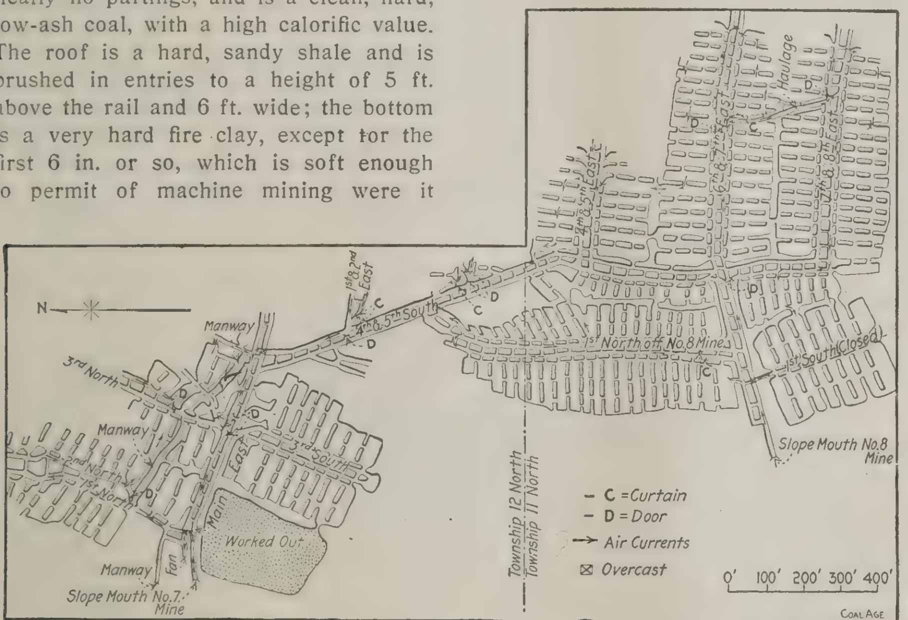
The accompanying halftone shows the No. 3 mine which is a shaft about 50 ft. deep and will be the banner mine of the field. All the coal is caged on one side, and the empty cars run by gravity to run-a-round; the cage room is double tracked and long enough for the storage of 60 cars. Overcasts are used at each pair of cross entries and there are no doors on the main entries. Various other improvements, which are common enough in other states, but considered rather revolutionary at Dewar have been installed.

The railroad follows the outcrop of the coal which can be readily traced along the foot of the hill all the way to Coalton and beyond. The seam measures from 3 ft. to 3 ft., 4 in., has practically no partings, and is a clean, hard, low-ash coal, with a high calorific value. The roof is a hard, sandy shale and is brushed in entries to a height of 5 ft. above the rail and 6 ft. wide; the bottom is a very hard fire clay, except for the first 6 in. or so, which is soft enough to permit of machine mining were it not for occasional boulders and rough places in the floor.

The coal pitches at the outcrop on an angle varying from 5° to 20° for about 100 ft. From that point on there is no regular inclination or pitch, but enough variation in grades to make the systematic projection of workings very difficult and in some instances impossible; especially is this so at the present time when all hauling, except on the main entries at No. 7 mine, is done by mules.

The accompanying map shows the workings of the combined Nos. 7 and 8 mines. The irregular system of working is due to the extreme variation in the pitch of the seam and to the gophering methods commonly used under the old leasing system of Oklahoma where no fixed percentage of extraction was demanded.

An electric hoist is used to pull the trips up the slope at No. 7 mine and partings are now being built inside so that by means of a tail-rope the mule haulage on main roads will be materially reduced.



The Oklahoma Coal Co.'s Mines Nos. 7 and 8, at Dewar, Oklahoma

Shooting from the Solid

Before the advent of the Oklahoma Coal Co. all coal was shot off the solid, except in No. 8 where the clay was mined by hand and an excellent grade of lump coal produced. The great difference in the mining rate, however, (80½c. for solid and $1.05 for pick-mining) and the fact that only the coal with thin cover could be hand mined forced all mines to the solid basis; this has resulted in high percentages of screenings, windy shots and the other innumerable evils which accompany this system. The mines generate no explosive gases and this, together with the fact that the brushing mixes powdered shale with the coal dust, probably accounts for the fact that there has been no explosion or even serious windy shot in the history of these mines.

Chain machines were tried in the No. 6 mine. They were tested in the clay bottom and in the coal and several makes of machines, including both breast- and short-wall, were tried. The tests covered a period of six months and met with uniform and consistent success in each instance, with, however, the customary variation in efficinecies for the different makes of machines due partly to design and partly to the machine men. The machines readily mined the clay but it took so much more power, and was so difficult to keep the nose of the machine in the clay, that it was decided to cut the coal only, though it meant about 14% fine coal to begin with and 5 in. less height, which is an important matter in a 36-in. seam.

The Sullivan short-wall chain machine was finally adopted as a standard, but on the test run with a breast-machine, to determine the proper differential, the miners running the breast-machine were a little to smart for the company men operating the short-wall, and the differential between the two types was established, at only 2½c. per ton, fixing the machine scale at 78 cents.

Power Plant

Electricity for the machines at the various mines is supplied from a central power plant located near No. 5 mine, equipped with a 300-kw., 2200-volt, alternating current, General Electric generator, direct connected to a 21x20-in. Ridgway engine. The power is distributed to the mines over a pole line carrying 3, No. 0 wires, securely fastened to porcelain insulators and made as inaccessible as possible. Motor generator sets are provided at mines Nos. 6, 7 and 8, and there is a transformer at No. 7 for operating the electric hoist. At No. 5 the power is supplied by a 75-kw., direct current, 250-volt, generator which the company had on hand. The boilers are arranged in a battery of 3, and are 18 ft. by 72 in., of 150 hp. each, gas fired and built by the Casey-Hedges Co., Chattanooga, Tenn. Both boiler and engine room are arranged for an additional 300-kw. generator, the necessary boiler power to be installed when development of the mines require it.

Because of the rock top and freedom from water, the mines can be shut down in the summer months and reopened in a few days' time at a nominal expense; on account of the competition of the oil and gas, there is little or no demand for coal through the summer, so that the fact that the mines can stand a long shut down without injury is a very valuable condition, without which it is questionable whether or not they could be profitably operated. The operators on the M. O. & G., however, believe that the six months operating and six months shut down arrangement, will not obtain much longer for the mines on that road, since the product is sent into the large cities in Texas and through a country where the domestic fuel consumption is rapidly increasing.

With anything like fair running time, these mines in the Dewar district will, when fully developed, have a marked influence on the coal business in Oklahoma. They are free from the usual unfavorable conditions such as gas and depth and the heavy pitch so that the production cost will be comparatively low and this fact, together with the good quality of the product and the location on a coal road, make a strong combination in the competitive market.

Water Purification for Collieries

Special Correspondence

Undesirable water may be prepared for use in boilers and for other purposes by the addition of chemical reagents, by preheating, or by a combination of the two methods. Several hot and cold processes are here outlined and the manner of their operation explained. The second of a series of articles on water purification.

In a previous article, it was stated that the subject of water purification for collieries could be dealt with best under the two general heads of hot and cold methods of treatment, and one notable system of water softening by the cold process was described in detail. In some of the types of water-softening apparatus made by Lessen & Hjort, the cold process is used and lime is employed as the reagent.

This form of apparatus will best be understood by reference to Fig. 1. In general it consists of a combination of a measuring and mixing apparatus, settling tanks and a filter, for the purpose of removing the precipitated impurities from the water. The hard water, on entering the softener, passes alternately to each of the two compartments of a tipping device, which oscillates on a horizontal shaft. When either of these compartments is filled with water, the center of gravity is shifted, causing the tipper to over-balance and discharge its contents into an inclosing tank. This brings the other compartment of the tipper under the inlet pipe and it is in turn filled, the center of gravity then being shifted to the opposite side and the tipper caused to overturn in the reverse direction.

Lime Milk Added in Definite Quantities

In this way the oscillation of the tipper is such as to discharge a definite volume of water into the tank at each stroke. Following each discharge, a corresponding amount of water is displaced from the tank and led through a standpipe and chute into the reaction chamber of the softener. At the same moment, the requisite charge of chemical solution is delivered through a valve placed on the bottom of the semicircular chemical container *D*, and operated by the tipper. This valve can be regulated, while working, to discharge the exact quantity of reagent required by the volume of water in the tipper compartment, and in this way the proper amount of reagent, which is calculated to reduce the hardness to a guaranteed figure, is added without altering the solution in the chemical container.

Lime milk, of a 10 per cent. strength, is generally used for the lime reaction, and as this milk has a strength nearly 100 times that of lime water it is possible to employ tanks of a correspondingly smaller size than those required when the latter mixture is used as a reagent. Moreover, since a known quantity of lime can in this case be mixed with a known quantity of water, the strength of the solution obtained is definite. The heavier portion of the precipitate settles on the bottom of the reaction chambers and is discharged from them daily by opening the sludge valves for a few moments. The finer portions of the precipitate are removed by wood-wool filters, packed between rows of wooden bars.

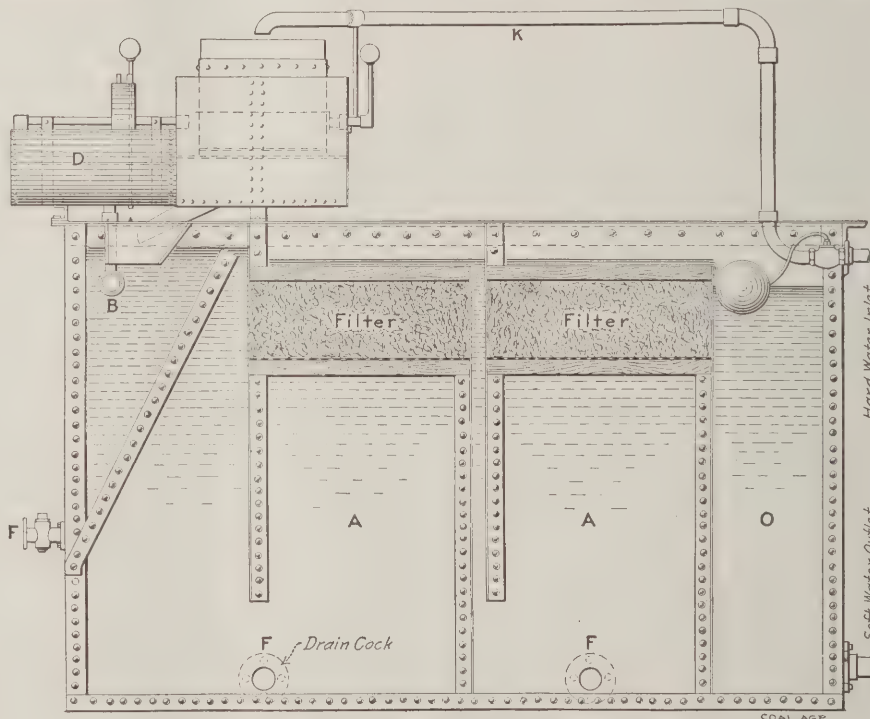


Fig. 1. Lessen & Hjort Cold Process Water Softener

In some cases, Messrs. Lassen & Hjort's softeners are made cylindrical instead of square in form, but this difference is purely mechanical, the method of operation being the same. The cylindrical type, however, allows the discharge to be taken off at a higher level. The chemical container, which is calculated to hold from 10 to 12 hours' supply, is frequently supplemented by a mixing tank, placed on the ground level, with a capacity sufficient to fill the container several times. A pump is employed to supply the solution to the container, and an overflow pipe brings back any excess. Connected with the pump gear, is an agitator which operates inside the tank for the purpose of rendering the mixture homogeneous. In this way a lime milk or sludge of uniform quality is transferred to the container. The pump may be operated either by hand or by power, and in some cases, is driven by a water motor which is connected to the supply of hard water on its way to the softener.

A number of successful installations operating on the Lassen & Hjort principle have been effected at collieries in Great Britain, and other mining installations have been made in places as distant as Mysore, Wallaroo, Huelva, Kobe and Servia. A most interesting plant is one with a capacity of 18,000 gal. per hour, installed at the Askern colliery at Doncaster.

Automatic Measuring of Reagents

A mechanism somewhat similar to the foregoing, is that of the "Eradica" water purifier, manufactured by Messrs. Ashwell & Nesbit, Ltd., of Leicester. The measuring apparatus, in this case also, consists of several oscillating vessels, arranged alongside one another on the same shaft, each auxiliary vessel being connected by an annular passage to the one used for measuring the untreated water. The crude water first flows into the main vessel and is then distributed in definite proportions to the one or more subsidiary compartments. The size of these subsidiary vessels is adjustable and can be arranged to deliver a definite volume of displacing water either to a lime saturator or soda-solution tank.

The arrangement of one form of this measuring apparatus is shown in Fig. 2, in plan and vertical section. It will be noted that a definite volume of water is delivered to each reagent receptacle in proportion to the volume of crude water measured out for purification. Both lime and soda reagents are used in diluted form. Except for charging the lime saturator and soda solutioner and sludging the apparatus, the installation works automatically.

Before passing to the consideration of softeners in which use is made of steam, it will be interesting to refer to the "Reisert" type of purifier which has been supplied to a number of collieries, among which may be mentioned those of R. Evans & Co., of Golborne, near St.

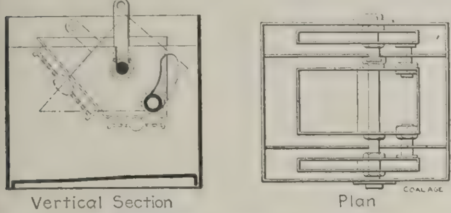

Fig. 2. Measuring Device

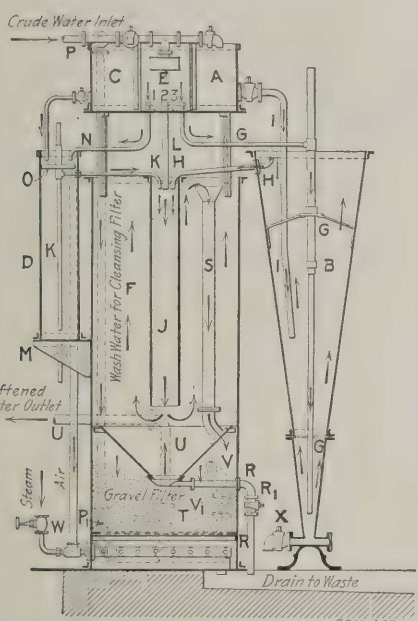

Fig. 3. Reisert Purifier

Helens, where there is a plant dealing with 4400 gal. per hour. The general arrangement of the softener is shown in Fig. 3.

Feeding in the Soda Solution

Lime, slaked in a vessel *A*, is run down a pipe marked *I* into a conical chamber *B*, after the previous spent charge has been run to waste. A regular and known quantity of water passes through the micro-valve marked 3 along a pipe *G* to the bottom of the cone and then upward through the slaked lime, becoming saturated, but not over-saturated, with the lime. As the water proceeds upward its velocity diminishes, owing to the expanding nature of the container and any excess particles of lime settle back until they are dissolved in additions of water. The lime water then passes in a perfectly clear state to the top of the vessel *B*.

A certain quantity of soda is dissolved in the container *C* and runs into the vessel *D*. A regulated quantity of water passes into the top of *D* by way of the micro-valve 1 and the pipe *N*. Since the specific gravity of the soda solution is greater than that of water, it settles to the bottom of the tank, and the incoming crude water is discharged on the float *O* in order to prevent any mixing in the top layers. As the level of the soda solution gradually sinks in the vessel *D*, some little head is required to force it up the pipe *K* as far as the discharge. Consequently the amount of soda solution passing to the mixing pipe *J* is proportional to the amount of water flowing in from the micro-valve 1.

The third quantity of crude water passes directly to the mixing pipe *J* through the micro-valve 2. All these three micro-valves are under the same head so that proportionality is preserved. The mixture of the reagent solutions and the crude water is carried down pipe *J* to the bottom of the reaction chamber. A certain proportion of the precipitated matter is deposited and sludged out by the cock *R* from time to time. The water then overflows from the reaction chamber to the gravel filter *T* where all suspended and floating matter is arrested.

In order to clean the filtering material, a mud outlet valve V_1 is opened,

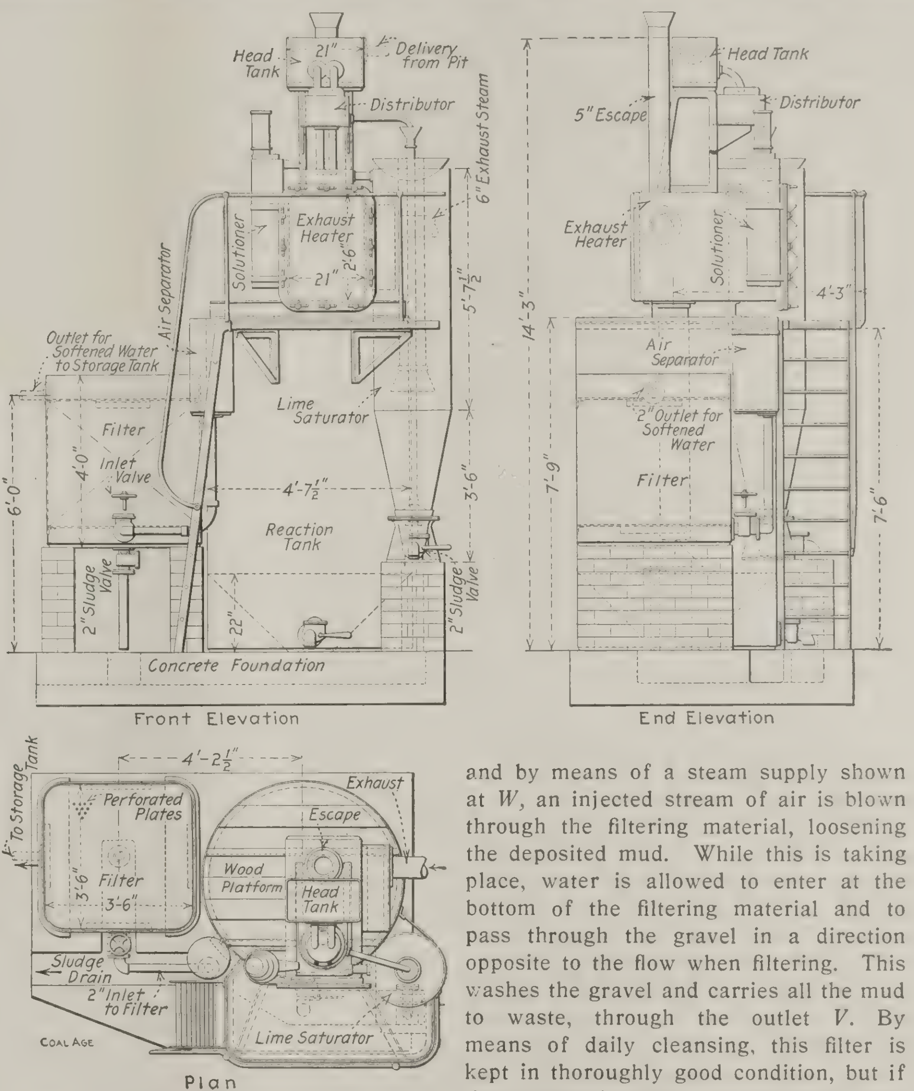

Fig. 4. Heater and Softener

and by means of a steam supply shown at *W*, an injected stream of air is blown through the filtering material, loosening the deposited mud. While this is taking place, water is allowed to enter at the bottom of the filtering material and to pass through the gravel in a direction opposite to the flow when filtering. This washes the gravel and carries all the mud to waste, through the outlet *V*. By means of daily cleansing, this filter is kept in thoroughly good condition, but if the untreated supply is particularly hard and dirty, as is possible in the case of mine water, purified water is used for cleaning the filter.

Preheating with Exhaust Steam

The availability of exhaust steam, from hoisting engines and similar sources at the collieries has made it extremely convenient, in a good many cases, to do without the use of lime for the removal of temporary hardness, and to employ steam to boil the water before entering the boiler, thus removing its calcium and magnesium carbonates. However, where there is also permanent hardness in the water, a combined heater-softener is employed. In this, the action of steam is combined with the injection into the water of a softening solution, usually of soda ash.

The various manufacturers of water-softening apparatus install hot processes, where required, instead of the cold processes already mentioned and but little alteration in the details of design is necessary in order to adapt the plants above described to the functions of the hot process. It will, therefore, not be necessary to recapitulate these designs in detail. In the Lassen & Hjort combined water heater and softener, for example, the water measured and mixed with chemicals, as described above, is heated to the boiling point by means of exhaust steam led into the precipitating chamber. This chamber is provided with a guide plate and sludge cock to facilitate the removal of the large quantities of precipitate which are deposited here. The further deposition of the heavier precipitate takes place in a settling chamber. The water is then filtered, settled and again filtered before passing to the storage tank.

In this type of softener the use of lime is not dispensed with. The makers point to the fact that exhaust steam usually contains a considerable amount of oil, and unless this is coagulated by the action of the lime, it is apt to be carried over into the boilers. This system, it is claimed, effects softening independently of the use of heat.

Combined Heater and Softener

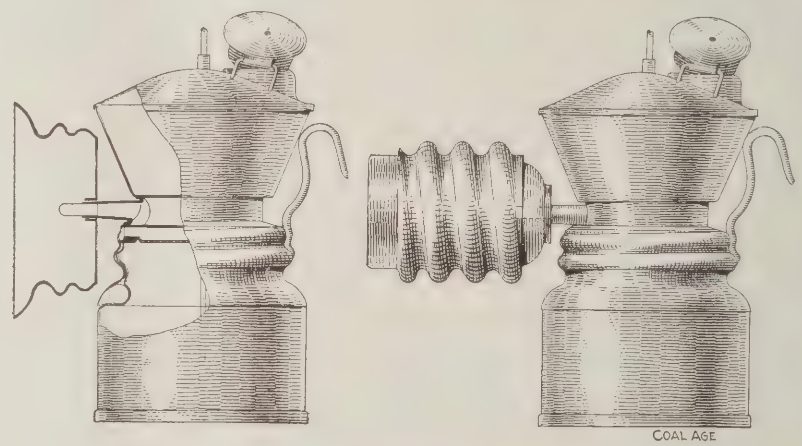
One of the Harris-Anderson water softeners, installed at a colliery in Cumberland, where the water is pumped from the mine and heated by exhaust steam in its passage from the plant, is shown in Fig. 4. In some types of the Harris-Anderson apparatus, where the chief function required is the elimination of oil from the water before it passes to the boiler, the lime saturator is done away with and two solutioners are affixed, one for soda and the other for alum. The bulk of the water passes directly to the treatment tank, while fractional portions are carried by the distributor to solutioners in which the cages are filled respectively with the two reagents. The action of the alum solution is to coagulate the oil. All the water passes to a filter of the usual type which is frequently divided into two independent sections so that one can be cleaned while the other remains in action.

Experiments made in England with calcium chloride as an agent for laying dust in coal mines have shown that a 40- to 50-deg. solution used at the rate of 8 gal. for every 30 ft. will lay dust 3 in. thick and the zone so treated will be safe for a period of 3 months. A roadway cleared of dust for 225 ft. and then treated with 90 gal. of calcium chloride solution was found to remain moist 4 months; 330 lb. of finely ground solid calcium chloride on 250 ft. of roadway was effective for 6 to 8 weeks.

Shields for Acetylene Lamps

By Joseph Daniels*

During a recent trip through the mines of the Roslyn district in Washington, I noticed a device which some of the men had adopted to protect the flames of their acetylene lamps. In exceptionally windy or blowy places, the reflectors ordinarily furnished with the lamps did not afford sufficient protection for the flame, particularly in the cases of trip riders and locomotive men. The scheme which they had adopted here consisted in removing the usual reflector from the lamp and substituting for it the screw top of the extra bottom which is furnished with the Baldwin lamps. By simply perforating this top at the center it was found possible to slip it over the lamp tip and secure it as indicated in the illustration.



Shields for the Flame of Acetylene Lamp

In some places, the men had looked elsewhere for their lamp shields, and found that the brass bases which cap the usual incandescent light bulb, when emptied of their packing and perforated at the top, could be used to advantage This arrangement is likewise pictured in the illustration. Both forms of shield can be removed easily, when not required.

While the light obtained with the use of these shields is not nearly so good as that from a lamp with the ordinary reflector, there is derived the undoubted advantage of having a steady light under varying conditions of draft, which makes this arrangement at times extremely useful to the men under ground. I also noted in the mine referred to that a number of men used these flame protectors at the working faces, apparently with good results. While it is not suggested, that this device should be used except under the conditions referred to, the idea may prove of value or convenience to some who have to contend with like circumstances.

*Mining Department, University of Washington, Seattle, Wash.

Coal Production in Africa

With the increasing development of the "Dark Continent" by railways, and the continued opening out of new mining districts to further the production of its wonderful natural treasures, the coal question becomes more and more important.

The proper solution of the problem of coal supply is much more urgent even than that of labor supply, which is so much discussed everywhere on the continent. Up to date there is only one district in Africa which has been shown to be rich in coal—Natal, where there appears to be hundreds of millions of tons. From this supply the Rand mines near Johannesburg draw what they require; and the merchant marine and the navy take coal at Durban. Not so fortunate are the other African mining regions, as for instance German Southwest Africa, where new copper lodes have recently been opened out. These mines lie near the coast; but for all that, freight rates are exceedingly high.

The inland districts, for instance the much discussed copper mines of Katanga in Belgian Congo, lie in the heart of Africa and their product must be carried by rail at least 1100 miles before it reaches the coast. The production of copper on an economical scale would be impossible if coal had to be freighted all that distance to the mines. Three hundred miles from Katanga lie the Wankie coal beds. If these can not deliver enough coal, and other strata are not opened out, the favorable development of the Katanga district will be out of the question, in spite of its great copper deposits.

This example shows plainly the importance of the coal question in central Africa. Without doubt Central Africa—North Rhodesia, Katanga, and the Tanganyika-Nyassa districts—has rich ore deposits. But the hopes now based thereon will disappear if sufficient coal is not discovered.

The Election of Mine Inspectors

By J. T. Beard

Conditions and causes that led to the enactment of the first coal-mining law in the United States. Improvement in mining shown by increased tonnage and decreased death rate in anthracite mines in Pennsylvania. Certification of mine foremen. Law creating miners' examining board and the certification of miners in anthracite mines. The anthracite mine inspectors' election law. Effect on mine inspectors, examining boards for mine foremen. How the law affects miners. The repeal of this law urgent.

Since the enactment of the law in Pennsylvania, in 1901, requiring that all anthracite state mine inspectors be elected by popular vote of the people in the several inspection districts specified in the law, the results have been closely watched by mining men in the principal mining districts throughout the United States and Canada.

Inasmuch as frequent inquiries are made by states facing a similar crisis, asking what success has attended the inauguration of this system in Pennsylvania; and in view of the fact that the enactment has never met with the approval of the state Department of Mines or the mine inspectors themselves; and since, at different times, efforts have been made, though unsuccessfully, to have the act repealed, and these efforts will be repeated at the meeting of the next legislature, it is of interest to review briefly the conditions that were responsible for the enactment and summarize some of the effects of the law.

It was the memorable Avondale disaster, Sept. 6, 1869, that shocked Pennsylvania and aroused her legislators to a realization of the immediate necessity for an adequate mining law. This resulted in the enactment of the law known as the "Ventilation Act," which, though far from being perfect, went a long way toward improving conditions and safeguarding the work of mining, by requiring the adequate ventilation of mines and providing for at least two separate openings to every mine and a thorough system of mine inspection.

Effect of First Pennsylvania Mining Law

There is no doubt in the minds of practical mining men of every type that the enactment of this first mining law in Pennsylvania, in 1870, which was, also, the first adequate law regulating coal mining in the United States, resulted in a vast improvement in mining conditions throughout the state. This is clearly evidenced by even a cursory glance at the tabulated statistics, as published in the anthracite report of the Department of Mines, 1910, p. 62. The table there given shows the number of employees, total tonnage, fatal accidents and death rate, for each year from 1870 to 1910, inclusive. We reproduce here, for handy reference, the same data for each fifth year during this period, and the corresponding averages for each five years, in this time.

The greatest apparent benefit derived from the mining law of 1870 is shown in the rapid decrease in the death rate and the large increase in the tonnage, in the first five-year period following the enactment, 1870-4, inclusive. During this period, the number of employees increased 96.5 per cent., and the production of coal 65.2 per cent. Both of these factors would naturally increase the chances of accident over 100 per cent.; but, owing to the improved conditions under the new law, the number of fatalities increased from 211 to 238, only 12.8 per cent., while the death rate per million tons of coal produced decreased from 14.85 to 10.17, or 31.5 per cent. A similar improvement, though naturally less pronounced, continued during the second five-year period, 1875-9, inclusive, when the number of employees increased 48.7 per cent. and the tonnage 19.5 per cent., while the number of fatal accidents fell to 202, in 1880, a decrease of 15.1 per cent., and the death rate for that year was only 7.22 per million tons of coal produced, decreasing 29.1 per cent., in this period.

The third five-year period, 1880-4, inclusive, fails to show the same marked improvement in mine management. The reasons for this, though to an extent problematical, are to be attributed largely to a growing indifference to the mine law, which had now been in force 10 years, and an ever-increasing demand for coal and decrease of intelligent miners and mine bosses. This latter condition forced the alternative of employing a greater and greater proportion of foreign labor in the mines and increased the dangers of operation. During this period the mine employees and tonnage increased 36.7 per cent., while the fatalities rose to 332, in 1885, an increase of 64.4 per cent., and the death rate per million tons for that year became 8.68, increasing 20.2 per cent.

Five-year Averages, 1870-1910

It is evident that any unusual occurrences, such as variable market conditions affecting the number of days the mines worked in the year; strikes or other labor conditions; mine explosions, etc., might materially modify the results for any year, as given in the first section of the above table. For this reason, the five-year averages, shown in the second portion of the table, are perhaps more representative of existing conditions. The same general increase in number of employees and tonnage per year is shown by these average figures, for the three five-year periods, 1870-1884, inclusive. The average death rate per million tons,

TABLE SHOWING NUMBER OF EMPLOYEES, TONNAGE, NUMBER OF FATAL ACCIDENTS AND DEATH RATE, FOR EACH FIFTH YEAR, 1870–1910, INCLUSIVE. ALSO, AVERAGE OF THE SAME DATA FOR EACH 5-YEAR PERIOD, IN THE SAME TIME, AND THE PERCENTAGES OF INCREASE IN EMPLOYEES AND TONNAGE

Year	Employees	Production in Tons (2000 Lb.)	Number Fatal Accidents	Death Rate Per Million Tons	Death Rate Per 1000 Men		
1870	35,600	14,172,004	211	14.89	5.93		
1875	69,966	23,402,646	238	10.17	3.40		
1880	73,373	27,974.532	202	7.22	2.75		
1885	100,324	38,232,155	332	8.68	3.31		
1890	119,919	44,986,286	378	8.40	3.15		
1895	143,705	56,948,756	421	7.39	2.93		
1900	143,824	57,363,396	411	7.16	2.86		
1905	168,254	78,647,020	644	8.19	3.83		
1910	168,175	83,683,994	601	7.18	3.57		
Period	Five-Year Averages					Percentage Increase Employees	Percentage Increase Output
1870–4	43,987	17,240,762	228	13.38	5.26	96.5	65.2
1875–9	68,019	24,701,618	222	9.03	3.25	48.7	19.5
1880–4	81,820	34,290,125	284	8.23	3.34	36.7	36.7
1885–9	110.413	41,925,038	338	8.05	3.06	19.5	17.7
1890–4	130,307	49,944,523	425	8.51	3.26	17.7	26.7
1895–9	145,275	55,340,810	444	8.03	3.09	0.1	0.7
1900–4	150,554	62,925,186	467	7.41	3.09	17.0	37.2
1905–9	169,780	80,122,004	631	7.87	3.71	0.0	6.4

for the third period, 1880-4, however, shows a decrease instead of increase, pointing to the greater frequency of fatalities toward the close of this period.

Enactment of Law Requiring Certified Mine Foremen, 1885

A growing need was felt at this time for greater competency on the part of the average mine foreman. In the same manner as the Hartley disaster, England (1862), and the Avondale, Penn. (1869), caused a reaction in favor of more adequate mining laws, so the conditions in Pennsylvania, at this time, gave rise to a popular demand for a law requiring the certification of mine foremen, which requirement became law in Pennsylvania, in 1885.

Creation of the Miners' Examining Board, 1889

In 1889, the anthracite mines were further safeguarded by the enactment of a state law creating a Miners' Examining Board in each inspection district, and prohibiting the employment as a miner, in any anthracite mine in Pennsylvania, of any person not holding the certificate of the board. This law, like that providing for the examination of mine foremen, was calculated to raise the standard of intelligence among miners; and but for the reckless disregard of the law and the dishonesty of examining boards in granting certificates to incompetent persons, conditions in the mine would have been greatly improved. Owing to the reasons just stated, however, the benefit derived from the enactment of this law was not as great as the framers of the law had a right to expect

Prominent Features of Mine Law

By the foregoing brief review, I have endeavored to draw attention to the importance of mining legislation, by calling to mind a few of the main features of the Pennsylvania anthracite law that have or should have operated to increase the safety and economy of mining in anthracite mines. It is an old saying that "Figures do not lie"; and when carefully tabulated statistics, such as those published in the annual reports of the Department of Mines, in Pennsylvania, are studied and rightly interpreted, they cannot fail to show the importance of effective mining laws.

Without going into minute details of the numerous rules and regulations intended to safeguard and control minor points in the operation of mines, I have referred to such leading features of mine law as ventilation, inspection, examination and certification of mine foremen and miners. These, each and all, have been the means of establishing a comparatively high degree of safety in the mining of anthracite coal in Pennsylvania.

The Anthracite Mine Inspectors' Election Law, 1901

There is another feature of the anthracite law, enacted in 1901, that has operated quietly to undermine and destroy, during the past decade, all that the law had previously accomplished. This enactment is the law requiring the election of the anthracite mine inspectors by popular vote of the people. The law has well been described as pernicious, seductive and destructive, as opposed to all that is wholesome, ingenuous and constructive. In his annual report for the year 1903, James E. Roderick, chief of the Department of Mines, in Pennsylvania, refers to this law as the work of "a few interested persons" who succeeded in inducing the anthracite miners, assembled in convention, to pass a resolution calling upon the legislature to amend the mining law so as to provide for the election of the anthracite mine inspectors by the people.

The reason given for this demand was that it would place in the hands of the voters, in each district, the choice of the inspector for that district and remove all cause of complaint growing out of the appointment of an inspector who might prove objectionable to the miners of the district. The reasoning was seductive; it was seemingly a just and fair proposition to allow the people to choose, by direct vote, their own inspector. Thinking men, however, saw the inevitable result of granting this demand voiced by a few men whose judgment was temporarily blinded by the rehearsal of some supposed wrongs ascribed to an alleged objectionable inspector. The sequel has proved the unwisdom of the law, and today the demand among intelligent people for its repeal is even more urgent than that for its passage ten years ago.

Effect of the Law on Mine Inspectors

The mine-inspection service of the state is a thankless service. The men charged with its duties are officers of the law, whose business it is to enforce its provisions. To transgressors and violators of law, these men are often "objectionable." To place the choice of the inspector in the control of the voters of a district where the votes are practically dictated by a few men who desire to be unmolested and to make their own interpretation of the laws to suit their individual cases, would be to surrender the law to its violators.

What is law, when the officer charged with its execution is helpless in the hands of would-be violators of law? What is mine inspection when the inspector must close his eyes as he goes through the mines and seal his mouth when he comes to the surface? But this is the logical result and what must be expected under the anthracite mine inspectors' election law. The inspector becomes the servant of the officials of the mines he inspects, instead of the servant of the people and an officer of the law.

On the inspector's side, the effect of this law is no less baneful. His conscience is stultified, his dignity degraded and his usefulness to the state forfeited In some instances the inspector, in the anthracite region, has proved a mere figure head. It is true he has collected some valuable statistics of mining and drawn his salary. In other instances he has even made suggestions, some of which may have been carried out. Few indeed are the cases where there has been any serious contention on the inspector's part, who has generally refrained from making suggestions that would be at variance with the company's wishes.

Effect of the Law on Examining Boards

One of the most harmful effects of the mine inspectors' election law is the influence exerted by the other members of the examining board for mine foremen to force the inspector into line, in reference to the desired recommendation of a candidate whose examination before the board has shown him to be wholly incompetent to hold the position of mine foreman, but whose political influence, backed by the expressed wishes of his company, demands recognition by the board. The mine inspector is an *ex-officio* member of the board of examiners for mine foremen, the other members of the board being two miners and one mine operator, superintendent or owner. The inspector is generally in a position better qualified to judge of the competency and fitness of a candidate to fill the position of mine foreman than any of the other members of the board. In most cases, however, he is compelled to set aside his own convictions and join with the rest in recommending the candidate and signing his certificate of competency. The refusal to do this would probably jeopardize his chances in the next election, and no one realizes this better than the inspector himself.

Effect of the Law on Miners

Instead of this law working to the advantage of miners, as they had been led to believe it would, by placing in the hands of each miner a vote for the man of his choice, it has operated much to their disadvantage. In many instances the miner's vote is not his own but is cast in compliance with the dictation of bosses, which limits his choice of inspector to their selection of the man for whom he must vote.

The working of the law with respect to examining boards for mine foremen has proved a menace to the safety of mines, by the certification of many in-

competent men for that position, by reason of which the lives of miners have been endangered.

The same law has also proved a hindrance to many ambitious, deserving miners who have studied to fit themselves for foremen and assistant foremen. Their knowledge of theoretical and practical mining will, in many cases, surpass that of the man who secures his certificate by other means than proving his competency in examination. Too often the worthy and competent miner is pushed aside by one whose only hope is through the employment of dishonest means to secure the necessary certificate.

Repeal the Mine Inspectors' Election Law

There is probably no law on the statute books of Pennsylvania, the repeal of which is more urgently demanded by intelligent mining men of all classes, from the miner who advocated the law, to the mine inspector who has most keenly felt its burden. Let the miners, who are responsible for the enactment of this election law, do their part to wipe it off the books, recognizing what is a fact, that it is a disgrace to honest mining, the work of grafters and wire pullers, and subserves no good purpose but rather is a menace to life and property and a hindrance to the merited advancement of ambitious and competent miners.

Appointment of Mine Inspectors

Throughout the bituminous districts of Pennsylvania, as in almost every mining state, the appointment of mine inspectors is general. In most cases, the governor is clothed with the appointing power and the term of office varies from two to four years. I have suggested, at different times, the feasibility of the delegation of the appointment of mine inspectors to the judges of the district courts in the respective inspection districts who should also properly appoint the boards of examiners for mine inspectors, and base their selection of mine inspectors on the reports of the examining boards. The appointment of both the examining boards and the mine inspectors should be, confessedly, as far removed from politics and the influence of wire pullers as it is possible to have them.

The work of mine inspection is a most important work. It is and should be a subsidiary part of the state government and subject to its control, as far as its work is concerned. Owing, however, to the peculiar relations that the inspector must bear to the mine operator and miner, as custodian of the mine law, his position should only be assailable through the courts, by process of law.

There are strong reasons why the appointment of mine inspectors should be for a long period of years, say, 20 or 30 years, or good behavior with a time limit. One of the most important of these reasons is the fact that a good inspector becomes more efficient and valuable each year. His growing familiarity with the mines and district in his charge and his knowledge of local conditions and requirements make his service more effective each succeeding year. He knows each mine as a mother knows her child. He understands better the whims and habits of both operators and men as time improves his acquaintance. A short term of office and the frequent change of inspectors is both troublesome and costly. Owing to the lack of a full appreciation of conditions, and in part, to the desire of a new man to do something worth while and to make his presence felt, changes in the mine work or equipment are often urged that a longer acquaintance with the mine would show unnecessary and perhaps even harmful. The need of longer term appointments is more urgent in mine-inspection work than in any other calling, owing to the expense and danger incurred by ill advised changes in methods or equipment, in and about mines.

A careful consideration of these and other facts, in the same connection, should impress any thinking man with the inadvisability of the mine inspectors' election law. But, in closing, I would ask, if such an election law is necessary or advisable in the anthracite district of Pennsylvania, why is it not likewise advisable to enact such a law for the bituminous districts? What difference of conditions or requirements exists between these two districts, in the same state, that the anthracite inspectors must work for their reëlection at the polls, while the bituminous men are reappointed on their record. Much valuable time is lost to the state and the work of the inspector hampered when he is forced into politics and must exert himself for weeks in the endeavor to secure his reelection at the polls.

Some Drafting Accessories

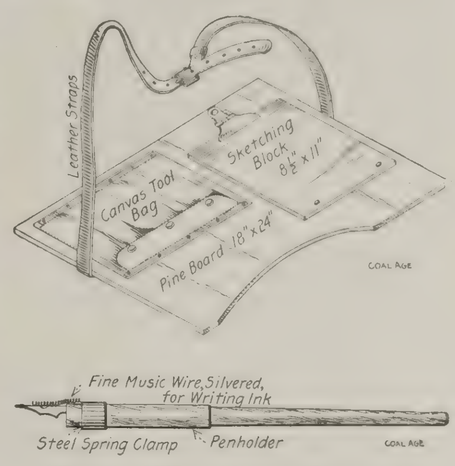
The following notes, from the *American Machinist,* will doubtless prove of interest to the members of engineering profession among the Coal Age readers:

A Convenient Sketching Device

The accompanying diagram illustrates a convenient sketching device. It consists of a small drawing board about 18x24 in. It is intended that when the board is in use it will be hung from the shoulders of the draftsman. For this purpose leather shoulder straps are attached on each side at a point a little beyond the center. When the device is not in use it may be allowed to hang vertically from the shoulders and the user is but little inconvenienced in moving or climbing about. The straps are adjustable as to length. The side of the board nearest the user is cut away slightly to conform to the natural form of the body.

The board is provided on the right with a sketching block or pad, which is securely held by means of a spring clip. Two small pegs at the lower end fit into corresponding holes in the block to prevent it from slipping about. It is intended that the sketches when completed may be removed from the block and inserted in a loose-leaf book cover.

On the left side the board is provided with a canvas tool bag which is fastened to the board by means of thin metal strips at each end. The canvas flap may be fastened down by means of straps and buckles or snap fasteners as desired. The bag is divided into compartments in which the draftsman may keep his instruments.



Sketch Board and Reservoir Pen

When taking measurements the board may be laid to one side if necessary in order that the draftsman may move freely about. A sheet of celluloid may be kept under the hand to protect the sketch from dust and grease.

Another Reservoir Pen

I have been using a reservoir pen for five or six years; I think it better than any other type I have ever seen described. The pen I refer to has the advantage of being equally useful for writing or india-ink work. The flow of ink to the point can be regulated by sliding the coil up or down on the penpoint. While the coil can be made of steel music wire for india ink, I made mine of silvered banjo strings, so as to use them with any kind of ink. The penpoint can be removed by sliding the coil up out of the way.

To Determine Pillar Thickness

The following rule has been suggested for determining the thickness of pillar necessary to avoid squeezes, and protect an entry from the first room in the panel: Take 1 per cent. of the depth of the seam in feet, add five and multiply this sum by thickness of seam and you will have the necessary pillar thickness.

The Pit Boss

The pit-boss stood at the Pearly Gate
His face looked worn and old,
He meekly asked the man of fate
For admission to the fold.

"What have you done," asked Peter kind,
To seek admission here?"
"Oh, I used to boss a coal mine
On earth for twenty year."

The gate swung open sharp
As Peter touched the bell.
"Come in, my lad, and take your harp
You've had enough of Hell."

—William Harkes, in "Fuel."

Double Tipple for Colonial Coal Co.

By W. T. Griffith *

Conditions which attended the development of the Colonial Coal & Coke Co.'s property, near Prestonsburg, Ky., were met by the construction of a double tipple, which embodies several interesting features. The tipple and also the local power plant are here described.

While the property controlled by the Colonial Coal & Coke Co., near Prestonsburg, Ky., lies adjacent to the railroad and the Big Sandy River, its frontage is a bluff 30 to 60 ft. high, except for a small steep drain known as Kelse Hollow, which empties into the river near the middle of the track; and it is in this hollow that the tipple and power plant are located. The seam of coal that is here being worked lies at tipple height above the railroad. Two mines have been opened, one on each side of the hollow, and tracks from each opening run to the tipple, which is located midway between them.

Two-inch Bar Screens

After the introduction of machine mining in this locality, it was found that the native miners, being used to shooting from the solid, persisted in using as much powder after the coal had been undercut as they had previously been accustomed to employ, with the result that an excessive amount of slack coal was produced. On this account, the tipple was provided with 2-in. bar screens, and the miners are now paid on the basis of the amount of coal which passes over these bars. That the introduction of the 2-in. bar screen has had the desired effect, is shown by the fact that, whereas, formerly 30 per cent. of four-inch lump was exceptional, now 40 to 50 per cent. of four-inch lump and 20 to 25 per cent. of egg are commonly obtained.

In designing the tipple for this operation, another difficulty had to be solved. It was necessary to be able at any time to change quickly from making sized coal to loading run-of-mine, or *vice versa*. This was accomplished by building a double tipple, the south side of which is for screened coal and the north side for run-of-mine. On the tipple floor, Fig. 1, the tracks are so arranged that, by throwing two levers, four switches are operated which effect the necessary changes in the movement of the cars from the two openings. Thus, if it is desired to load screened coal, the switches A and A_2 are left open for a straight run to the screen dump, while the switches B and B_2 are closed to provide a free passage for the empties to the empty track. If run-of-mine coal is to be loaded the position of these switches is reversed.

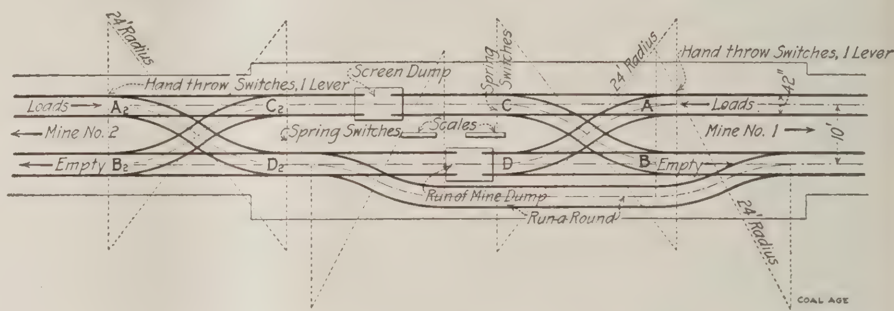


FIG. 1. TRACK PLAN, SHOWING TWO DUMPS AND ARRANGEMENT OF SWITCHES

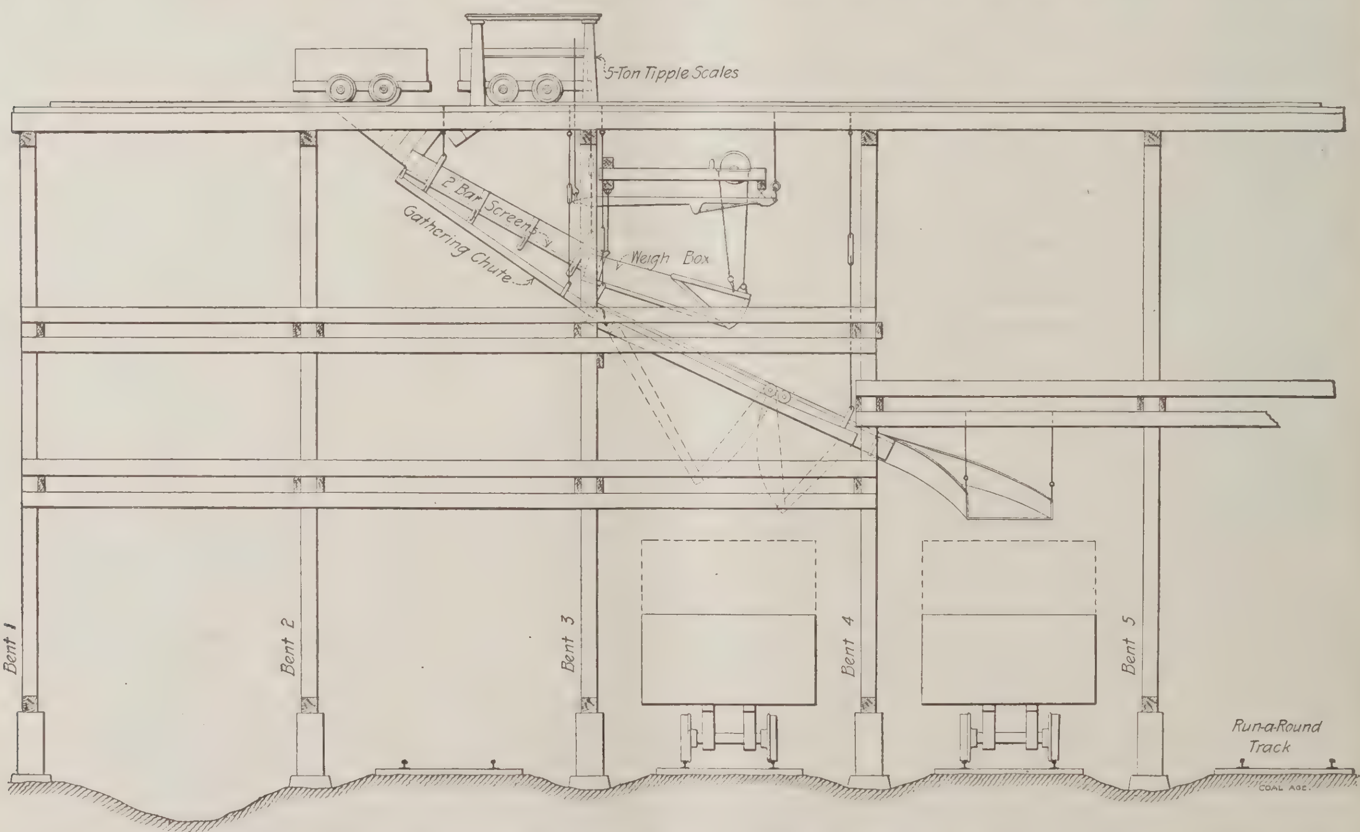

FIG. 2. SIDE ELEVATION, SHOWING MINE-RUN DUMP AND LOADING CHUTES

*Civil and mining engineer, Pikeville, Ky.

The switches C and C_2, also D and D_2, are held in place by springs to give a free run to the empty cars. They are pushed open by the wheel flanges as the loads pass through and always stand in the same position whichever side of the tipple is being used. In order that motors and machines may be taken from one mine to the other, a run-around track is provided at one side of the tipple.

Loading Facilities

While making screened coal, it often happens that a rush order for a car of run-of-mine comes when the lump track is blocked with a partly loaded car, althought the egg-coal track can be cleared at once. In order that either track may be used in a case of this kind, a drop-bottom has been provided in the run-of-mine chute, which, on being opened, allows the coal to pass into a car on the egg-coal track, and when closed carries it over to a car on the lump track.

In loading run-of-mine, coal from the pit cars is dumped onto the 2-in. bar screens, and the fine material that goes through is taken by a gathering pan to the main loading chute, while the coal that passes over the bars runs into the weigh box, and after being weighed, is dumped into the main chute.

On the screened coal side of the tipple, is another set of bar screens, and a gathering chute. The fine coal passing through the bars goes to the upper end of the slack and nut shaker, while that passing over the bars, after being weighed, is dropped onto the middle of the same shaker. The upper shaking screen is 5½ ft. wide, and the lower shaker is 6 ft. wide, there being a 3-in. drop from one to the other. The screen plates of both are made in sections 4 ft. long and are easily removed and changed. Two sets are provided for each shaker, so that any of the combinations shown in Fig. 3 may be made.

The bottom of the bin or hopper under the egg-coal screen, is pitched in the direction of the loading track, and constitutes a lip screen, with ¾- by 1½-in. slotted openings, so that small coal, caused by breakage in traveling through the screens is taken out and sent to the slack car by a screw conveyer.

Since the tipple was designed the railroad company has increased the height of some of its cars. In order to clear the brake wheels of these, a drop basket, which was built for the lump track, has been set aside and a swinging chute substituted. This is hinged loosely on a piece of 2-in. shafting, and by slipping it along the shaft, to clear the shaker, it can be raised by the counter weight to pass the brake wheels, after which it is returned to place, the whole operation taking about two minutes.

The shaking screens have a 9-in. throw, and are run at 100 r.p.m. These, together with the screw conveyer are driven by a 25 hp. General Electric motor. With the exception of the screw conveyer and the bar screens, all the machinery, including shakers and chutes was furnished by the Stevens-Adamson Manufacturing Co. from my designs.

The Power Plant

The power house at this mine is equipped with a single 150-hp. Kingsford Scotch-marine-type boiler, and a 100 kw. Curtiss-turbine generator set. Provision has been made for installing two more boilers and additional generators as future development may require them. The water supply for this plant is taken from the Big Sandy River by a deep well pump, having a capacity of 100 gal. per min., and is pumped to a reservoir on the hillside 140 ft. above the railroad. There is thus furnished a much larger amount of water than will ever be needed for power purposes, the idea being, however, to secure adequate fire protection as well. As an auxiliary supply, a small dam was built across the hollow, and if necessary, the boilers can be supplied from this source by a steam injector.

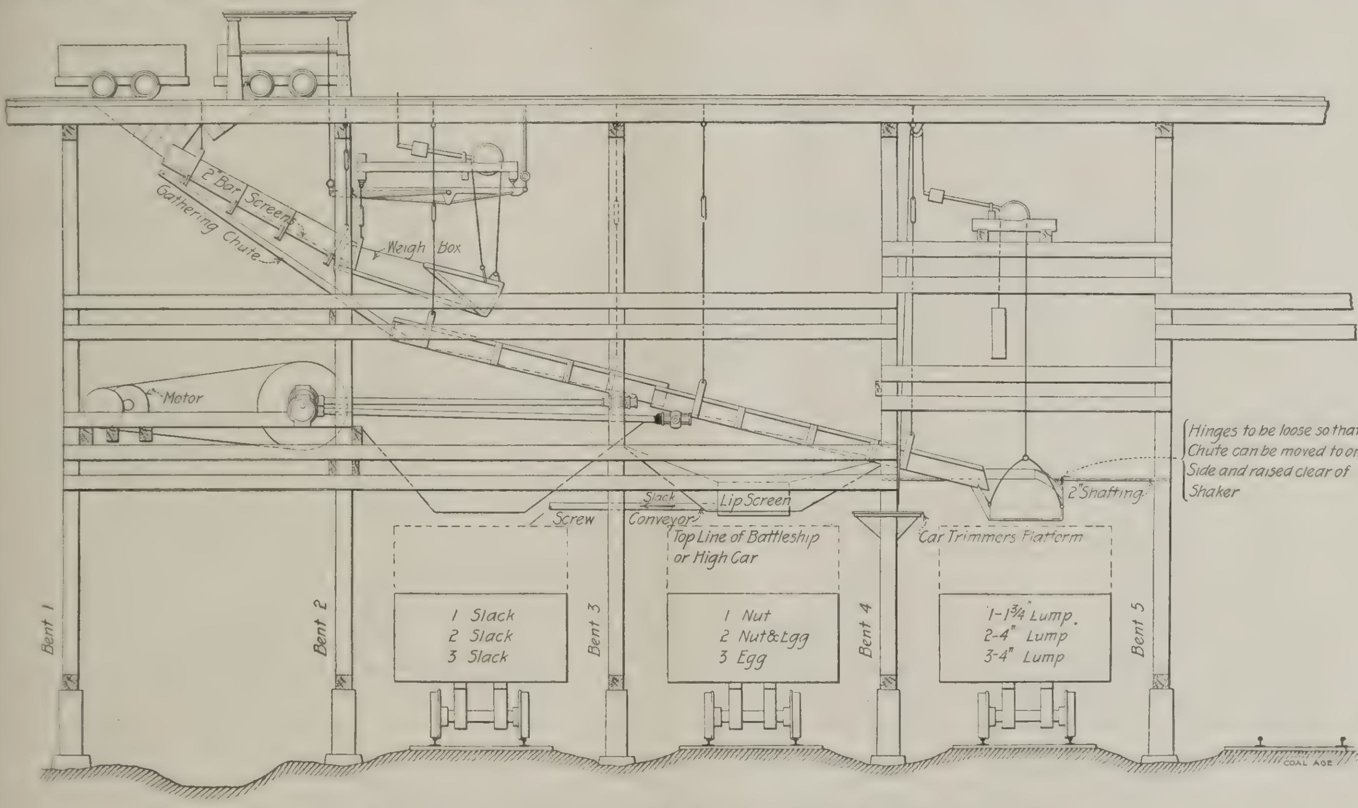

Fig. 3. Side Elevation, Showing Screened-coal Portion of Tipple

---

One of the largest producer gas units in the world is located at the Berchenwood colliery, Kidsgrove, England. The plant is equivalent to 32,000 hp., gasifies 320 tons of fuel per 24 hours and comprises 13 special Mond producers fitted with arrangements for the mechanical removal of ash. Waste shale, low grade coking coal, bituminous slack, washery refuse and belt pickings are used for gas production.

The Susie, Wyoming, Explosion

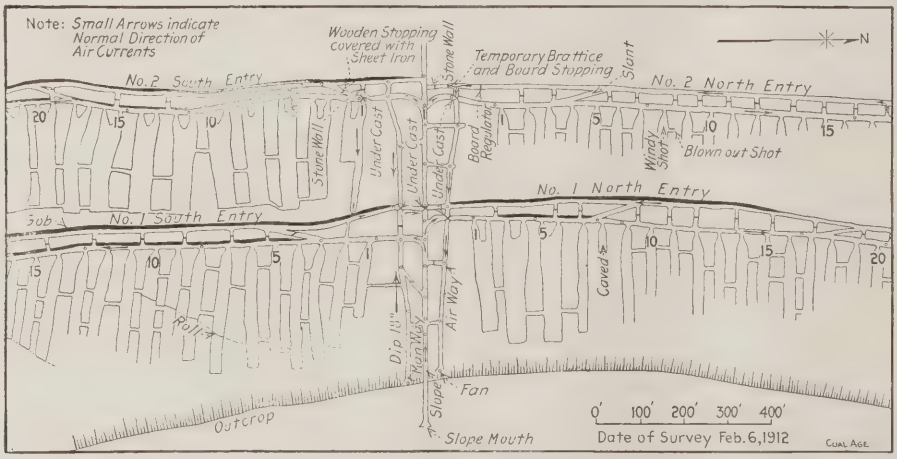
By C. S. Beach*

The final conclusions relative to the cause and effect of the Susie explosion are presented herewith. The accident is another glaring example of the striking ignorance and carelessness of some of our miners today.

An explosion occurred in No. 4 mine of The Kemmerer Coal Company, situated at Susie, about four miles north of Kemmerer, Wyo., shortly after 4 p.m., Jan. 20 last, killing 5 men, and injuring 20 more. This mine was opened for operation in the fall of 1907, and the present development consists of a main slope, manway, return airway, and two double entries to the north and south. The approximate output is 500 tons per day of 8 hours.

System of Mining

The double entry system with the room-and-pillar method of mining is used. The strike is nearly north and south, the seam dipping about 18° to the west, and it is practically 6 ft. thick. The bottom 12 to 14 in. of coal is comparatively soft throughout the mine, and is separated from the top coal by a band of clay varying from nothing up to 6 in. thick. A cap rock varying from nothing up to 20 in. thick comes down in places.



Portion of the Kemmerer Coal Co.'s Mine No. 4, at Susie, Wyo.

The haulageways and air courses are 6x10 ft., except in places where the cap rock is excessive, when they are driven wider and the rock gobbed on the lower rib. The single rooms are driven on 50-ft. centers, 25-ft. room and 25-ft. pillar. The double rooms are driven on 30-ft. centers, 40-ft. room, with about 30-ft. pillars. The mine is ventilated by a 4-ft. belt-driven Stevens fan, running 490 revolutions per minute, exhausting. Concrete undercasts and rock wall main stoppings are used.

In places the mine is naturally damp, the water coming from the roof, and from the parting between the top and bottom coal. Sprinkling is done by means of a water car, and pipe line connected both with the mine pump and outside water supply. Black powder fired by fuse and squib is used entirely, and shooting off the solid is the custom. No gas has ever been discovered in the mine up to the present time.

The Explosion

The evidence at the coroner's inquest proved beyond doubt, that the origin of the explosion was in No. 8 Room, on the No. 2 North Entry. It is believed that the miner in No. 8 Room fired two shots, both in the bottom coal near the clay parting, one at the face near the center of the room and one in the unfinished crosscut, leading to No. 9 Room, a little above the center.

The shot in the crosscut blew out without doing any work, and the shot at the face of the room broke from the back of the hole through a slip, and must have been very windy, as little of the powder's force was expended in doing work. These shots were so placed that the resulting forces crossed each other at nearly a right angle, and the evidence gathered in the room shows the same.

When the explosion reached the main entry it divided, a part going inside and doing little damage. Five men at the new room, No. 15, felt the force, but no flames were seen. The force going towards the slope evidently split at the mouth of the slant, enough going into back entry to destroy a temporary canvas brattice across the slant, and a board regulator 4 ft. inside the return air course.

The force again split on reaching the main slope, part crossing into the No. 2 South and blowing parts of a board and sheet iron stopping in the first slant, about 300 ft. in the back entry. Part of the force wrecked a newly constructed stone stopping about 18 in. thick, just off the main slope in the No. 2 North Back Entry, forcing same towards the return airway, while an old temporary board and brattice stopping 30 ft. inside of the stone stopping was left intact.* There was no evidence of the force of the explosion having gone to the face of the slope.

From the second entries the force of the explosion traveled up the slope, going into both the No. 1 North and South Entries for short distances. Although considerable smoke came out of the main slope, and manway, there was no flame. The force of explosion in the return airway was sufficient to throw the belt off the fan engine and raise slightly the roof of the fan conduit, made of sheet iron riveted to 20-lb. rails, and covered with earth. The fan was not damaged in the least and was running probably within 8 to 10 minutes after the explosion.

Effects of the Explosion

Men on and near the slope, at the partings, were severely burned on the exposed parts of their bodies, and men between No. 8 Room, on the No. 2 North Entry and the slope, were also burned. Approximately 120 men were in the mine at the time of the accident.

The only fire or flame seems to have been such as was caused by the ignition of the dust, pulverized by the blown-out shots, and such as would naturally exist from the breakage of coal at the face when the shots were fired. The explosion was purely local, due to the fact that the mine was practically free from such dust as generally serves to extend such explosions.

That No. 4 mine was not in an explosive condition, is proved by the fact that the flame was confined to such a small area. The advantage of concrete undercasts and good stone stoppings was fully shown here by their ability to withstand the force of the explosion. A careful examination of the mine showed very little damage done.

Many individual acts of heroism were performed by the employees of No. 4 mine as well as men from adjoining mines in rescuing the injured and recovering the dead.

*Assistant superintendent, the Kemmerer Coal Co., Kemmerer, Wyo.

*For a detailed discussion of this strange phenomenon, see Coal Age, Vol. 1, p. 650.

Expropriation of British Mines

Special Correspondence

The British government, by accepting the principle of a minimum wage scale and incorporating it into an act of Parliament, has taken a definite step toward the expropriation of the coal mines of the United Kingdom. The strike of the British miners has clearly and abundantly demonstrated that the integrity of the empire politically and socially lies within the power of a million of mine workers. There is no exaggeration in this statement. The realization of that fact came home to every man, woman and child in Great Britain and Ireland during the past five or six weeks, to some with actual suffering and to others with a haunting apprehension of suffering to come.

It seems to me as I interpret the future by the light which this historical labor revolt and its consequences affords, that another strike on a similar scale would be fatal to the industrial, financial and international supremacy of England. A repetition of such a strike she must obviate at all cost. How can she do it? In my opinion, there is only one way in which it may be done, and that is by expropriating the coal mines of England, Scotland and Wales. But it will be said that such a measure is an acknowledgment of the necessity for the adoption of socialistic principles. Not at all. But even if it is, in my judgment, the fact and its consequences must be accepted to avoid a greater evil, if the power of the British miner to injure the empire does indeed constitute an evil. Englishmen are not afraid to face the logic of realities. If it is necessary, or if they deem it necessary, they, without the slightest hesitation, will expropriate the mines rather than face the alternative of industrial anarchy and national distress.

The Tory or Conservative press of Great Britain is today demanding whether forty-two millions of people must be at the mercy of one million men who happen to be engaged in an essential industry. The British Tory press declares that the Liberal government has raised a Frankenstein which it cannot conjure. Of course, this is more or less party politics; but it expresses a truth which cannot be gainsaid. As matters stand, forty-two millions of people *are* absolutely at the mercy of one million of mine workers. The acceptance of a minimum wage scale as a national economic principle has not altered the situation; it has only to a certain extent modified it. Neither the British miners nor the British operators seem to be satisfied with the establishment of district boards as regulators of the minimum wage scheme. The miners have realized their omnipotence, and what they accomplished yesterday with such ease they can accomplish tomorrow for some other purpose.

Great Britain has to maintain an enormous fleet of battleships, not to speak of a stupendous mercantile marine. The one is complementary to the other. Without the mercantile marine, Great Britain would have little or no need of her enormous fleet. She must maintain both at the height of their efficiency. She cannot do this without coal. It may be accepted as established that for England, at least, local strikes are bygone incidents, and that for the future under the auspices of the Miners' Federation all strikes in the coal fields of Great Britain will be national in extent and a unit in intensity. I am satisfied that before a British government, no matter which party is in power, permits another strike on the scale of that which has just lately closed, it will come out plainly and squarely for the expropriation of the mines, and that in doing so it will have behind it the solid and enthusiastic support of the people of the country. I do not think that that consummation is very far off. There is nothing really new in this proposition.

Twenty years ago the Irish landlords were as firmly entrenched in the possession of their estates as the colliery proprietors are today in the possession of their mines. The social and economic upheaval which ended with the expropriation of the hereditary possessions of the Irish country gentry with adequate compensation, meant as much to them, and to their country and no more than a change in ownership of the mines of Great Britain will involve to the operators and people of the British Isles. Of course, national transformations of this kind do not take place in a day. It takes all the statemanship, all the financial genius of a nation to effect these things without suffering even more revolutionary upheavals. But the industrial situation in Great Britain is inevitably heading that way.

A general strike is more devastating and disconcerting financially than a war, even a civil war. In war the arteries of national commerce remain open, and often are more active than they were before, or are in the succeeding years. The national life is not totally paralyzed, as it often is in a general strike among miners or railroad employees.

But it may be asked whether the nationalization of the mines or the railroad would prevent general strikes. This is a question into which it is impossible for me to enter here. A national strike in a national industry is simply rebellion, and rebellion is so contrary to social unity that it is but rarely found in any country and it seems unlikely that the British workman would favor it.

Using Ontario's Peat Bogs

It is announced by the Mines Department of the Canadian government that the associated manufacturers at Brantford, Ont., have become so convinced that the air-dried peat method employed by the mines branch can be made a commercial success that, according to U. S. Consul H. A. Conant, they have contracted with the government to continue the work at Alfred, Ont., and will spend over $50,000 of private capital in trying to improve peat machines. This action was decided on only after a thorough investigation. The machine to be used will have a capacity of 60 to 80 tons per day, as compared with the 30 tons the government turned out.

The government experimental plant at Alfred exhibited samples of machinery and of peat ready for market at the Ottawa fair. A thousand tons of peat were made up, which was sold at $3.25 a ton. It burns to a fine ash, there being pracically no residue, and is much cheaper than coal.

The results of the Dominion government's experiments in the production of fuel from the peat bogs in Alfred Township, Prescott County, have been so successful that the Canadian Pacific Ry. has opened negotiations with the government for the purchase of these bogs. Should the railway company secure the property, it is understood that the output of prepared peat will be greatly increased.

There are vast bogs in many parts of Ontario, and success in the present instance will be apt to start operations in many places, the more so, because of the scarcity of wood and the high cost of coal.

Distinguished German Visitors

A small committee, consisting of directors of the German Museum in Munich, holding high offices in their country, has come to the United States. The visitors are His Excellency Count Podewils, late Prime Minister of Bavaria, Dr. von Borscht, Lord Mayor of Munich, and Dr. von Miller, Councillor of the State.

The mission of this committee is to bring the German Museum into closer touch with institutions in the United States, devoted to the history of technical science. Having only a limited time at their command, its members would naturally like such Americans as sympathize with their mission to come forward, with a view to facilitating an early communication.

Coal Age therefore suggests that any of our readers who are able to give information, or wish to communicate with the committee, send their addresses to this paper, to be passed on to the German visitors as soon as possible.

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Anchoring New Bolts in Old Foundation

It is sometimes necessary to change an old foundation to accommodate a new arrangement of equipment, when, for instance, low- and high-pressure steam cylinders are compounded to increase the power of an engine. Whenever it is necessary to set an anchor bolt in an old foundation, the difficulty may be met in one of two ways, says R. B. Dale in *Power*.

In the first method a hole is drilled in the concrete slightly larger in diameter than the bolt to be used and to the proper depth. A bolt is then prepared by cutting a slot in one end lengthwise of the bolt and about 6 or 8 in. long. This slot is then fitted with a wedge of hardened steel held in place by a pin of copper or other soft metal. The bolt is lowered into the hole and struck several hard blows on the upper end with a heavy hammer. This shears the soft metal pin and drives the wedge into the slot, thus enlarging the diameter of the bolt at the lower end. The bolt is then grouted into the hole and the nut is tightened to complete the work.

In the second method a hole is drilled for the bolt as before. A second hole is then drilled laterally through the side of the masonry to meet the first hole and this is enlarged sufficiently to take the standard anchor plate. The work is completed in the customary manner, precautions being taken to grout the anchor plate to a firm bearing in the old concrete. The first method is cheap and simple, although there is no certainty as to what happens in the bottom of the hole. The second method, while more troublesome and expensive, is the more reliable and should be used on the more important work. It gives the bolt almost as secure a hold as if the foundation had been built around it.

China as a Coal Producer

By Thomas T. Read

The coalfields of China are largely in the interior and consequently but little opportunity exists for transportation of the product. Nowhere are opportunities for mining more favorable and nowhere are they more neglected. Probably as much coal exists in China as in the United States. Sulphur is usually in low percentage, but the phosphorus content is sometimes excessively high.

Coal is easily the first of the mineral resources of China, both in the extent of its deposits and in its development. A conservative estimate of the present production is 15,000,000 tons annually. The casual visitor to North China, where the winter climate is rigorous, seeing the children of the villages, armed with rake and basket, engaged in collecting every scrap of vegetable material that can be utilized as fuel, is likely to wonder why coal is not more generally used. The reason is not hard to understand: in many regions the low cost of labor, the high cost of transportation, and the low scale of living put coal beyond the reach of the people. It is probably safe to estimate that one-half the cost of the food of an ordinary workman is chargeable to the fuel used in cooking it, and where the otherwise unemployed children can be sent out to gather grass and pull up the roots of the larger cereals, such as corn and *kaoliang*, there is little market for coal, except for industrial purposes. Near the mines, where coal is abundant and cheap, it is freely employed. The development of railroads, steamships and industrial plants will not only create a greater market for coal, *per se*, but, by raising the scale of living through the higher wages paid for labor, will increase the consumption of coal for household purposes. The annual consumption of coal in the United States is approximately 3.5 tons per capita per annum; the consumption in China figures roughly only one-twenty-fifth of a ton. An approximate estimate of the present coal-production in China is given in Table I.

*Formerly professor of metallurgy, Imperial Pei-Yang University, Tientsin, China.

Note—Read at San Francisco meeting of the American Institute of Mining Engineers, October, 1911.

Total	6,140,000	5,850,000	1,150,000

Total production of all kinds of coal, 13,140,000 tons per annum.

The sketch map, Fig. 6, shows in general the coal areas of China. The dark spots in Fig. 7 show where coal has been uncovered in Manchuria.

The coals of China are as varied in quality as those of the United States, but this difference should be noted: the amount of lignite is comparatively small, and the proportion of anthracite to bituminous coal is larger than it is in the United States. Willis has estimated that the anthracite resources of Shansi and the adjacent fields are practically equal to those of Pennsylvania. If this is in error it is probably upon the safe side, and the total coal resources of the Chinese Empire seem likely, upon careful mapping, to compare favorably with those of the United States.

MANCHURIAN COAL

In Manchuria, one large mine is now in operation at Fushun. This field, seen just above the word "Mukden" on the sketch map, Fig. 7, has been described in detail, so nothing further will be given here than the statement that the coal is sub-bituminous and of excellent quality. The mines, owned and operated by the South Manchuria Ry., had a production in 1910 of 830,328 tons, and are expected to reach 1,000,000 tons per year when the second of the two pairs of deep shafts (18 and 20 ft. in diameter) are in full working order. More recently the mines at Pen-hsi-hu, on the Antung-Mukden Ry., have been developed. The chief engineer at Fushun stated, in 1909, that the Pen-hsi-hu coal is friable and semi-bituminous, occurring in Jurassic strata, and not of especially good grade, but more extensive development may have disclosed seams of better quality. The same remarks will apply to Sai-ma-chi; owing to its distance from the railroad no very serious attempts have been made to develop these workings. All mines in the South Manchuria Ry. zone are to be developed jointly by Japanese and Chinese.

Just east of Kwan-cheng-tze, coal similar to that at Fushun occurs in several places, and though the attempts at working have not been very successful as yet, the seams at this place are likely to become of great importance, as the branch railroad to Kirin cuts directly across them. West of the Liao River, a valuable and important field is said to exist, but I have not visited the locality and have no definite knowledge of it. Some time since, the Imperial Railways of North China attempted to exploit some seams of a true lignite a short distance north of the Great Wall, but they proved to be of too poor quality. Other localities where coal occurs are Yentai and Wu-hu-tsui, but the production is unimportant. As the workable coal in the Fushun field has been estimated at 800,000,000 tons, Manchuria is well supplied with coal. But the Manchurian coals are very friable, furnishing but a small proportion of lump size, and no good coking coal has yet been found.

Chili, which immediately adjoins Manchuria on the southwest, and is the metropolitan province, is now the most important producer of coal.

The lignite and bituminous coal of the Jehol district is produced by native methods, the nature of which can be inferred from the photographic views, Figs. 4 and 5, taken in the Western Hills. The Kin-Han (Peking-Hankow) railway district anthracite field and the Peking-Kalgan railway district field are northern and southern portions of one field, lying a short distance west of Peking. Hoover & Woo have described the Chinese Engineering & Mining Co.'s mines, at Tongshan and Linsi, in detail. These are the largest and most important coal mines in China. They are owned by an Eng-

FIG. 4. MOUTH OF A TYPICAL CHINESE COAL MINE

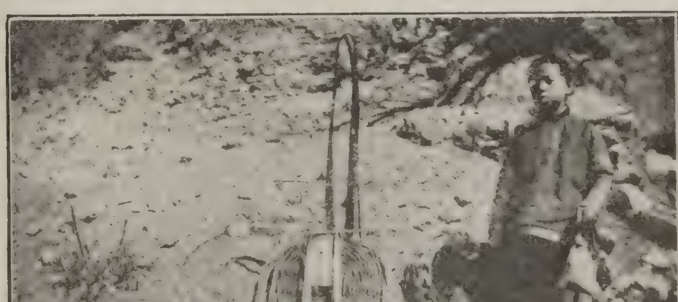

FIG. 5. IN CHINA, BASKETS REPLACE THE MINE CAR

lish company, but it has been proposed by the gentry of the province that the concession be purchased by the provincial government. Since the descriptions were written, the mines have been much developed and improved. They produce nearly all of the 1,400,000 tons, estimated in Table III, as the semi-official Lanchow mines, in the same field, have only recently been started and, though well equipped, seem unable to operate at a profit. The net return of the Chinese Engineering & Mining Co. mines for the year ended February, 1910, is given as $1,184,871. The Ching-Hsing mines, on the railroad from Shih-chia-chuang to Tai-yuan-fu, are worked under German supervision, and have both Chinese and German capital. The production in 1910 was 150,000 tons. The Lincheng mines are operated to supply the Kin-Han Ry. with fuel, and are under the supervision of K. Y. Kwong. They have an output of 800 tons per day.

Shantung Coal Fields

In Shantung, coal occurs in many places, but the larger part of the production comes from the mines owned by the Shantung Bergbau Gesellschaft, at Poshan and Fang-tze; 252,816 tons of anthracite coal having been produced at the former place in 1910, and 230,064 tons of bituminous at the latter. These mines have washing plants. Some difficulty has been found in working, owing to the faulting and disturbance of the beds, and the native papers say that there is little profit in their operation. In this, as in every other coal field in China, there is a large amount of native mining upon a small scale. Farther to the southeast, near Yi-hsien, is a bituminous field which is said to be larger and better, but which I have not visited. The production of the native mines is already important. A large native company, called the Chung Hsing Kung Ssu, has been formed, machinery procured from Germany, and a railroad constructed from the mines 35 miles to the Grand Canal. This will probably be extended to connect with the Tientsin-Pukou R.R., and when the latter road is in operation, the production of coal in this district should become important.

As Much Anthracite in Shansi as in Pennsylvania

Much has been written concerning the coal fields of Shansi. These anthracite seams are the most striking coal beds in the empire, as they are so thick, so little disturbed, so well exposed and so widely distributed, having an extent of nearly 200 miles north and south, and from 25 to 30 miles east and west. There are several seams, one of which is especially thick and persistent. Richthofen estimated the area of the field as 13,500 square miles, and Drake estimated the average workable thickness of the seams as 22 ft. As the beds are frequently but slightly inclined, this corresponds to a yield of over 22,000,000 tons per square mile of workable area, so it is safe to estimate that the anthracite resources of this part of China are at least equal to those of the United States.

TABLE III. PRODUCTION OF COAL IN CHILI PROVINCE FOR 1909

District	Tons
Lignite	
Jehol district coal-fields	150,000
Total lignite	150,000
Anthracite Coal	
Kin-Han railway	600,000
Peking-Shanhaikwan railway	50,000
Peking-Kalgan railway	170,000
Total anthracite	820,000
Bituminous Coal	
Peking-Shanhaikwan railway	1,400,000
Kin-Han railway	410,000
Peking-Kalgan railway	40,000
Lan-Ho and Jehol	100,000
Chow-yang-fu	140,000
Total bituminous coal	2,090,000

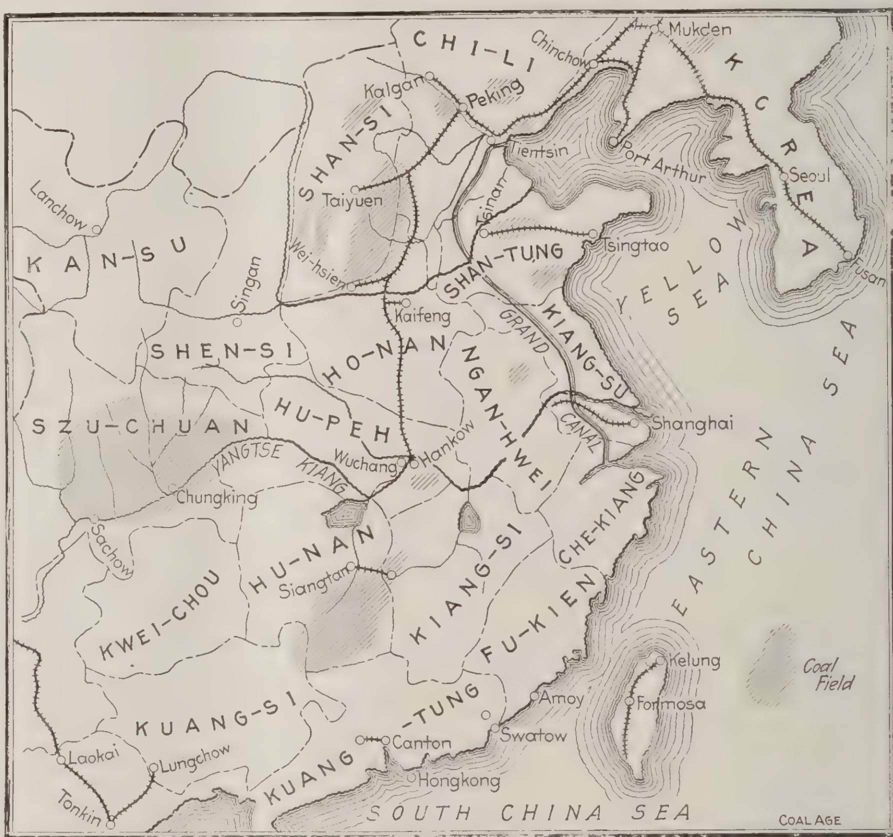

Fig. 6. The Chinese Coal Areas and Railroads

Shansi also possesses considerable resources in bituminous and semi-anthracite coal, which is produced both to the east and west of Tai-yuan-fu.

Shensi, Kansu and Ssu-chuan

In Shensi, which adjoins Shansi on the west, extensive coal fields are known to exist, and Richthofen thought that the bituminous fields to the west of Tai-yuan-fu were of equal extent and importance to the anthracite fields on the east. This is possibly too optimistic, but they are certainly very important. I have estimated the production of this province as 500,000 tons, but this is problematical, as the area is so little known. The same remarks apply to Kansu, which adjoins Shensi on the west. I have, for this reason, omitted Mongolia from Table I, though it is known to possess coal seams in those portions which adjoin Chili and

Shansi. Passing directly south, to Ssu-chuan, Kwei-chou and Yunnan, our knowledge is in a similarly unsatisfactory state. Richthofen, who only traversed the northeastern part of Ssu-chuan, says, in substance, that coal is very generally worked throughout the province, as the Mesozoic strata are extensively folded and are cut across by the rivers, thus conveniently exposing the seams. So far as I can learn, the coal here is not of as good quality as other deposits more favorably situated with respect to the larger markets, which, together with the difficulties of transportation on the Yangtze, restricts production to the amount required for local needs.

The anthracite field of Shansi extends southward into Honan province and at Ching-hua-hsein, the Peking Syndicate is operating several shafts, equipped with modern machinery. This company has had many vicissitudes, but is now meeting with success; the production during 1910 is given as 357,205 tons. There is a good deal of production by native methods in this province.

The great southern coal field lies to the east of the Hsiang River, in Hunan and Kiangsi provinces. The greater part of the field is in the former province, but the most important producer, the collieries of the Han-Yeh-P'ing Iron & Coal Co., are at P'ing-hsiang, in Kiangsi. A view of the P'ing-hsiang colliery, showing two banks of coke ovens and the washing plant, is given in Fig. 3, and a nearer view of one bank of ovens is shown in Fig. 1. The steel headframe of the shaft is shown in Fig. 2. This coal is a bituminous coking variety (with associated thin seams of anthracite), which contains 28 per cent. of ash as mined, but after washing and drying, an average analysis, furnished by the company, gave:

Analysis P'ing-Hsiang Coal

	Per Cent.
Volatile hydrocarbons	22.35
Fixed carbon	68.90
Ash	8.70
Sulphur	0.10

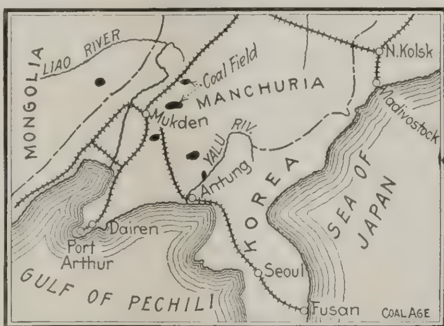

Fig. 7. Manchurian Coal Fields

It yields excellent coke, which supplies the blast furnaces at Han-Yang and the general market; more than 107,000 tons having been produced in 1909. The production for 1910 is given as 610,000 tons. The coal fields extend west and south from this point for a great distance, and Richthofen says that southward the coal is anthracite and of better quality. Transportation is difficult, owing to the shallowness of the rivers; so development has lagged; but when the Canton-Hankow Ry., now under construction, is in operation, this field, which I regard as only second in importance to the Shansi field, is likely to develop greatly. Some of the most important mineral regions in China lie to the west of the projected railway line, and the transportation facilities thus afforded should lead to a great increase in mineral production.

Conclusions

In conclusion, it should be said that the coal fields of China are of great extent, the coal is generally of good quality and the fields are widely scattered, so that no parts of the empire are far distant from the sources of supply. In extent and quality the coal resources of the empire compare favorably with those of the United States. As a rough comparison, it may be said that Chinese coals are slightly younger than those of North America, most of the fields being upper Carboniferous or Permian. In the north, Jurassic and Tertiary coals occur, but except for the Fushun field, are of little importance as yet. Bituminous coking coal is very common; coke made by native methods can be obtained almost anywhere in the empire. When made from washed coal, the resulting coke is of excellent quality, and will afford an abundant supply for the smelting industries which are likely to develop. The anthracite is of excellent quality, but the bituminous is often friable, yielding an excessive proportion of fine coal. When worked on a large scale, this can be washed and converted into coke. The Chinese custom is to make the dust into briquettes with clay as a binder. These are dried before burning. Recently the number of mines equipped with modern machinery has become comparatively great, and the present supply amply meets the demands.

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

In no other industry is there such a lack of unison was in coal mining. For this reason, men like Samuel A. Taylor, of Pittsburg, who are possessed of the ability to draw factions, as well as individuals, together, are assets of no small value.

Mr. Taylor long ago proved himself the champion banisher of discord. One cheering look from him is sufficient to cause the blackest, most threatening clouds to scurry away and leave the sky as clear and serene as a placid lake on a summer afternoon. His supply of oil for disturbed waters comes from an everlasting fountain of inexhaustible flow, and the most tumultous seas are rendered calm as death when subjected to his tender efficient care.

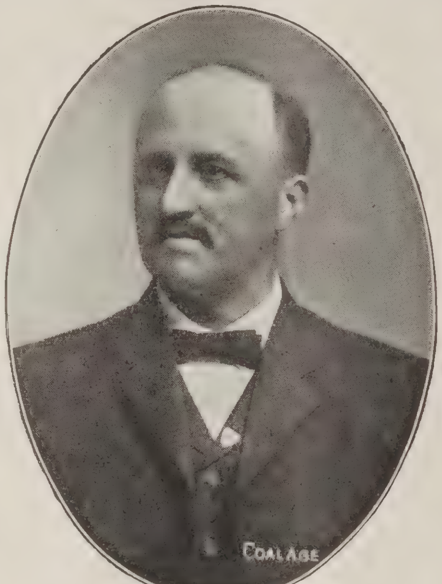
Concentration calls, not for talented men, nor yet for geniuses, but for men who are trained to do one thing as well as it can be done. In this matter of "singleness of purpose," Mr. Taylor is unusually proficient, for he has never once moved his residence from Allegheny County since he was born in North Versailles Township, Oct. 24, 1863.

He is an excellent example of the class of "Stay-at-Homes," whose mental philosophy includes a belief in the story of the "rolling stone." Samuel takes no chances on knocking off any moss, although he has confined the growth of that much desired substance to those parts of his being, not directly connected with human ideas and modern notions.

Mr. Taylor was educated at the common schools until 10 years old. At this early age he began working in the coal mines, which line of effort he followed until he was 15, when he gave up the mines and learned the carpenter trade.

At 18, he entered the Polytechnic Institute of Allegheny, Penn., and at 20 commenced his college course in civil engineering at the Western University of Pennsylvania, now the University of Pittsburg. "S. A." graduated from this latter institution in the class of 1887, and immediately got a job in the structural-iron department of the Homestead Mills of the Carnegie Steel Co., under Julian Kennedy.

He left the Carnegie people in 1888, and accepted a position in the construction department of the Pennsylvania R.R. While with this latter concern he had charge of the construction of a number of branch railroad lines until 1893, when he opened a general engineering office in Pittsburg, which was conducted by him until the close of 1904, when this private engineering practice was turned over to three of the men who had been associated with him.



Samuel A. Taylor

Since 1904, "S. A." has acted as a consulting engineer, and has managed a number of coal and water-works plants. He organized and became president of the Domestic Coal Co., the Crescent Coal Co. and later the Mifflin Coal Co. and the Corona Coal & Coke Company.

He has served on a number of mining commissions and as director of several banks, water companies and coal companies. Is a member of the Engineers' Society of Western Pennsylvania, and during the last year was president of the Coal Mining Institute of America. At the recent meeting of the American Mining Congress, in Chicago, Mr. Taylor was elected president of that body, and is today actively engaged in bringing the influence of the Congress to bear on the subject of necessary legislation looking to a betterment of conditions in the coal and metal industries.

And without I miss my guess, "Samuel A." will get some results if playing politics is all that is essential to the accomplishment. He is neither a novice nor bungler at the game, and can come nearer the consummation of a fixed plan, through affability of manner and earnestness of purpose, than paid professionals can ever hope to get by sharp trading and the bestowal of party patronage. There are many schools calculated to turn out capable politicians, but when a man has overcome the obstacles that confront a practicing engineer, and in addition has a bowing acquaintance with the inner circle of Pittsburg politics, then he is eligible to an honored place in the national hall of political fame.

Samuel Taylor is also a member of the American Society of Mining Engineers, the American Society of Civil Engineers, and a string of scientific organizations, the enumeration of which would make the "etc's" affixed to King George's name appear like a lonesome college degree compared with an open discussion on "how to fight a mine fire." In fact, no technical society today is bold enough to organize without having Samuel on its charter-member list. Might as well dispense with by-laws, officers and rules as try to get along without him.

The Association of Pittsburg Coal Operators long ago recognized Sam's cementing qualities and made him their secretary. Some day bituminous operators generally will want a Moses to lead them from the wilderness and it is a sure bet their searching gaze will light on "S. A.'s" assuring smile.

Pittsburg has long deserved recognition as a seat of mining education, and this cherished ambition may now be realized, due to Mr. Taylor's election, on Apr. 1, to the deanship of the mining school of the University of Pittsburg. For some years he has been trustee of his old Alma Mater, and when the popular and able Prof. Wadsworth resigned recently, the university officers chose "Sam'l A." to fill the place.

Ask Mr. Taylor to prepare a paper for presentation before a technical society or any meeting of serious-minded men, and if you are not particular to specify the subject, you can stake your faith and rest easy in the belief that Samuel will discuss workmen's compensation and the principle of old-age pensions for coal-mine employees. One such paper, prepared and read by him, a few years ago, has been used as a guide to a recent report of the American Mining Congress, whose suggested enactment has become the basis of proposed legislation in several states.

But it must not be inferred that S. A. Taylor plays a harp with a single string. He has marked convictions on the subject of conservation and believes that the sale of coal by analysis is the prospective cause of more willful waste of available fuel than the careless mining of earlier days.

COAL AGE

National Control of Mines

Our correspondent in his interesting article on the "Expropriation of Mines" reviews the recent British strike, and suggests that the coal mines of England and Scotland, before long will be purchased by the government of the United Kingdom. The Socialists in the Mine Workers' Union have an expectation that the same course of action will be followed in America. It is, therefore, an appropriate subject for consideration.

The demand for such nationalization seems to come not so much from the Socialists as from such patriotic people as have for many years been depreciatively dubbed "jingoes." These people appear to believe that by nationalizing the mines, the government will have a firmer hold on the mine worker and will be able to compel him to work when he is prone to seek the redress of what, rightly or improperly, he considers his wrongs.

We cannot be sure that strikes will not occur despite such an arrangement. In fact there have been several strikes threatened and not a few consummated where public utilities were in control of the national government. There are growing signs of a disaffection of postal employees and it appears that segregation has much to do with the fact that their discontent has not burst actively into flame. In Italy and France, strike suspensions have occurred on state railroads, and it is a foregone conclusion that any well organized industry which has once been afflicted with strike disturbances is likely to continue to be a fertile field for them even after the government has taken direct charge. Moreover it seems possible that strikes which paralyze a whole people could be prevented without such expropriation.

To pass laws forbidding the suspension of work by the employees of the state is a measure just as subversive of the rights of the individuals of the proletariat as to pass or enforce laws against unreasonable collectivity when bargaining for wages with private employers. In fact we believe that the control by the government of the worker in a nationalized industry would be nil.

The advocates of the new order have confused the horse with the rider. The miner would run the state, rather than the state govern the miner. This power of the operative to rule is undoubted. In fact, any organized body working in the production of a staple product and comprising over 5 per cent. of the population has that power—the farmer of America for instance. So far however, patriotism, segregation and self protection have prevented the workers in any industry from using their destructive power to involve themselves and others in a common overwhelming misfortune.

Surprised to find the Ultra-Conservatives for once in accord with them, the Socialists add to their argument the further consideration that the government with nationalized mines will pay the men a sufficient wage. The fitting wage is a difficult matter to determine, and the state might well differ with the miner as to what constitutes such a remuneration. Judging by recent declarations, we suppose that the approved miners' wage should be not less than 25 per cent. above existing labor prices. This statement cannot well be discussed with any hope of a gratifying solution. Let it be conceded, however, that the government would give such an increase. It would then be a notice to all workers that wages in general needed a similar advance. The usual readjustment would follow, and the miner would be in no manner benefitted.

The only argument which seems to have any validity is one which few are now advancing, though it has had in the past no little attention. Wages could not be readily raised in purchasing power, but it is possible that if the mines were acquired by the government, profits could, in some cases, be reduced. The government could operate the mines on a small margin not to exceed the interest charge consequent on the scale of bonds to affect their purchase. This rate of in-

terest would be three or four per cent. The average owner is perhaps making twice and certainly no more than three times that figure.

The coal operator of the British Isles is not among the more wealthy capitalists of Great Britain. In fact, it may be pointed out that it is not he who is the recipient of excessive profits. The land holders of city properties occupy this enviable position. In fact, if capital needs the curb of expropriation for the benefit of the poor, the coal operator should certainly not be the first to taste of such a socialistic experiment, because it seems probable that the public in that event would not be markedly benefitted.

In fact it is likely that the little difference between the profit, which the government might demand, and the average profit in British mines today would be more than covered by the inefficiency of the bureaucracy. If any improvement could be looked for, it must be expected to arise from the closing down of some few collieries where conditions are peculiarly unfavorable to successful operation and liberal wages. This, however, would involve a colonizing of such parts of England and Wales, as are most suited for coal production and a decrease in the output of Scotland, the Forest of Dean and Somersetshire, where coal mining is conducted under difficulties. It is likely that such an enforced exodus would be unwelcome to those colliers who live in these parts, and would not be agreeable to the industries and trades, which find in the purchases of the miners, their means of support.

Sober second thought it seems will nationalize lands, railroads, breweries and distilleries long before the mines and quarries of the United Kingdom.

The End of Coal Mining?

Press reports from England state that Sir William Ramsay has announced the perfecting of a system for extracting power from the coal in its native bed. It is only from such a man as Sir William Ramsay that such a statement would be taken seriously. Should his system prove feasible, the changes in conditions of employment and the economies it will be possible to effect are almost beyond comprehension.

According to the most reliable information now available, Sir William Ramsay proposes to tap the coal seams by means of drill holes, and by igniting the coal, drive off the gases, which will be utilized in gas engines for generating electricity.

While no intelligent criticism of the scheme can be attempted until the full plans have been made public, we can nevertheless see many obstacles to its consummation. Among these would be the provision of an adequate air supply to insure proper combustion, the difficulty of maintaining same, due to the accumulations of coke and the subsidence of the roof, and finally the necessity for an elaborate plant for treating the gases, which would naturally carry high percentages of impurities and would require careful washing before they could be used in the gas engine. Sir William would also face a further difficulty here in the shape of a patent taken out in 1909 by A. A. Betts of New York, which reads in part: "Power gas is generated from unmined coal by starting a fire at the base of one or more shafts or drill holes, supplying the air and steam through a pipe, and withdrawing the gas through the same or other shafts or drill holes."

On the other hand, there is no question but what the proposed change offers food for serious thought. The enormous hydro-electric installations of the West have fully demonstrated the feasibility of long high-power electrical transmission, while the losses involved in mining, handling and re-handling the coal from the working face to the consuming power plant are very great.

Mechanical Handling of Coal

Great progress has been made of late in our methods of handling and preparing coal. At best, its transfer from the working face of the mines to the bin of the consumer involves a more or less frequent lifting up and dropping down of this fragile material, but recently numerous devices have been sought and achieved which not only increase the efficiency of colliery operation, but tend to prevent undue breakage and degradation of the product. Conveyors have been devised which largely eliminate the prevalent five- or ten-foot fall from loading pockets to car bottom, and the long toboggan-like gravity chute has been condemned and generally abandoned in favor of spirals and similar retarding constructions.

It may be questioned, however, if these efforts have not been somewhat disconnected and sporadic in character and directed toward the correction of evident faults in existing methods, rather than dedicated to the application of a recognized principle, or set of principles, which if consistently adhered to, might be expected to produce more certain and comprehensive results.

For example, there is much evidence to support the contention that in handling coal, dependence on the force of gravity should be avoided as far as practicable, instead of embraced wherever possible as heretofore has been common practice. The mine car which is handled to or from the cage or dump by means of a descending grade may or may not move as required, depending entirely on the condition of its running gear. The railroad car which in summer has to be guarded zealously against running away, in winter may have to be coaxed along with a pinch bar.

More evident still are the limitations of gravity in connection with the distribution of material in our anthracite breakers. The character of the coal varies not only from time to time as different seams are brought within the scope of operation, but varies continually during the course of a single day, where the colliery draws its supply from several sources. The fixed gravity chute offers inadequate means for regulating the flow under these conditions, with the result that provision is usually made for the slowest material, and the balance is allowed to batter itself to pieces in precipitate flight.

It would seem that much might be accomplished toward eliminating these and many similar defects by an extended application of methods for handling the material mechanically. This is unquestionably the tendency of modern practice. We would suggest that it be recognized and reduced to a working principle. Power-operated cagers and car-handling systems, face and distributing conveyors, loading booms and many similar devices should mean positive, continuous, reliable and easily regulated progress of the coal through the course of the various colliery operations. They also should mean decrease in breakage of the product. It seems reasonable to believe that the increased efficiency and improved output which might be attained in this way would greatly over-balance the higher cost of installation.

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Coal Dust in Mine Explosions

I have only now had the opportunity of reading the editorial remarks in COAL AGE, Mar. 2, on "Afterdamp" and "Coal Dust Heterodoxies." Having just returned from attending the inquest and investigating the Merritt disaster, I beg to offer a few remarks, which I hope will provoke further discussion that will help to elucidate the questions we are studying.

First, with regard to afterdamp, I take this term, as used in mining, to mean any mixture of gases resulting from the explosion or violent inflammation of gas or dust, in a coal mine. Some years ago I was myself puzzled by the effect of afterdamp on the eyes. I attributed this effect to ammonia, but a student and lecturer on mine gases (Dr. Carnelly, now dead) assured me that this was not probable and made tests to prove it. If I remember correctly, he suggested that the effect was due to an oxide of nitrogen that might be produced in a mine explosion. Whatever is said in regard to the composition of afterdamp one thing is certain, that the afterdamp resulting from an explosion in a mine has never the same composition. The kind and quantity of gases formed will depend wholly on the conditions attending the explosion.

COAL DUST HETERODOXIES

Your remarks under this head appear to be principally based on the extract you quote from my paper entitled "Some Coal Dust Explosion Problems." This paper, which was prepared and presented to the South Wales Institute of Engineers, is now under discussion by the institute. I regret that the whole of the paper was not before you when making the comments you did, as this would have enabled you to have prepared a better synopsis. For example, you make no reference to my quotation from the French experiments at Lievin and you omit to mention or describe what forms the most instructive part of the paper; namely, the photographs showing the damage done to the testing tubes or galleries and the general effect of the explosion.

Your editorial leads one to infer that I have been writing on the detonation of coal dust; whereas, the cases I quote are suggestive only of the detonation of gases created at a certain stage in a coal-dust explosion. This is not a detonation of the dust particles, each floating in its own balloon of gas.

WATERING IN COAL MINES

The last paragraph in the editorial to which I have referred gives a clear opinion on the subject of watering or dampening of mine air that is directly contrary to my own expressed opinion and writings on this subject. I am not speaking now of watering down or spraying accumulations of dust at the working face or on roadways; but refer to the humidification of the mine air by spraying. It will be remembered that Prof. Harold Dixon, some years ago, published his conclusions in regard to the effect of coal dust in mine explosions, in a paper entitled "The Rate of Explosions in Gases." In this paper, Professor Dixon distinctly states that mixtures of certain gases with air give the highest speed in explosion when the mixture contains 5 per cent. of water vapor. The point I wish to emphasize is that *it is this high speed produced when water vapor is present that gives the detonating effect of the gas* to which I have referred. If some high authority on explosive gases can explain away Professor Dixon's conclusions in this regard, I may be inclined to think that the humidification of the mine air is of some value. Up to the present time this has not been done and we must believe that the presence of water vapor in mine air is a factor that will increase the speed and violence of an explosion. To put this a little more strongly, I would say, that the presence of the water vapor tends to cause a detonating effect, which is the point intended to be brought out in my paper. I am glad to note that in closing you express a lingering doubt as to the ability of humidification to immunize the mine as we might wish it could.

[We are glad to give space to these comments of Mr. Ashworth and regret that the entire copy of his paper is not available at the present time. Mr. Ashworth has certainly made some valuable deductions that cannot fail to make interesting subjects of discussion. It is only just to Mr. Ashworth, whose views in regard to mine explosions command respect, to state here that he has always advocated the thorough wetting down of the coal face and immediate vicinity before firing blasts in dusty mines where blasting is dangerous; and the spraying of the mine roads to such extent as may be necessary to keep the air on these roads clear. See "Mine Gases and Explosions," p. 193.—EDITOR.]

The Fireboss Question

I would like to congratulate the writer of the communication signed "A Fire Boss, Western Pennsylvania," COAL AGE, March 9, p. 717. He suggests that there should be a law passed, or that the Department of Mines should make a ruling prohibiting mine bosses and mine foremen who are regularly employed as such from acting in the capacity of fireboss at any mine generating explosive gases. This strikes me as an excellent suggestion. We firebosses have felt for a long time that we have no protection in our work, and that we are particularly subject to difficulty in attempting to carry out the state mine law and at the same time please our employers, by whom we are paid.

I would suggest that all firebosses who feel the same write to their respective representatives, at Washington, D. C., and also to the legislators of their respective districts, at the State Capitol, urging the passage of a law such as has been suggested. The law should also require that all firebosses charged with the responsibility of the daily examination of mines generating explosive gas, shall act under the jurisdiction of the State Mining Department, in their respective states. The law should make all firebosses in gaseous mines responsible solely to the district mine inspector and subject to his control, or to the Department of Mines, in each state. I think such a law could be worked out all right and would be more satisfactory, both to the miners and operators. There is no question but that such legislation would please all firebosses.

AN INDIANA FIREBOSS.

Electrical Machinery for Coal Mines

Referring to the article, "Electrical Machinery for Coal Mines," in COAL AGE of Mar. 16, and to the last paragraph but one on p. 737, I note that the author, in speaking of the speed variation of the three-phase induction motor, says that by cutting down the number of pairs of poles by one-half, the speed of the motor is reduced in the same proportion. Also, in the last paragraph, he states that, for a machine having six pairs of poles, the speed would be reduced 33⅓ per cent. by cutting out two pairs of poles.

I would differ with the author in these statements and would say that, as I figure it, reducing the number of poles of an induction motor by half would increase the speed in the inverse proportion. In other words, speed varies inversely as the number of pairs of poles, that is, of course, theoretically. Practically, the slip must be taken into consideration in making a statement of this kind.

I would be interested to hear what the author has to say in regard to this criticism and how he can explain the relation of frequency to speed and pairs of poles in such a way as to agree with the statement he has made. As I have always understood it, frequency equals pairs of poles multiplied by speed. The author seems to figure it the other way.

Syracuse, N. Y. H. V. BROWN.

[It is quite apparent that the statements referred to by Mr. Brown are in error, and should be changed to read as he has suggested.—EDITOR.]

A Graphic Solution for Pumping Problems

Note—From the "American Machinist."

When dealing with pumping questions it often entails a fair amount of "figuring" to obtain say the power required to pump a certain quantity of water to a given height, when the efficiency of the pump is known, or having a certain amount of power available how much water can be raised to a certain height per hour? To arrive at any of the above answers a considerable amount of time is involved, whereas with the following diagrams any of the above requirements can be seen at a glance.

The accompanying diagrams give the brake horsepower, number of gallons per minute, and per hour, the various heads in feet, and the pump efficiencies from 15 ft. up to 300 ft. head.

As an example, we require to pump 360 gal. per minute with a total head of 85 ft. and the efficiency of the pump is 60 per cent. What is the brake horsepower required?

On the left-hand side of the diagram is shown gallons per hour and gallons per minute. On the line 350 gal. trace along toward the right hand until the horizontal line intersects the diagonal line marked "85 feet head." Then trace the vertical line at this intersection downward and at the bottom of diagram will be read the b.hp. = 13, on the horizontal line of 60 per cent. pump efficiency where the vertical line intersects.

Letchworth, England. W. E. WORT.

Short Circuiting Air Current, Effect on Speed of Fan

Some mining men claim that when the mine fan is working up to nearly its full capacity, and the air is short-circuited, the fan will speed up and the water gage will fall. According to my ideas, if the water gage is placed so that it only measures the mine resistance, the short-circuiting of the air current at the shaft bottom and the consequent cutting off of the mine resistance, will cause a fall of water gage, and at the same time the fan will slow down somewhat, owing to the increased amount of air passing. If, however, the water gage is so placed that it measures the resistance of the fan and the mine the water gage will be increased when the air is short-circuited, while the speed of the fan will be slightly reduced, as before. This result, I believe, would be due to the resistance in the fan being somewhat increased by the increased flow of air through the fan.

I would like to have this question definitely answered, and also to see it discussed by the readers of COAL AGE.

BENJAMIN HARTILL.

Johnstown, Penn.

Our correspondent is correct in his first statement; namely, when the air current is short-circuited at the foot of the shaft, the water gage will fall and the speed of the fan be reduced, assuming the power applied to the fan shaft remains constant. There is, however, no position of the water gage possible in which it will measure both the resistance of the mine and that of the fan. The water gage reading taken at the bottom of a shaft measures the difference between the intake pressure and that of the return at that point, which difference of pressure (lb. per sq.ft.) multiplied by the sectional area of the airway where the reading is taken (sq.ft.) represents the resistance of the mine inby from the point where the water-gage reading is taken. On the other hand, when the water gage is placed on the fan drift its reading measures the difference between the atmospheric presure and the pressure in the fan drift (lb. per sq.ft.), which multiplied by the sectional area of the fan drift (sq.ft.) represents the total resistance met by the air current in its passage from the fan to the point where it is discharged into the atmosphere.

There is no way of measuring the resistance of the fan to the passage of the air. This can only be estimated, and determines what is called the efficiency of the fan. It will not be necessary to consider the matter of the efficiency of the fan when the air is short-circuited or the mine resistance cut off, further than to say the quantity of work lost or absorbed in the fan itself varies practically with the cube of the quantity of air passing through the fan.

Assuming 100 horsepower is applied to the fan shaft, as indicated by an indicator card taken from the engine driving the fan; perhaps, of this amount, 80 horsepower is consumed in circulating the air through the mine and the shafts, leaving 20 horsepower absorbed or lost in the fan. Assume that 80,000 cu.ft. of air are in circulation before the air is short-circuited; and after short-circuiting the air by setting open the main separation doors at the foot of the shaft, say 100,000 cu.ft. of air are passing through the shafts. The quantity of air passing through the fan is thus increased in the ratio

$$\frac{10}{8} = \frac{5}{4} = 1.25$$

and the power absorbed or lost in the fan, increasing as the cube of this ratio, is 1.25^3 = say 2 times or double the previous loss of power. That is to say, after short-circuiting the air, 40 horsepower is lost in the fan and the remaining 60 horsepower is therefore consumed in passing the air through the shafts. These results are tabulated below.

Before change:		
Fan	20 hp.	80,000 cu.ft.
Mine and shafts	80 hp.	
After change:		
Fan	40 hp.	100,000 cu.ft.
Shafts	60 hp.	

From the above it is clearly seen that owing to the increased loss of power in the fan the effective power available for moving the air is decreased from 80 horsepower before the air was short-circuited to 60 horsepower after the change was made. It is this effective work that is concerned in turning the fan, and the speed of the fan varies as the cube root of the horsepower; or, in this case,

$$\sqrt[3]{\frac{60}{80}} = \sqrt[3]{0.75} = 0.9$$

That is to say, the speed of the fan after short-circuiting the air will be about 0.9 of what it was before the air was short-circuited. If the first speed was, say 100 r.p.m., the second speed will be about 90 r.p.m. In common mining practice the speed of the fan in short-circuiting the air drops about 5 or 10 per cent., according to conditions.

Direction in which a Mine Explosion Propagates

Does an explosion of gas or dust in a mine always develop its greatest magnitude in the direction from which fresh air comes, or against the air current?

TOM. E. FITZGERALD.

California, Penn.

In considering the explosion of gas or dust, the mine or that portion of it where the explosion occurred must be considered, in most cases, as a *cul de sac*, or confined space in which the gases produced by the explosion expand toward the opening as though shot from a gun.

This condition, however, describes only the initial force resulting from the ignition and explosion of an accumulated body of firedamp, or the violent inflammation of a cloud of dust, which forms the center of the disturbance, and from which the force radiates in every direction. The force cushions inby but expands freely outward or in the opposite direction.

There are two general types of explosions in mines with respect to the manner of their propagation. (1) Propagation by percussion; (2) propagation by burning. In the first of these two types of explosion the force or explosive effect is transmitted with lightning rapidly throughout the entire mine. There is much that is yet to be learned in regard to the principle of action of this form of explosion. Theories have been suggested to account for the phenomena, and these are being closely studied, at the present time. Whatever may be true in regard to the principle by which the explosive wave is transmitted, it is a fact that this type of explosion may be either with or against the air. The direction of the air current appears to have little effect in determining the direction of the blast.

In the second type of explosion, that in which the explosive wave advances more slowly, by burning the combustible material (gas and dust) lying in its path, the explosion can advance any great distance, only in the direction in which it is fed by fresh air. That is to say, the advance is in the direction against the air current. The reason for this is clear when one considers that owing to the lack of air for its support the explosion would be snuffed out in its own trail, in the opposite direction.

Examination Questions

Interesting Questions

(Answered by request)

Thickness of Mine Dam Required to Support a Given Head

Ques.—Having decided to dam off a heading 15 ft. wide and 6 ft. high, with a concrete dam, using a mixture of cement, sand and cinders, in the proportions 1:3:5; it is desired to know the total pressure against the dam and the thickness of the dam required to withstand such pressure (a) when the water stands 5 ft. above the pavement, at the dam; and (b) when the water will back up and reach a level 30 ft. above the pavement at the dam.

Ans.—The total pressure exerted by water on a dam is found by multiplying the wetted area of the face of the dam (sq.ft.) by 62.5 (wt. of 1 cu.ft. of water in lb.), and this product by the vertical height of the surface of the water above the center of gravity of the wetted area.

(a) The water being 5 ft. deep at the dam, the wetted area of the face of the dam is $5 \times 15 = 75$ sq.ft. The center of gravity of this area is its center of figure, which is 2.5 ft. below the surface of the water. The total pressure on the dam, in this case, is

$$75 \times 62.5 \times 2.5 = 11{,}718+ \text{ lb.}$$

For practical considerations it would not be advisable to build a dam of this width, with a thickness less than, say 20 in. or 2 ft., although the calculated thickness for this depth of water is much less.

(b) When the water stands 30 ft. above the pavement, the wetted face of the dam is $6 \times 15 = 90$ sq.ft. The center of gravity of this area is its center of figure, which is $30 - 3 = 27$ ft. below the surface of the water. Hence, the total pressure on the dam is now

$$90 \times 62.5 \times 27 = 151{,}875 \text{ lb.}$$

To calculate the required thickness of the dam, let

t = Thickness of dam (in.);
r = Shorter radius of dam (in.);
w = Width of opening or span (in.);
p = Pressure of water at dam (lb. per sq.in.);
S = Compressive strength of material (lb. per sq.in.)

For a cylindrical dam

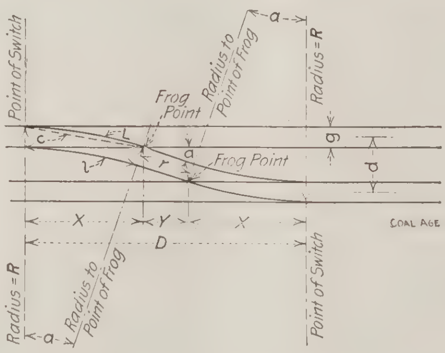
$$t = \frac{pw\sqrt{4r - 1}}{4S}$$

The shorter radius of the dam should be from ¼ to ⅓ greater than the clear span or width of opening. In this case, r = say 20 ft. (240 in.); $w = 12 \times 15 = 180$ in.; $p = 27 \times 0.434 = 11.718$ lb. per sq.in.; and $S = 600$ lb. per sq.in. Hence, the required thickness of a cylindrical concrete dam to support the given head of water is

$$t = \frac{11.718 \times 180\sqrt{4 \times 240 - 1}}{4 \times 600}$$
$$= 27+, \textit{ say } 30 \textit{ in.}$$

Calculating A Crossover Switch

Ques.—(a) Explain the method and give the necessary formulas for calculating the lengths and distances required to lay a good crossover switch between two parallel tracks in a mine. (b) Find the several dimensions of a crossover switch for a 30-in. track gage when the distance between track centers is 7 ft. and a No. 3 frog is used in each track.



Calculating A Crossover Switch

Ans.—(a) In considering a crossover switch there is usually,

Given,
- frog number (n)
- track gage (g)
- track centers (d)

To find,

chord of lead rail $c = 2ng$

radius of lead rail $R = nc$

frog angle $\sin. \tfrac{1}{2} a = \frac{1}{2n}$

length of lead rail $L = \frac{a}{180}\pi R$

length of follower $l = \frac{R - g}{R} L$

length of straight track

$$r = \frac{d - g(1 + \cos. a)}{\sin. a}$$

lead of switch $x = R \sin. a$

frog distance apart

$$y = r \cos. a - g \sin. a$$

distance between switches

$$D = 2x + y$$

The letters in the formulas refer to the dimensions specified in the accompanying figure.

(b) When $n = 3$, $g = 30$ in. (2.5 ft.); and $d = 7$ ft.

chord of lead rail

$$c = 2 \times 3 \times 2.5 = 15 \textit{ ft.}$$

radius of lead rail

$$R = 3 \times 15 = 45 \textit{ ft.}$$

frog angle

$$\sin. \tfrac{1}{2} a = \frac{1}{2 \times 3} = 0.1666;$$
$$a = 19^\circ 12' = 19.2^\circ$$
$$(\sin. a = 0.3289;\ \cos. a = 0.9444)$$

length of lead rail

$$L = \frac{19.2}{180}(3.1416 \times 45) = 15.08 \textit{ ft.}$$

$$l = \frac{45 - 2.5}{45} \times 15.08 = 14.24 \textit{ ft}$$

length of straight track

$$r = \frac{7 - 2.5\,(1.9444)}{0.3289} = 6.50 \textit{ ft.}$$

lead of switch

$$x = 45 \times 0.3289 = 14.8 \textit{ ft.}$$

frog distance apart

$$y = 6.5 \times 0.9444 - 2.5 \times 0.3289 = 5.31 \textit{ ft}$$

total length of crossover

$$D = 2 \times 14.8 + 5.31 = 34.91 \textit{ ft.}$$

Percentage of Gas in Return

Ques.—If, after making due allowance for the expansion of the return air current caused by a rise of temperature and a fall of pressure, the air measurements taken on the intake and return airways still show an increase of 2500 cu.ft. on the return; (a) how is this increase in volume to be explained? (b) what percentage of gas is then contained in the return current when there is 120,000 cu.ft. of air and gas passing.

Ans.—(a) The increase in the volume of the air current is probably due to the mine gases absorbed by the current in its passage through the mine. These gases may and often do consist largely of marsh gas generated in the mine.

(b) The percentage of gas in the return, in this case, is

$$\frac{2500 \times 100}{120{,}000} = 2.08\%$$

For the Betterment of Living Conditions in Mining Communities

Housing of Scottish Miners

It has always seemed that those who would prepare for the housing of foreign miners, should know something about the character of the structures to which those miners have been accustomed. The illustrations accompanying this article are taken from the report of J. C. M'Vail, officer of health for Sterling and Dumbarton Counties, which shires are in the narrow waistline of Scotland, between the Firths of Forth and Clyde. The facts herein recorded have the same source.

Two-room Houses Predominate

It will be noted that all the houses are substantial, being made of brick or stone and roofed with slate, but on some of the older houses red-tile roofs are to be found. The apartments are usually built in long blocks, but greater privacy is secured in these than in the average American miner's double house, because the walls are invariably made of brick. But it will be noted how rarely does one tenant uses more than two rooms. One of these serves as a kitchen and the other as a combination of bedroom and parlor. The latter chamber is termed impressively *"the room."*

Of 873 miners' houses in the two counties, 2.5 per cent. have one apartment, 84.2 per cent. have two, 11.5 per cent., three, and only 1.8 per cent. have as many as four rooms. It is probable that in the United States as large a proportion of four- and five-roomed miners' houses are to be found as of two-roomed houses in the Lowlands of Scotland.

Cheerful Appearance

A long walk, sometimes of concrete, is laid close up to the house fronts and between this and the wagon road is placed a surface channel for drainage. At the back are small outhouses and beyond them small gardens or clothes-drying greens. Sometimes an attempt is made to arrange a cheerful color scheme by making the quoins and arches of the windows and doors with contrasting material. In like manner, the outlines of the blocks and the edges of the chimneys are brought out plainly. This feature is one worthy of comment, because it does not involve any expense and certainly serves to correct the barrack-like appearance of house-blocks.

Damp-proofing

One feature of the Scotch houses is the attempt made to exclude moisture. If the walls are of stone, they are furred and lathed before plastering, but if they are of brick they are built hollow with an air space of three inches, and the plastering is then placed on the brick. One plan is followed about as frequently as the other. Mr. McVail, however, declares the first one to be the most efficient as a defense against moisture. It is urged that the arrangement of furring and lathing is not as strong as the other, and not suited to houses likely to be occupied by boisterous tenants.

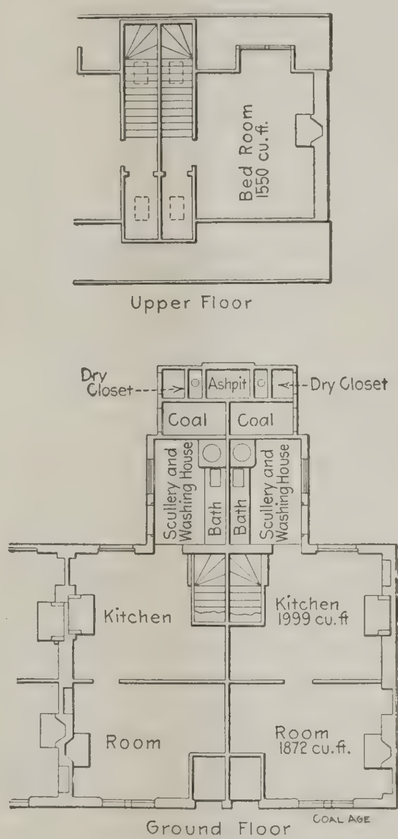

Fig. 1. Present-day Type of Homes of Scotch Colliers

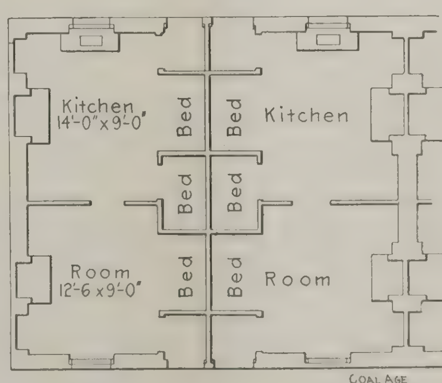

Fig. 2. Plan of Older Types of Miners' House, Scotland

Wherever a wall is made thin to accommodate a clothes press, it is necessary to make it waterproof by lathing and plastering, and at the sides of doors and windows, if the outer and inner divisions of a hollow wall are connected by brickwork, dampness is apt to be admitted from rain beating on the wall. At doors and windows either the hollow must be carried up to the woodwork, or else the brick must be dipped in tar or some other damp-proof compound.

Damp-proof courses are always required, and in obtaining a permit for the erection of a house under the Public Health Act of Scotland, the material and thickness of this course must always be specified. Caithness paving stone is considered desirable for that purpose, but other material is also used. The frequent use of a porous clamp-burned brick made open in texture by admixture of slack coal in the clay before burning and the natural dampness of the British Isles combine to make these precautions necessary.

Modern Conveniences

All the houses have some species of drainage provision. When fecal matters are not discharged into the sewers, open invert drains are frequently used. These are often made of concrete. These open drains are placed between the walk and the road, and connect eventually with the underground system. Some of them are flushed several times daily by automatic flush tanks.

In 14.5 per cent. of the houses, the sculleries have a clothes boiler, and in 85.5 per cent. there are outside wash-houses. Baths have been provided in 7.9 per cent. of the houses. In 67.5 per cent. an indoor water supply is provided. In 30.2 per cent. of the cases the tenants draw and carry the water from outside pillar wells. In 38.2 per cent. of the houses, water closets are provided, while in 61.8 per cent. of the houses dry closets are in use. In many cases one closet serves for two houses. Dust bins are usually provided for dry refuse, but ash pits are more common. These are roofed to keep out the rain and sun.

The Bed Place

Many of the houses have the antiquated Scottish bed places—recesses built in the walls to hold a bed. Fig. 2

shows such an arrangement. Two bed places are in the kitchen and one in the "room." At one time these bed places were closed in, even more than today. Where such a closet, as in Fig. 2, is used for a bed, the conditions are little better than exist when a box bed is used. Even the most open of set-in bed places are adorned with curtains, which hinder access of air.

To check this fault, the wooden "brow band" at the ceiling is now forbidden. Sometimes to prevent this hanging of curtains, the brick partition between the two kitchen bed places is plastered and not lined with wood. But the provision is ineffectual and the final result is that the plaster is often broken by the driving of nails to hold curtains. Wooden bed boards and "stocks" were formerly as universal as bed places, and did not make for cleanliness, but were apt to harbor vermin if the house was not kept clean. Occasionally a defaulting tenant about to vacate a house, would combine economy with sanitary reform by using the bed boards for firewood, a theft of lumber duplicated in America where yards are fenced in. In planning the houses of some of the newer villages, the owners have acceded to the request to provide iron bedsteads for the bed places. Also, in the "room" there is often now no set-in bed place, but only an iron bedstead in a corner, as in bedrooms of better-class dwellings.

Sculleries

As has been seen, the house of two apartments is the standard accommodation for a miner and his family. This is quite a usual size of house for the working classes in general throughout Scotland, but in many modern two-roomed houses a good scullery is provided, which is an important addition to the amenity of the dwelling. Of the 873 houses for which plans have been passed under the building by-laws, 422 are provided with sculleries. These sculleries, if they have a water supply, facilitate the keeping of the kitchen tidy and comfortable as a sitting room and living room.

Light and Ventilation

The minimum window area required is one-tenth of the floor space, and under the by-laws, windows are invariably sashed and double hung, so that one-half of the total space is available for ventilation. Care is taken that the window tops reach as near as possible to the ceiling to facilitate ventilation. In rooms where there is no fireplace and chimney, special means of ventilation are required, and this consists almost invariably in a roof ventilator—a circular tube at least six inches in diameter, protected by a cowl. In the kitchen, where there is always a fire, the chimney is, of course, an important aid to ventilation.

In the great majority of two-roomed houses, there is only one entrance—the kitchen door—"the room" being usually directly off the kitchen, so that through ventilation is obtained by means of the kitchen window behind, through the intervening doorway.

The floors of the houses are usually of wood, but sometimes the kitchen floor is paved with brick or concrete. The wood floors are usually ventilated underneath, but not in all the older houses.

Conclusions

On the whole it may be said that the average miner's house in Scotland is more substantial, and better equipped than in the United States. It supplies, however, quarters too narrow to suit the average American workingman, and it lacks in adequate ventilation. The curtilage accompanying each apartment is severely restricted, for which there is little occasion here, where land is plentiful.

Closing one's eyes resolutely to unfavorable features, one can see a number of points which might well be adopted with advantage. It is certain that the average five-roomed American cottage, too often contains a room devoted solely to an occasional gratification of the family pride. The chromos on the walls and the crayon enlargements on easels in such rooms infrequently gaze on the few honored guests who are privileged to enter, but for the most part rest in undisturbed darkness and stuffiness. It is, perhaps, a folly to plead for a more sensible return to the simple life, because arbitrary demands of society are usually more inexorable than its needs. Granted, however, that five rooms are unneeded, it is a far cry from that to the cabined simplicity of life in a two-roomed house, no matter what comforts may be offered as a palliation.

The Scotch house has arisen from Scotch conditions, just as the American miner's dwelling has developed from the settler's or the farmer's house. Wood has been cheap in the United States. A large house was, therefore, possible, and is now considered essential. But, as the mines have been started in places remote from cities, all the discomforts of rural life are to be found in miners' dwellings—lack of sanitary conveniences, water obtained from outside wells, pipes and springs, cheap construction, the lack of places for the disposal of garbage and the absence of bathrooms. In time, evolution will give us fewer rooms, as the inevitable result of the greater cost of materials. But the miners will have more conveniences as the certain outcome of greater crowding, which permits such betterments, at the same time as it makes them absolutely necessary.

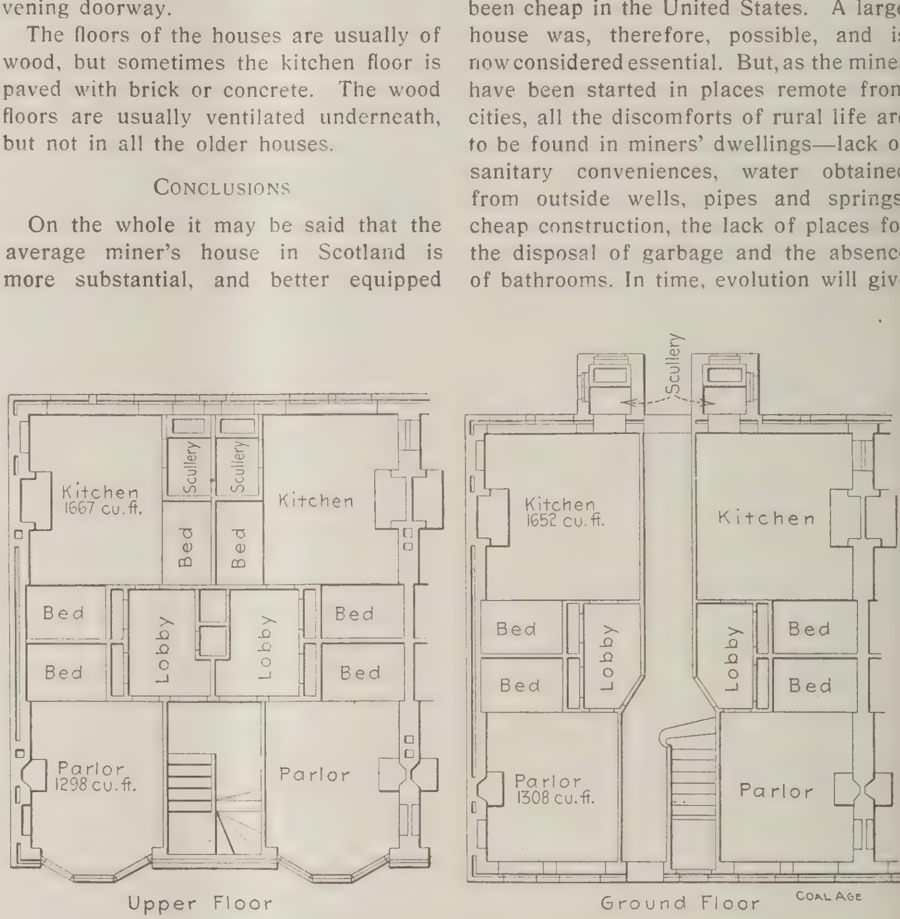

Fig. 3. Part of a Two-story Block of Houses, Designed for Scotch Miners

A Tree For Mine Camps

Few trees are better suited for resisting depressant fumes than the sycamore. It has a world wide growth and thrives wherever planted. The sycamore is quite generally found south of the 41st parallel. More northerly the climate seems too rigorous for its growth and even just south of that line, it is not much seen where the elevation is considerable. It has the great advantage of a yearly shedding of its outer bark, and thus where exposed to smoke and noxious fumes it shows itself resistant to these influences and quite hardy. It is found growing in cities like London, England, where the products of the combustion of large quantities of bituminous coal are fatal to most trees.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

Judge Martin A. Knapp, of the Commerce Court, appeared on Apr. 15 before the House Committee on Interstate and Foreign Commerce, to explain the terms of the bill drawn up by a subcommittee in conference with himself and Dr. C. P. Neill, commissioners of labor, to extend the terms of the Erdman act to the arbitration of strikes in the coal industry. Judge Knapp explained that the Lee bill, which was originally referred to the committee, has been changed in many particulars.

For one thing, it has been extended to include all classes of railroad employees. The present measure can be applied to not more than one-third of the railroad men. In connection with extending the act to the coal industry, Judge Knapp said that he preferred not to discuss the constitutionality of this provision, in view of his position in the judiciary. However, he explained that since the act is not compulsory, but the invocation of it entirely voluntary on the part of the contending parties, it appears to him that the courts would never be called upon to exercise any power in that connection, and the question of constitutionality would never be brought up.

Application to Other Industries

He was then asked, if the constitutionality of the law will never be questioned, why it should not be extended to all industrial operations, intrastate as well as interstate. The witness said that he believed that the terms of the act should be gradually extended, but that it should be done slowly and the way carefully felt. In the first place, it should be made to embrace those industries which are of the most importance to the welfare of the country. For this reason it was thought well to extend it to the coal industry first. He was then asked if it would be constitutional for Congress to appropriate money to arbitrate industrial disputes which are clearly intrastate. To this Judge Knapp said that it had been noted in the bill that the law could not be invoked except in those cases where the coal went into interstate commerce.

The third important change suggested in the bill was the provision for substituting for the present mediators, a regular board of mediation and conciliation. Judge Knapp said that he and Dr. Neill had no complaint to make, but that the duties of administering the Erdman act, in addition to their regular work, have become extremely heavy, and that inasmuch as it is proposed to extend the terms of the act to other industries, the services of at least one man would be needed all the time. For this reason the bill provides for the creation of the office of Commissioner of Mediation and Arbitration, with a salary of $7500.

Pittsburg District Extended

In a report in the case of Clyde Coal Co. vs. the Pennsylvania R.R. Co. *et al.* the Interstate Commerce Commission has handed down a verdict in which the present rate on coal from Clyde siding, Fredericktown, Penn., to Ashtabula Harbor, Ohio, when for transshipment by vessel on the Great Lakes to points beyond, is found to be unreasonable to the extent that it exceeds 78c. per net ton, which is the rate ordered by the Commission to be established from the Pittsburg district to Ashtabula Harbor. The southern boundary of the Pittsburg district is changed to include complainant's mine.

The opinion of the Commission goes on to say:

There is no evidence that traffic from the Clyde mine to the lake would move through any part of the Connellsville district. A wide area of undeveloped coal lands, probably 60 miles across, separates the Clyde property from the Fairmont district proper, and there is no railroad connecting the two localities. From the facts before us in this proceeding the conclusion is inevitable that the Clyde mine cannot be consistently included within the Fairmont-Connellsville rate group.

In forming the Pittsburg district, the carriers have followed no hard and fast rule; they have taken in mines more distant from Pittsburg than the Clyde, and the contour of the district has been materially changed so as to include certain mines and exclude others. All grouping for rate purposes is necessarily more or less arbitrary. Group lines generally have the appearance of injustice to some point just across the line. Yet the line must be drawn somewhere or the grouping abandoned. Once established, groups should not be lightly or unnecessarily disturbed.

We do not think the defendants have justified the eccentric movement of the Pittsburg district boundary line where it sidesteps complainant's shipping point. We believe that the location of the Clyde mine close to the 30-mile radius from Pittsburg, its accessibility to one of defendants' assembling points for lake-cargo coal, and other facts before noted, all combine to show that it properly belongs within the Pittsburg district and is entitled to the rate of 78c. ordered by the Commission to become effective from such district.

Alabama

Birmingham—The Roden Coal Co claims to have broken all records for coal output in the Cahaba field. At its Marvel mine, the production during March was 28,065 tons with a maximum output of 7400 tons for one week and 1435 tons for a single day. The Roden company has recently secured a year's contract for supplying coal for all vessels of the United Fruit Co., sailing from Mobile and Pensacola, amounting altogether to about 50,000 tons.

It was recently announced by the Woodward Iron Co. that all details of the merger with the Birmingham Coal & Iron Co. have been completed and the consolidation is now in effect. The new company is incorporated in Delaware. No plans for improvements, other than those for the new byproduct ovens and blast furnace, have as yet been announced. By its new acquisitions the Woodward company secures an immense acreage of coal and ore deposits and becomes practically impregnable in the raw material market.

Illinois

Chicago—Union mine workers in Illinois, as in other states of the central competitive field, voted Apr. 10 on the acceptance of the Cleveland wage-scale agreement. A statement received from officials of their organization, urged the men to accept the scale on the ground that it would restore the interstate trade agreement and permit the miners to give their entire attention to the organization of nonunion fields.

A proposed advance of 5 per cent. on the rates of soft coal over the Chicago, Burlington & Quincy from mines in Illinois to Clinton and Lyons, Ia., via Chicago, effective Apr 25, has been suspended by the Interstate Commerce Commission until Aug. 3.

Assumption—The mine of the Assumption Coal and Mining Co. was damaged recently by a caving in of the surface near the escape shaft. The loss is estimated at $3000.

Westville—The Bunsen Coal Co. is taking advantage of the suspension to have repairs made wherever they are needed at its different mines. The Bunsen mine No. 4 is receiving a general overhauling. New haulage ropes are being put in, two new cages are being built, a new hoisting drum is to be put in the engine room, two electric motors are to

be installed to haul the coal from the "latches" to the "bottom" and the shakers that have been in use for some time are to be taken out and replaced by new screens.

Danville—Three thousand miners in the coal fields of Danville and vicinity are temporarily idle awaiting the result of the vote on the proposed wage scale. The operators generally are taking advantage of the enforced idleness by cleaning out the mines, and several mines will be fitted out with new machinery during the lull in operations. The installation of new machinery and the cleaning of the mines are practically impossible while work is going on and the lay-off is not regarded entirely in the light of a hardship.

Indiana

Indianapolis—That 90 per cent. of the soft-coal miners throughout the country have approved the proposed two-year wage contract, was announced, Apr. 11, by Edwin Perry, secretary-treasurer of the United Mine Workers, after he had received telegrams from representative locals, reporting results of the referendum vote. The weekly pay question is one which is expected to operate against the agreement in this state. The new contract voted on, says nothing about a weekly pay, but contains a clause which states, in effect, that aside from the increase in pay specifically provided in the contract, there shall be no change in conditions which will add to the cost of production. Operators have insisted that the weekly pay day would add to their cost of operation, as compared with the bi-weekly pay, and some have so notified the miners. Dissatisfaction with this situation, it is believed, will be shown when the official vote in the Indiana fields becomes known, and for this reason the percentage of miners favoring the agreement is expected to be less in Indiana than in Ohio, Illinois and western Pennsylvania.

Clinton—The recent announcement that the Brazil Block Coal Co., which operates mines Nos. 6 and 8, south of Clinton, in the Vermillion County field, would go out of business, has been followed by the information that the mines have been purchased and taken over by the Oak Hill Coal & Mining Co. D. B. Medill, who came to this state after Mr. Deering and his associates and took over the Oak Hill mines, is to be the local head of the seven operations in this field.

Linton—A seam of superior grade coal has been found on leased land between Linton and Pleasantville, in the Green County field, where drilling has been going on for some time. It is understood that four new mines will be opened this year by a local company now forming. Eastern capitalists are financing the deal.

Kansas

Pittsburg—Two new steam shovels have been ordered by the Ellsworth-Klaner Construction Co. for work in stripping the property of the Central Coal & Coke Co., near Weir. It is claimed that the shovels will be the largest in the world. When they arrive, there will be 9 machines of this kind at work in the vicinity of Pittsburg. There are large areas of coal land in this region, passed by in previous mining operations, that are now being stripped.

Kentucky

Louisville—The coal operators and miners of western Kentucky have reached an agreement on a wage scale after numerous conferences. The joint conference committee finally decided to accept the scale adopted at Cleveland, and will meet again at Central City, to approve a number of details referred to a subcommittee. The men insisted, for a time, on an increase in the estimated ratio of lump to mine-run coal produced. Their demand that the operators pay the cost of shotfiring was relinquished. The new scale will give the miners an increase of 5c. a ton for lump coal, 3c. a ton for run-of-mine, and 5.26 per cent. on day wages.

The Pioneer Coal Co., of Louisville, has begun operations at its mine in the Straight Creek district near Pineville. The present output is three cars a day, but this is to be greatly increased.

Providence—The Luton Coal Co. has been making improvements to its plant, installing an air compressor and other mining equipment. It also has additional miners' houses under construction.

Ohio

Steubenville—The sheriff has been asked to appoint deputies to preserve order at the Bradley mines of the United States Coal Co. The company desires to maintain pumpers and track repairmen in the mines during the suspension, but the Italian miners, refusing to permit it, have engaged in several riots and have injured a number of pumpers and others. The men who filed information in court against their assailants were expelled and thrown bodily from the union hall.

Bellaire—Deeds of transfer filed in the Belmont County courts at St. Clairsville, Apr. 9, gave the first intimation of a big deal in eastern Ohio coal lands. The No. 8 Coal Co., stockholders and officers of which are thought to be Pittsburg and Cleveland capitalists, have bought the Belmont Coal Co.'s property, consisting of 8000 acres of coal, three operating mines and valuable surface land. The property is estimated to be worth $3,500,000. The Lorain Coal & Dock Co. had arranged to purchase the property a year ago but the final transfer was stopped because some of the land titles were not clear. Since then all titles have been cleared up.

Martins Ferry—Three thousand miners resumed work in Belmont County on Apr. 2. They are employed in the mines of the Etna-Standard and Laughlin plant of the American Sheet & Tin Plate Co. and the Whitaker & Glessner plant of this city. The resumption followed the signing of the scale by the company, on permission of the miners' policy committee. Eight thousand other miners in the county will remain out pending the result of the referendum vote.

Columbus—While no official statement has been given out, it is unofficially announced that more than 90 per cent. of the miners in the Ohio field have voted in favor of the adoption of the new wage contract drafted at the recent joint conference. The official announcement is expected to be made shortly after the middle of the month when operators will start to prepare for resumption of work. Some operators believe that the mines will be in operation by Apr. 22, but the majority believe that little coal will be mined in Ohio before May 1.

Cleveland—Contracts for transporting 750,000 tons of coal to Lake Superior points were recently distributed among Cleveland vessel managers. The contracts provide for an increase of 25 per cent. of the tonnage, if the shipper desires, by the middle of the summer. The freight rate is 30c. a ton. Independently of arrangements that have been made for floating large amounts of coal, for which contracts have not been signed here, there have been awarded independent vessel managers more than 2,000,000 tons of coal at last year's rates.

Pennsylvania

Bituminous

Pittsburg—District No. 5, United Mine Workers, voted, Apr. 11, overwhelmingly in favor of the Cleveland wage settlements. Demands which miners of western Pennsylvania will make upon the operators were formulated at the convention on Apr. 12. Operators and miners of the Pittsburg district will meet in joint conference to reach an agreement for this field. The agreement will be based on the demands approved Apr. 12 and the basis for the wage contracts reached at the interstate joint conference in Cleveland. Among the more important demands for the local field are:

Abolishing machines in extracting ribs and stumps; uniform outside day wage scale; uniform scale for slate and dead work; complete check-off for the organization for all men working in or about the mines; house rent and the price of

house coal to remain the same and not be increased because the men's wages are increased; rent to be $1 a room a month and house coal $1 a ton; no discrimination against miners for refusal to patronize company stores; where a miner is discharged or forced to remain idle through a dispute with the company, and is afterward found to have been unjustly dealt with, he is to be reinstated and paid for lost time.

California—In the face of the stand taken by the miners of District No. 5 in their convention at Pittsburg, when they agreed to remain idle until Apr. 22, Vesta No. 4, the largest mine in the district, resumed operations Apr. 11.

Washington—Options on about 800 acres of the Pittsburg vein of coal underlying several farms on the southern border of this city have been taken by C. T. Bartlett, of Washington, and the deal is expected to result in the opening of a coal mine just over the borough line. Mr. Bartlett is reported to have optioned the coal at $300 an acre.

Du Bois—The operators' association of District No. 2, United Mine Workers, took a decided stand in the joint scale conference, Apr. 10, practically refusing the scale presented by the miners and offering a renewal of the previous wage agreement for two years. In the event of this counter proposition not being acceptable to the men, the operators proposed to submit the matter to arbitration.

Johnstown—Preliminary surveys have been made and a definite route is now being mapped out for an extension of the Windber-South Fork branch of the Pennsylvania R.R. into the Shade township coal fields in Somerset County. Several local coal firms are interested in the project as they own big holdings in that field. The route will branch off the Windber-South Fork tracks at a point below Arrow. It will follow the general direction of Shade Creek and will be routed toward Central City. The extension will open for the Pennsylvania R.R., the basin in which the Shade field is situated, as far south as Berlin, an airline distance of from 25 to 30 miles.

Anthracite

Scranton—The colliery railroad lines of the Mount Jessup, Moosic Mountain and Dolph Coal Companies, independent operations at Jessup, near here, were put temporarily out of commission by a dynamite explosion on a cross-over of the railroads, Apr. 11. Sticks of dynamite were found under the rails of an Erie Railroad mine switch for a distance of 100 ft., and if they had not been found, a train crew would probably have been blown up. On Apr. 13, the Dolph company's pump runners, firemen, engineers and repairmen, who have worked during the suspension, were attacked by a crowd of nearly 100 men. The rioting is attributed by the miners' union, the colliery owners and the sheriff to a branch of the Industrial Workers of the World that has been flourishing in Jessup for several years.

Thirteen damage suits were started recently against the Price-Pancoast Coal Co. by families of victims of the Pancoast mine disaster of Apr. 7, 1911. In three of the actions $50,000 is the measure of damages fixed and in the other cases the amounts vary from $20,000 to $30,000.

The average price at New York for domestic sizes of anthracite coal for March has been determined by Commissioner Neill as $4.88. This price entitles the mine workers to an increase of 7 per cent. on the rates of wages fixed in the award of the anthracite strike commission. In the last 12 months the average monthly bonus to mine workers under the sliding scale has been about 4⅔ per cent.

Wilkes-Barre—The anthracite coal companies of the Wyoming region offer no encouragement to large coal consumers that the suspension of work at the mines will be of short duration. The Delaware & Hudson Co. recently notified the officials of the Sheldon Axle Works that if they wanted more coal they had better place their order at once.

The Prospect colliery of the Lehigh Valley Coal Co., located in Wilkes-Barre, claims the world's record for a month's production of anthracite coal. It turned out 104,000 tons during March.

Fires continue to be drawn from under the boilers and mules taken out of the mines in this region, which many think is a sure indication that the suspension of work will last longer than first expected.

Shamokin—Orders from union headquarters have called off all repair work in this district after Apr. 10. There will be no interference with the pumpmen and workmen needed to prevent damage to property until after the result of the conference at Philadelphia becomes known, when it is intended to suspend everything if an agreement is not reached. The union heads claim that some companies were taking advantage of the permission granted to do repair work to prosecute new work, which led to the order being issued.

Philadelphia—Conferences of anthracite operators and miners were opened here, Apr. 10. Representatives of the miners declined the offer of Mr. Baer, on behalf of the operators, to submit the controversy to a board of arbitration, and the whole matter in dispute was referred to a committee of four operators and four miners. So far no definite results of their deliberations have been made public, but an optimistic feeling seems to prevail to the effect that a satisfactory settlement will be reached.

Virginia

Pocahontas—The Panama R.R. Co. has awarded the contract for 2 years' supply of coal at the Panama Canal to the Pocahontas Fuel Co. The contract calls for the delivery of as much as 550,000 tons a year at $2.70 a gross ton, with a reduction of 5c. a ton should the price of coal decline during the second year.

West Virginia

Fairmont—Several large mining companies, employing nonunion labor, have announced an increase in the wages of their employees. The companies making the advance are the Consolidation Coal Co., the Davis Coal & Coke Co. and the Black-Sheridan-Wilson Co. In all about 15,000 men are affected. These companies are considered to have always treated their employees liberally, and have few labor difficulties in their respective fields.

Fayetteville—Extra police have been placed in the mining communities of Boomer, Cannelton and Marting, where race riots are feared between American and Italian miners. Feeling runs high following the murder of a bank boss of the Boomer Coal Co., who was followed to a stable by three Italian miners and shot down in cold blood. Governor Glasscock was asked to have the militia in readiness to be sent there. All the mines are idle pending the decision on the referendum vote on the Cleveland agreement.

Moundsville — When non-union men were leaving the Mound City coal mine, Apr. 9, they were attacked by a mob of 400 union miners armed with guns and clubs. Two were probably fatally injured and several others seriously injured. A riot call was sent in and the sheriff with a posse of 100 deputies, rushed to the shaft of the mine and charged the mob. Six deputies were injured in the mêlée. The company has applied to United States Judge A. G. Dayton for an injunction against interference by the strikers.

Bohemia

Karlsbad—The strike in the Bohemian coal fields, which was ordered at the same time as the British strike, came to an end Apr. 3 when the mine owners gave the miners guarantees of wage increases, although the men will not get the full 15 per cent. demanded.

Spain

Madrid—A commission representing the mine owners has not been able to reach an agreement with Premier Canalejas on the threatened strike of the coal miners. The miners in the Asturias region, failing to receive an increase of 10 per cent. in their wages, threaten to strike.

Personals

J. M. Fitzgerald, the recently elected president of the Davis Coal & Coke Co., was in Baltimore last week, after having completed a trip over the company's properties in West Virginia.

W. J. Finnegan has resigned as secretary of the Central City Coal & Iron Co., with offices in Louisville, to become general sales agent and assistant manager of the Louisville Coal & Coke Co.

J. W. McNeill, marine clerk in the offices of the Davis Coal & Coke Co., will go to New York as chief clerk to President Fitzgerald. C. C. Knobeloch will fill the position formerly held by Mr. McNeill.

George Watkin Evans has recently resigned his position as chief of coal surveys for the Washington Geological Survey, and has opened an office in Seattle as consulting mining geologist and engineer, specializing in coal.

C. S. Bookwalter, of Paducah, Ky., has been elected general manager and treasurer of a new company which has been organized to take over the property of the old Carbondale Coal & Coke Co., with mines at Hamby, Ky.

E. N. Zern, assistant professor of coal mining at the University of Pittsburg, has been elected professor of coal mining by the board of regents of the University of West Virginia to fill a position created by the recent establishment of a school of mining at this institution.

C. T. Fairburn, general manager of the southern district of the Republic Iron & Steel Co., has withdrawn from the executive committee of the Alabama Coal Operators' Association, and has been succeeded by A. H. Woodward, of Birmingham, general manager of the Woodward Iron Co.

E. M. Wadsworth, dean of the mining department, University of Pittsburg, has retired and S. A. Taylor, president of the American Mining Congress, has been elected to fill the vacancy. Mr. Wadsworth will receive a pension from the university and will probably devote a portion of his time to its affairs.

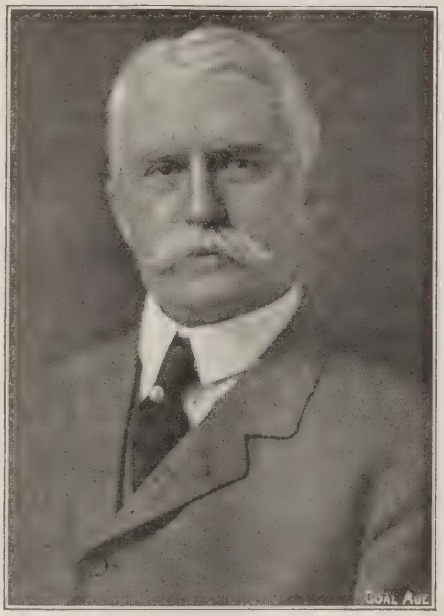
John F. Meagher, of Mulga, Ala., general superintendent of coal mines for the Birmingham Coal & Iron Co., has been appointed assistant general superintendent of coal mines for the Tennessee Coal, Iron & R.R. Co., with headquarters at Ensley, Ala. Mr. Meagher will assume his new duties at once.

Edwin Ball, of Birmingham, Ala., manager of ore mines and quarries for the Tennessee Coal, Iron & R.R. Co., has been appointed general superintendent of all the company's mines, following the resignation of Edward H. Coxe, general superintendent of coal mines and coke ovens. Mr. Coxe will remain with the company until about June 1.

Obituary

William A. Lathrop, president of the Lehigh Coal & Navigation Co., and Lehigh & New England R.R., one of the foremost men in American mining circles, died Friday morning, Apr. 12, at the City Hospital, Wilkes-Barre, Penn., following an operation for appendicitis. His condition had been critical for several days, and a number of specialists had been summoned to his bedside.

Mr. Lathrop was 58 years old. He was born in Springville, Susquehanna County, Penn., and acquired his earlier education at the schools of this town. Later, he entered Lehigh University, and in 1875 was graduated with honors as a civil engineer. He afterward took a course in mining and received his degree



William A. Lathrop

of mining engineer from the same institution.

For two or three years after his graduation Mr. Lathrop was employed in various minor capacities, both in the anthracite mines and on railroad work in the Wyoming and Lehigh districts of Pennsylvania. He subsequently became assistant to Robert H. Sayre, chief engineer of the Lehigh Valley, and filled this position with great credit for several years. Later, he was associated with Major Irving A. Stearns, of Wilkes-Barre, and for a time took over the management of an iron-mining enterprise in northern New Jersey.

In 1881, when the Southwest Virginia Coal Co. required a superintendent and mining engineer to open up its properties in southwestern Virginia, Mr. Lathrop was selected for the position. He started the mines which have since become the center of the Pocahontas field, and laid out and built the present town of Pocahontas.

After several years of labor against great difficulties in this pioneer work in Virginia, he returned to Pennsylvania in charge of the bituminous mines of the Lehigh Valley Coal Co., at Snowshoe, in Center County, and in 1888 was made superintendent and general manager of all the Lehigh Valley mining operations, succeeding the late Frederick Mercur. Mr. Lathrop remained at Wilkes-Barre in this capacity until 1902, when he resigned to take the presidency of the Webster Coal & Coke Co., operating in central Pennsylvania, and later was made president of the Pennsylvania Coal & Coke Co. When this company leased its mines and lands to other interests, he became president of the Lehigh Coal & Navigation Co., with headquarters in Philadelphia, succeeding Lewis A. Riley.

Mr. Lathrop was a member of the state commission, appointed by Governor Tener, a few months ago, to devise a plan for the protection of the surface of the anthracite region from damage by mine caves. He was a trustee of Lehigh University, president of several coal companies, a director of the People's Bank, of Wilkes-Barre, and of the Fourth National Bank, of Philadelphia, a member of the American Institute of Mining Engineers, the Mining and Metallurgical Society, the Union League, University, Art and Downtown clubs, of Philadelphia, the Westmoreland Club, of Wilkes-Barre, the Railroad Club, of New York, and the Pennsylvania Society of Sons of the Revolution. Although in recent years much of his time was spent in Philadelphia, Mr. Lathrop made his home at Dorranceton, near Wilkes-Barre, Penn. He is survived by his wife and one daughter.

Construction News

Birmingham, Ala.—Plans are being prepared by the Corona Coal Co. for improvements to its property at Corona and elsewhere, involving an expenditure of about $300,000.

Zanesville, Ohio—R. P. Dutro, of Crooksville, has leased 300 acres of coal land in Perry County and will develop the property by opening a mine some time this summer.

Louisville, Ky.—The Perry County Coal Co., which has been organized by Cincinnati interests, will begin mining operations at Viper, Ky. A mine is to be opened in the immediate future.

Wilkes-Barre, Penn.—The contract for building a new breaker to replace the Paine breaker, which was burned down some time ago, has been awarded to W. L. Moore, of Luzerne. Work will be started at once.

Louisville, Ky.—The Consolidation Coal Co., of Baltimore, Md., has awarded a contract for the construction of 1000 buildings at the new town of McRoberts, Ky., to the Nicola Construction Co., of Pittsburg. Work is in progress.

Charleston, W. Va.—The Kimball Pocahontas Coal Co., of Kimball, W. Va., has been incorporated, with $100,000 capital, to operate in the Brown's Creek district of McDowell County. H. D. Hatfield, Eckman, W. Va., is one of the incorporators.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

While there has been no further recession in prices, the coal market is undoubtedly at a complete standstill. This is due to the unexpectedly short duration of the bituminous suspension, the heavy stocking and the general belief that a further decline in prices is inevitable. Most of the large consumers and dealers were prepared for a protracted shutdown at the mines, with the result that the former are showing no disposition to buy, while the latter are anxiously seeking a market for their product, acquired in many instances at a high figure.

In the East there is little or no business being done in the open market, the movement being confined almost entirely to contracts. With the bituminous agreements settled, interest is now centered on the anthracite conferences, and it is believed that a resumption at the hard-coal mines will not be effected before May 15. While quotations have eased off in some sections, there is so much high-priced coal on hand that wholesalers are making every effort to hold the market at the present high level. There is considerable activity in the Pittsburg coke market, in which the suspension over the Easter holidays developed a temporary but pronounced shortage.

A general holiday is in effect in the Ohio trade, there being but few arrivals, which are selling at a low figure. The suspension has resulted in the consumers using up much of their surplus coal, which, together with the shortage in the Northwest, has engendered a strong feeling of optimism over the outlook.

In the Middle West the trade generally is dull and quiet, while at Chicago heavy tonnages which accumulated on demurrage, were forced on the market and caused a ruinous slump in prices. Rumors of a possible strike in the Far West next fall have had a stimulating effect on the markets there.

Boston, Mass.

The week has shown a sagging market, with bituminous easing off to nearly normal prices, and anthracite bringing much reduced premiums. This, in the face of no supplies on hand, and a partial suspension at the soft-coal mines, shows the extent to which buyers are waiting. Shipments from the Georges Creek field have narrowed the demand for the Pennsylvanias, and quotations on the latter vary according to the anxiety of the shippers to sell. There is little present interest in bituminous, more than enough to carry over into June, when everybody is predicting an easy market, both as to coal and freights.

The loading situation on Pocahontas and New River, at Hampton Roads, is not clearing as fast as was expected; boats are still taking two weeks and more to load. The agencies are apparently waiting for the market to settle down before attempting to contract for the new year. Efforts in that direction seem to be confined entirely to shippers of Georges Creek.

In anthracite the trade is at a complete standstill. The companies are cleaning up loose ends of stock here and there, while the available supply of new arrivals has practically disappeared. Quotations are off considerably from what they were, and there appears to be a feeling that the suspension will only be of short duration. The reports of the conferences are followed here with much interest.

Soft coal all-rail is slow again; the volume of speculative shipments was so large that the consumers are well satisfied with the situation at present. Prices have been forced down to nearly normal for the cheaper grades, and there has been no difficulty in obtaining consignments of arrivals at the transfer points.

Freights are much easier. Dollar freights from Hampton Roads to Boston are in sight, and in Reading transportation from Philadelphia the rate had been put down to about $1.20@1.

Current prices are as follows:

Clearfield, f.o.b. mines	$1.50@1.25
Clearfield, f.o.b. Philadelphia	2.75@2.50
Pocahontas, New River, f.o.b. Hampton Roads	3.25@3.85
Georges Creek, f.o.b. Baltimore	2.80@2.95
Georges Creek, f.o.b. Philadelphia	2.87@3.05

New York

The situation in the New York market continues unchanged. The trade is apparently undergoing a period of readjustment, made necessary by the unexpectedly short duration of the suspension in the bituminous fields. Interest is now centered entirely on the anthracite conferences being held in this city, and should these not result in an agreement, it is probable there will be a renewed activity in trade circles. A shortage in anthracite will materially effect the bituminous consumption, so that progress of negotiations is being keenly followed by both branches.

In bituminous the arrivals are good, and the trade is quiet, with only a few transactions being recorded. There appear to be large tonnages of the low-grade fuels on the market, and these are exerting a depressing influence on prices, which are now quoted around $3, f.o.b. Mines shipping this market are working under a fair to normal capacity. The railroad movement is good, and while the dealers are short in supplies, the consumers generally are well stocked.

The anthracite trade is at a complete standstill, with nothing coming in and little or no demand. An acute shortage developed in rice, while supplies generally are estimated at less than one-tenth normal.

Current wholesale quotations here are as follows, per ton:

Broken	$5.00@5.25
Egg	5.00@5.25
Stove	5.50@5.75
Nut	5.20@5.50
Pea	3.75@4.25
Buckwheat	3.50@4.00
Rice	2.50@3.25
Barley	1.90@2.25

Philadelphia, Penn.

The trade in this vicinity is about the same as last week, which is not saying a great deal, as the very optimistic reports that the newspapers are making about a favorable settlement of the trouble between the operators and miners, is causing householders generally to postpone any purchases of coal unless absolutely necessary. The dealers are fairly well stocked, that is, with the domestic sizes of coal, but declare that business is exceedingly poor.

No coal is being sent to market, and there is nothing offering with the exception of some that is in the hands of speculators, who are asking, but in very few cases receiving, exorbitant prices. As a whole, the consumers are fairly well supplied with fuel, and with the coming of warm weather, when most fires will be drawn, are loth to worry about the situation. It is still in doubt what the final outcome of the difficulty will be, and what the adjustment, if any, will amount to. It is believed the two most important items of the miners' demands, recognition of the union and increased wages, are the stumbling blocks, and it almost goes without saying that an increase in the scale of wages will bring about an addition to the prevailing prices for coal.

Already it is rumored that stove size is likely to be put on a parity with chestnut, or in other words, an advance of 25c. over last year, but the wholesale operators neither confirm nor deny this, taking refuge in the statement that present prices, or the March circular, will prevail, until some adjustment of the trouble is brought about. Predictions are freely made that it looks now as though it would be the middle of May before resumption of mining.

Pittsburg

Bituminous—There has been practically no coal market the past week. The operators have no coal to sell and consumers are fairly well provided, having as a rule laid in larger stocks than necessary to tide them over the suspension, which proves unexpectedly short. While official warrant is not yet available, it is expected the mines will resume next Monday, as presaged in last week's report.

The Lake shipping season will open May 1, when the new rate of 78c. on cargo coal to the lakes goes into effect, against the old rate of 88c. Many contracts will probably have been closed before that time, but operators do not admit that any have been made thus far. Expectations are for a much better movement this year than last, as last year's movement was light and the hard winter cleaned up stocks in the Northwest very thoroughly. The Pittsburg district does not, however, expect to obtain a much larger percentage of the total business than in the past couple years.

Connellsville Coke—Coke has been higher the past week, partly on account of increased production cost through the advance in wages and partly through decreased production owing to celebration of the Easter holidays. It is estimated that last week's production was about 60 per cent. of normal, production in the first two days being not over 30 per cent. of normal, while the two days following was somewhat low also.

Very little coke has moved, but $2.75 and $2.85 has been freely paid for small prompt lots, while occasionally a few carloads brought still higher prices, when the seller could assure spot shipments by giving car at the time of making sale. There is no market on contract furnace coke, neither buyers nor sellers having gotten down to business. There is little contract business to be closed for second quarter, but a considerable tonnage runs out July 1. We quote: Prompt furnace, $2.75@3; prompt foundry, $3@3.25; contract foundry, $2.65@2.75.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Apr. 6 at 415,464 tons, an increase of 2000 tons, and shipments at 4339 cars to Pittsburg, 6605 cars to points West and 1370 cars to points East, a total of 12,314 cars, a decrease of 136 cars; shipments East, however, increased 300 cars.

Baltimore, Md.

The Baltimore market eased off considerably during the past week, prices being lower and the demand less active than heretofore. This is due to the fact that many consumers stocked up to protect themselves, and that they now find a goodly supply on hand, with little possibility of a serious tie-up in either the anthracite or bituminous fields. The few who decided to take chances in the market in the event of a strike, are apparently not doing any buying, they believing that prices will go much lower than they are at present.

One large operator declared that, so far as his company was concerned, he found it difficult to sell coal at the prices which prevailed before the undue activity set in, as the result of strike conditions abroad and the unrest in labor circles here. At the present time, there is a large amount of coal in the market, and shipments are being made with the greatest dispatch. The car supply is adequate.

Buffalo, N. Y.

The market is very quite here and this is likely to continue for some time or at least till an understanding is reached with the miners. So little progress has been made in that direction as yet that it is impossible to make any prediction as to when business will return to normal.

There is just enough bituminous production to bring prices down close to last winter's figures. Some incautious operators and jobbers have found themselves with considerable coal on hand for which there is no market and more or less car service has been paid. One successful operator, however, reports that he is still getting about 20c. a ton more for his present small output than he was able to get last winter and he is satisfied, though it does not appear that many are doing as well.

Quotations are not much easier to make than they were last week, for prices, though lower, are not at all uniform. One dealer ridicules the prices that another claims to be getting. It is at least agreed that slack and coke are very strong and much higher than they were a year ago. There is no slack making for the lake trade and the coke regions are very short of men, so both should be strong for some time yet.

Nearly former quotations of bituminous are still in effect as follows: $2.60 for Pittsburg three-quarters, $2.50 for mine-run and $2.25 for slack, with coke up to $4.75 for best Connellsville foundry. Allegheny Valley coal is commonly about 25c. lower than Pittsburg, though the difference is not so closely maintained as it sometimes is.

There is next to nothing doing in anthracite. Shippers are getting a few cars now and then and the few consumers who are in the market are taking it at full prices, or at a premium in case of independent stores. The predictions that mining would be resumed soon after the middle of April are not heard now. Not a few coal men are now looking for an obstinate strike before the differences are settled.

Cleveland, Ohio

A general holiday has been in effect during the past week in coal trade. A few straggling cars of coal have come into this market but there was considerable difficulty in disposing of it at any price; fortunately however, the quantities were small, as no doubt this coal was purchased at a high rate just prior to the suspension. At this moment every indication points to the miners going to work in the next week; fully 90% of the men have accepted the two-year scale, proposed by the Cleveland conference of miners and operators, and reports show that work will soon be resumed at the mines.

According to the operators, 1912 promises to be a banner year in the lake trade, owing to the unprecedented cold weather in the North last winter. It is said that every pound of coal at the upper lakes has been disposed of, and with the docks pretty well cleaned up, operations in this trade will start briskly as soon as it is known definately that the lakes are free from ice.

There seems to be a much better feeling shown throughout the country, and operators and jobbers are expecting quite a business revival the coming year. Up to the present there has not been any shortage of coal reported by manufacturers or others, as everybody stocked up in anticipation of a suspension, and it is not expected that there will be any great demand for at least two weeks.

There is very little demand for domestic, as the season for that grade is about over. At present no prices are being quoted owing to the uncertainty, but established prices will probably be made during the week.

Columbus, Ohio

The coal market in Ohio during the past week has been at a standstill. The trade has been waiting the announcement of the result of the referendum vote of the United Mine Workers of America on the wage-scale matter, and unofficial reports show that it has been carried but it will be at least a week and possibly two weeks before the mines in the Ohio fields are again running.

In the meantime, steam users are consuming their surpluses, stored in preparation for the suspension. There is no report of suffering or great inconvenience in any quarter and the supply will un-

doubtedly be ample to last until mines have resumed. Many of the railroad companies have thousands of tons stored, sufficient to last several months.

There are bright prospects for a large Lake trade, as practically no stocks will be carried over in the Northwest. There are also good indications for an active steam business, since there will be little in storage at the beginning of May. The general tone of the market is satisfactory, and operators are looking forward to a good year. It is believed that prices will be somewhat stiffer during the summer than was the case last year.

Operators are taking advantage of the suspension to prepare their mines for the renewed activity when the wage matter is finally settled. A number of new mines will be opened in the Ohio fields, and preparations are being made for an increased output.

One of the features of the trade which will be given attention soon is the domestic demand. Stocks in this branch are generally small, and the stocking season is expected to produce a good demand for the larger sizes. Dealers are already placing their yards in shape for the opening of the stocking season.

Prices which can be said to prevail in Ohio fields are:

Hocking Valley	
Domestic lump	$1.50
¾-in.	1.35
Mine-run	1.15
Nut	1.20
Nut, pea and slack	0.85
Coarse slack	0.65
Pittsburg No. 8	
¾-in	$1.05
Mine-run	1.15
Coarse slack	0.75
Pomeroy Bend	
Domestic lump	$1.55
¾-in.	1.35
Nut	1.25
Mine-run	1.15
Nut, pea and slack	0.80
Coarse slack	0.70
Kanawha	
Domestic lump	$1.50
¾-in	1.30
Mine-run	1.10
Nut, pea and slack	0.80
Coarse slack	0.70

Nashville, Tenn.

The market in the west Kentucky field is in a very healthy condition. This is accounted for by the fact that the union fields have not definitely arrived at a basis of settlement yet, and there seems to be quite an uncertainty as to when they will do so.

The L. & N. R. R. are taking quite a tonnage of coal from all the mines. In view of the fact that the union mines are not working, it is giving the nonunion quite a heavy tonnage which they are very glad indeed to have, as business would naturally be a little quiet if it were not for this, although there is a fair demand for steam coal.

Domestic business is practicaly dead, and it is almost impossible to move any lump coal; consequently there is a very small amount of screenings being produced and the demand for them, as well as the prices offered, are very much greater than has ever been known in this section. Some of the steam plants that are dependent upon screenings, on account of their stokers, are crushing mine-run at an enormous expense. The indications are that prices will be a little better the coming season.

Chicago

The recent disturbances in the coal-mining situation have resulted in a difference of 35 to 60c. between the spot and mine prices on all kinds of steam coal; the average is probably close to 50 cents.

Large shipments have arrived at Chicago, and a very substantial amount has accumulated on demurrage. By forcing this coal on the market, prices have been brought down to from 90c. to $1 a ton below the price paid by the middleman.

There is no particular demand for smokeless lump and egg, and the price is $1.50 at the mines. It has been the experience of dealers that anything on track, with the exception of smokeless mine-run, had to be sacrificed in order to move it. It is understood that the Lake shipping interests will soon reach a decision that the market warrants a price about 10c. a ton over that of last year.

Prevailing prices at Chicago are:

Sullivan County:	
Domestic lump	$2.37@2.62
Steam lump	2.17@2.27
Screenings	1.72@1.77
Springfield:	
Domestic lump	$2.32@2.57
Steam lump	2.02@2.22
Mine-run	1.92@2.02
Screenings	1.67@1.72
Clinton:	
Domestic lump	$2.27@2.52
Steam lump	2.07@2.17
Mine-run	1.87@1.97
Screenings	1.62@1.67
Pocahontas and New River:	
Mine-run	$3.15
Lump and egg	3.55

Coke—Prices asked for coke are: Connellsville and Wise County, $4.85; byproduct, egg and stove, $4.80; byproduct, nut, $4.50; gas-house, $4.85.

Indianapolis

The coal trade in this state is almost at a standstill, owing to the mines, with few exceptions, being closed. The suspension of work is delaying the dealers here and in other cities from the putting into effect of the summer schedule, which averages about 10% less than the winter. The reduction usually comes in April, but owing to the fact that the greater part of this month will be gone before an agreement between the miners and operators can be ratified, there is little chance of the summer rates going into effect until next month, and perhaps later. It is pointed out that the retail dealer has on hand the higher priced coal bought during March, and until the mines open and a reduction is made there is no inducement to summer buyers.

The 5 cents on the ton allowed in the new agreement, even if ratified, is not expected to affect summer prices to any great extent. A number of towns and cities in the state are face to face with a coal famine. In order to avoid closing down factories, the suspension of mining cannot be terminated any too soon.

St. Louis, Mo.

There is no business at all in the St. Louis market, and there is still a considerable tonnage of coal held on track at the mines, while some of the operators on the Illinois Central who stored coal on the ground are now loading it on cars, but there is practically no demand. There is nothing to gage prices by, as the operator will take anything that is offered.

Indications are that the mines will not resume operations now before the first of the month, and possibly not then. There is a small tonnage of smokeless moving in, but it is in excess of the demand, and coke is moving very slowly. There is nothing to indicate that conditions will improve for the next 10 days, as the stock of coal in storage is ample to take care of requirements for practically 30 days yet.

Spokane, Wash.

A general tie-up in the coal fields of Western United States is threatening Washington, Montana, Wyoming and Colorado, according to statements made by local dealers at Spokane. The agreements between the miners and the operators of this district will expire in the summer and the fall, and there seems to be ground for the belief that it will not be possible to effect a settlement. According to E. F. Waggoner, of the Union Fuel & Ice Co., the wages paid by the operators in this territory is the highest mining scale in the United States, and it is believed by nearly everyone that the scale should be reduced. However, the entire situation will depend upon the outcome of the strike in the East.

Although the dealers are laying in a good supply in case a strike does come, they have not changed their prices since last November.

San Francisco

The arrivals of coal by sea for March totalled 41,390 tons, of which 31,402 tons were foreign, viz., 30,372 tons were from British Columbia and 1030 tons from Australia. The balance consisted of one cargo, 5160 tons, of Pocahontas for the U. S. Navy, and two cargoes, 4829 tons of steam coal, from Seattle, for bunkering the navy's coast steamers at this port.

As a whole, the stock situation has materially improved during the past month. Of the British Columbia product, some

25,000 tons only are available for this market, one cargo of over 5000 tons being for transshipment to Alaska. With but 1030 tons of Australian coming in, considerable inroad was made on the supplies, and with but 11,000 tons afloat, delivery of which will be spread over the next three months, there will be none too much of this fuel in the market.

The supply of Rocky Mountain coal has been fairly good, but the dealers are loath to buy except from hand to mouth, since on May 1 a reduction of 50c. per ton off the mine price will come into force. During the past week there has been little, if any, change in the movement of coal. The weather has been mild, and consequently demand for house fuel has been light.

Current rates to the trade are as follows, per ton:

Wellington (British Columbia)	$8.00
Pelau Main (Australian)	8.00
Rocky Mountain	8.50
Cumberland	12.50
Anthracite (Pennsylvania)	15.00

Production and Transportation Statistics

Chesapeake & Ohio Ry.

The following is a statement of the coal and coke traffic over the lines of the C. & O. Ry. for February and eight months ended Feb. 29, 1912, in short tons:

Destination	February	8 Months
Tidewater	299,459	2,605,213
East	190,655	1,477,771
West	971,416	7,451,907
Total	1,461,530	11,534,891
Coke	17,180	135,240
From Connections		
Bituminous	17,650	153,890
Anthracite	4,742	26,646

Norfolk & Western Ry.

The following is a statement of commercial and company coal from mines in the N. & W. Ry. for the month of March, in short tons:

Field	Commercial	Company
Pocahontas	1,061,465	99,501
Tug River	141,582	42,665
Thacker	186,395	57,971
Kenova	62,018	8,316
Clinch Valley	116,581	9,265
Total	1,568,041	217,718

The following is a statement of the coal and coke tonnage from mines on the N. & W. Ry. in the State of West Virginia, for the month of March, 1912:

From	Tipple Coal	Total Coal
Pocahontas	20,344	1,112,468
Tug River	3,378	184,247
Thacker	5,176	244,366
Kenova	6,279	70,334
Total	35,177	1,611,415

Note—Total shipments of coke, originating entirely in the Pocahontas field amounted to 128,816 tons.

Imports

Imports of coal into the United States for February, 1912, totaled 118,921 tons as compared with 133,051 tons for the same month last year. The imports were almost entirely bituminous and 111,669 tons came from Canada, Australia and Tasmania being the next in importance with 6256 tons.

Various Railroads, Rivers and Canals

The following is a comparative statement of the fuel movement on various railroads, rivers and canals for January, 1911-12[1]:

Railroads	1911	1912
Baltimore & Ohio[2]	2,885,330	3,078,209
Buffalo, Rochester & Pittsburg[3]	692,440	755,436
Buffalo & Susquehanna[3]	174,685	174,358
Chesapeake & Ohio[2 4]	1,530,710	1,548,881
Huntingdon & Broadtop Mountain[2 3]	108,481	99,612
New York Central & Hudson River[3]	770,438	769,730
Norfolk & Western[2 3]	1,705,256	1,819,588
Pennsylvania (east of Pittsburg & Erie)[2 5]	5,569,804	5,562,831
Pittsburg & Lake Erie[2 5]	1,088,198	1,415,301

Wabash, Pittsburg Terminal Ry	5,931	2,156
Kanawha & Michigan Ry		17,526
Total	1,423,060	1,962,760

Exports

Exports of coal from the United States for February of the current year were 927,339 tons as compared with 931,797 tons for the same month last year, both figures being exclusive of bunker or fuel coal laden on vessels in the foreign trade. Exports of anthracite for February this year were 231,684 tons as compared with 219,831 tons for the same month last year. The total exports of bituminous for February, 1912, were 695,655 tons as compared with 711,966 tons in February of last year, both figures being exclusive of bunker or fuel coal laden on vessels in the foreign trade. More than one-half of the total exports were shipped to Canada. Total bunker or fuel coal laden on vessels in the foreign trade was, for February of the current year, 527,901 tons as compared with 496,602 tons for the same month last year.

Foreign Markets

Germany

The following is a statement of the production, imports and exports in the German Empire for the month of February, 1912, in metric tons:

	Production	Imports	Exports
Coal	14,644,304	642,086	2,721,612
Lignite	6,506,749	570,991	4,239
Coke	2,271,282	41,492	371,454
Briquettes	1,910,639	16,815	207,088

Financial Notes

Among stocks of other companies held by the Consolidation Coal Co. are 13,500 shares of the Northwestern Fuel Co., common stock, 2700 shares Northwestern Fuel Co., preferred stock, and 5011 shares of the Metropolitan Coal Co., common stock.

Details of consolidation of the Birmingham Coal & Iron Co. and the Woodward Iron Co., of Alabama, into the Woodward Iron Co., formation of which is a step in the renewal of the $6,239,200 joint collateral trust notes of the Atlanta, Birmingham & Atlantic R.R. and the Atlantic & Birmingham Construction Co. have been completed. Value of ores and coal properties of the new corporation is $124,435,100. Estimated coal holdings are 380,109,000 tons, valued at $38,010,900.

Indications are that Colorado Fuel & Iron Co. will show a surplus for the year ending June 30 of something like $1,500,000. That would be a substantial improvement over last year, with its surplus of approximately $1,260,000, and an especially fine showing in view of the depression in the steel industry and in comparison with earnings of other steel companies. Earnings for eight months of the company's fiscal year are about $126,000 ahead of last year. This corporation was one of the pioneers in the installation of openhearth furnaces for the manufacture of rails in place of the bessemer process, and the quality of its output has a wide and favorable reputation. Its rail mills are operating at fullest capacity, and orders on the books at present are for capacity nearly 12 months ahead.

The newly formed Woodward Iron Co. in Alabama will have $13,000,000 capital stock, of which $3,000,000 is 6% cumulative preferred and the balance common, and $25,000,000 5% 40-year sinking fund bonds, of which $13,500,000 will be issued. Of the $13,500,000 bonds which mature Jan. 1, 1952, $2,000,000 will be issued to retire a similar amount of first mortgage 5% bonds of the Birmingham Iron Co.; $9,000,000 to pay for properties acquired; $2,500,000 for immediate improvements and expenses of consolidation and $11,500,000 will be reserved for future additions and betterments. The Birmingham Iron Co. bonds are redeemable at 105 and the premium, as well as discount on bonds sold, is to be paid as an expense of consolidation. The Woodward Iron Co., of Alabama, one of the principals in the consolidation, has no notes or debts outstanding except current operating liabilities.

COAL AGE

Vol. 1 NEW YORK, APRIL 27, 1912 No. 29

So far as unionism in coal mining is concerned, Illinois is the star performer of all states in this country. Last year, in compliance with the check-off system in force in that commonwealth, coal operators paid more than $650,000 into the treasury of the mine workers. Practically every one of the 70,000 colliery employees in Illinois is a member of the union. In the anthracite field, where the "check-off" has not been forced on the operators, a recent report of the U. M. W. of A. showed an enrollment of only 14,000 out of 170,000 hard-coal miners.

It is evident therefore, why the leaders of united labor desire anthracite recognition, such as would be conceded in the proposed check-off system. The difference to them is a matter of increasing their annual income in the hard-coal regions from $130,000 to more than a million and a half. What could they not eventually accomplish if provided such a sum to work with?

The anthracite operators have the Illinois mine owners set before them as an example of what will happen when labor gets the upper hand. Conditions in Illinois have become such that John Walker and his lieutenants practically dictate the policy of the industry in that state. Men cannot be discharged, machinery introduced, nor improved methods inaugurated unless the act is labeled with a union endorsement.

Illinois has 850 mines, operated by 260 companies, and it is this condition that has brought about a policy of "every man for himself, and the devil take the hindmost." As a result, mine owners have lacked unity of purpose, and coal mining in that state has been brought to a deplorable pass. The union is adding to the present burden of the operators little by little, not seeming to realize that by hampering and weakening the employer, the laborer himself will fail to prosper. With highest wages and most favorable working conditions, the Illinois miners receive less per year than do coal hewers in many other fields where the rights and welfare of the men are supposed to be less properly safeguarded.

Unlimited success, therefore, is the danger rock on which the miners' organization and the labor movement as a whole will dash itself to pieces. Human nature is very much the same in the average of mankind. Just as the good swimmer, glorying in his superb strength and skill, goes furthest from shore and perishes through overestimating his own power, so capitalism through the abuse and misapplication of wealth became top-heavy and tumbled from its apparently safe foundation. In like manner, labor unions are piling success on success, using each victory as a stepping-stone to a new demand, until at last the structure built with so much pride and hope will collapse because the architects bungled the plans and ignored the necessity of observing established economic facts.

No matter what color glasses we look through, everyone must recognize that wages cannot be larger than the product of a man's labor; in fact, they must always be less than the product—big enough to give the capitalist his due returns and the employer his living profits. When workmen, acting individually or collectively, attempt by force to refute this certain principle of wages, the result can be no more successful than would be an effort to overthrow the law of gravity.

Production will ever be the only true measure of a workman's pay, and in accord with this idea, the wages-class are entitled to the immediate benefit of every improvement in science and art, every discovery of resources in nature, and every advance in their own industrial character. However, the doctrine of *Laissez faire*, which teaches that the spontaneous action of individuals, each seeking his own interest on his own instance, will attain the best results, is mischievous, and only applicable in special cases. Acceptance of such a principle is certain to bar the way to advances in the industrial condition of mankind; in brief, such a rule, like fire or water, is a good servant but a bad master.

In conclusion, therefore, we uphold the unionization of workingmen when they combine to prevent industrial degradation, and to better their condition in life, but we deprecate the unwise exercise of great power, such as caused the head of a powerful labor organization to declare in New York this week, that unless the demands of his union be granted, he would shut off the food supply of our greatest city in less than seven days. If labor leaders could only discern that the chief danger to their cause lies in the errors of their own ways, the future of the wage earner would be brighter and safer than it is today.

Continuing this line of thought, next week we shall deal with compulsory arbitration, and the recent advances made by workingmen in New Zealand, the world's social experimental ground.

The Sheridan, Wyo., Coal Field

By Jesse Simmons *

This is the second and concluding article describing operations in this field. The Carney Coal Co., one of the properties dealt with, has a mine with a capacity of 4000 tons per 8-hour shift. A detailed account of the Acme Coal Co.'s plant will follow at an early date.

*Deadwood, S. D.

The Carney Coal Co.

The property of the Carney Coal Co. is on the northerly side of Tongue River, embracing 2600 acres of patented land owned by the company and 640 acres of leased land. The Carney bed, as it is locally known, has been developed here to the greatest extent of any point in the district. The mine is opened by two drifts in the river bluffs, about a quarter of a mile apart. The surface plant is one of the most complete in the Sheridan field, comprising two tipples, one of which is of steel and concrete throughout; the other tipple is of frame construction and well equipped. The coal is worked by undercutting with electric chain machines, and broken down to a shale parting which gives a thickness of approximately 10 ft. of clean coal. The plant has a maximum capacity of 4000 tons in an 8-hour day. The mine is worked in 30-room panels, rooms being driven on 45-ft. centers to a length of 300 ft.; electric haulage is used.

The camp, known as Carneyville, includes 163 houses, which were constructed by the company, and are leased to the employees at a nominal rental, a church, store, office building, etc. Every room in the village has electric lights, and every home is supplied with running water from a system maintained at the power plant. C. B. Seymour, Carneyville, Wyo., is general manager.

The Kooi Mine.

Peter Kooi, of Kooi, Wyo., is the owner and manager of the property bearing his name, near the western extremity of the Sheridan field, on the southerly side of the Tongue River, two miles west of the Monarch mine. The Monarch seam is mined, the bed showing practically the same thickness as in the Monarch property, which has been described, and the coal is mined on the same system.

Horses haul the coal from the rooms to the sub-partings, and a Westinghouse 6-ton electric-locomotive takes it to the main parting, from whence a tail-rope haulage system is used to transport it to the tipple. From the pit mouth inward for a distance of 150 ft. the pitch is 4%, and from that point the entry follows the seam on a pitch of about 1.5%. The tail-rope haul is 1500 ft. in length, with a Flory engine for furnishing the power.

A Norwalk 24x24-in. compound, 2-stage, air compressor furnishes air for the 7 Harrison punchers which are used for undercutting the coal. Some modifications are now being made, following the adoption of electric power secured from the Sheridan Electric Light & Power Co. The mine has a capacity of 2000 tons per day during the winter, and Mr. Kooi is proud of the fact that he has done this with a total of 102 mine cars.

Surface Equipment at the Monarch Mine, in the Sheridan District

The Model Coal Co.

Between the Acme and Carney mines, the Model Coal Co. is opening and equipping a new property on the Carney seam, the only shaft mine in this portion of the district. The opening is made by a shaft 12x24ft. and 123 ft. deep. The shaft is timbered with 12x12-in. and 10 x 10-in. square timbers, backed by 4-in. lagging. In addition a sump 12 ft.

in depth has been put down below the coal.

An electric hoist of 100 hp. using alternating current at 440 volts, will be used to hoist the coal. A 12-ft. Guibal fan, operated by a 35-hp. alternating current motor, will furnish air. Electric, shortwall, chain machines will be used for undercutting. Mine water will be handled with a motor-driven pump. A re-screening plant will be erected to prepare the smaller sizes of coal, and trackage, scales, etc., for handling 1000 tons per 8-hour day are being installed. The transformer house will contain transformers for stepping the power down from the line voltage to 440 volts, and a 1000-kw. motor-generator set, developing a 250-volt current for the mining machines, etc. Power is purchased from the Sheridan Electric Light & Power Company.

Surface Plant of the Carney Coal Co.

Puncher Air Machine in the Kooi Mine

The Model Coal Co. is incorporated under the laws of the state of Wyoming. The property is leased under a royalty per ton of coal extracted. The president is Frank W. Smith, Detroit, Mich.; treasurer, John Peters, Williamsport, Penn.; general manager, Stewart Kennedy, Carneyville, Wyo.

The Acme Coal Co.

The Acme Coal Co. operates two properties, the Nos. 1 and 2 openings, which are on a tract of land near the western edge of the field, and the No. 3 opening, which is at the present time the most northeasterly development in the district; the properties are about three miles apart. Nos. 1 and 2 are operating in the Carney seam, and the No. 3 workings are in the Monarch. No. 3 is a new property, and a splendid plant is being rapidly completed and put in shape to make an excellent grade of coal for years to come, while the ultimate end of operations at Nos. 1 and 2 can be but a few years distant.

No. 3 is a drift mine, the entry being made in the northerly bluffs of the Tongue River. The coal is mined by undercutting with Jeffrey mining machines, of both breast and longwall types, operated by 250-volt direct current. The coal is hauled from the main partings to the yards, which are a quarter of a mile from the pit mouth, by Jeffrey electric-locomotives. Here the cars are picked up by a cable-haul and delivered to a second cable-haul which takes them up an incline approach to the top of the tipple, 49 ft. above the yard tracks, where they are dumped in a crossover dump.

The coal, dumped from the mine cars, enters a bin with a movable bottom, by

View of Town and Mine at Carneyville, Wyo.

which it is fed to a shaker-screen of 3000 tons per 8-hour day, capacity. This screen has both lateral and longitudinal motion—something new to the Sheridan district—and makes a very clean product. From this screen coal may be loaded into either open- or box-cars, an Ottumwa loader being used for loading the latter. Covering the screen with steel plates makes it possible to dump mine-run.

The screen has 6-in. circular openings and the product passing over it is the standard lump of the Sheridan district. That portion passing through is either loaded into open cars or carried on a 30-in. belt-conveyor to the re-screening plant. This plant contains a revolving screen 24 ft. long and 6 ft. in diameter. For one-half of this length it is surrounded by a section 7 ft. in diameter. The screen openings are as follows, reckoned from the upper end: 1-in. for the first 12 ft.; 2-in., for 6 ft., and 3½-in. for the remaining 6 ft. The 12-ft. section of outer screen surrounds the inner section of equal length having 1-in. apertures, and has ½-in. openings. The screen is approximately 65 ft. above the ground, and underneath are bins with a capacity of 500 tons. On this screen are made slack, pea, nut and egg. The latter product is the portion coming from the main tipple which passes over the largest openings in the revolving screen. The entire tipple and re-screening plant is operated by electric motors.

Power is secured from the Sheridan Electric Light & Power Co. whose plant is a few rods away from the tipple. This plant is equipped with 3 Heine water-tube boilers having Roney stokers, and 2 Westinghouse Parsons turbines, each of 1250 kw. capacity generating a 2300-volt, 60-cycle, 3-phase, alternating current. The current is stepped up to 22,000 volts for transmission to the city of Sheridan and surrounding mines.

The product from Nos. 1 and 2 mines is dumped over a frame tipple, situated covenient to both openings; both are drift mines. Electric undercutting and electric haulage are used. The plant has a capacity of 1000 tons in 8 hours. Here, also, a well built camp has sprung up to afford accomodation for the employees. A. K. Craig and Ora Darnall are the owners of the capital stock of the Acme Coal Co., both making their headquarters at Acme, Wyoming.

Mine Registration and Checking

By W. A. Davidson*

At the Coleman mine of the International Coal & Coke Co., a loose-leaf record is kept of all employees, past and present, and a most satisfactory system of checking the men in and out of the mines has been installed. The registration and checking systems, the check board, and methods of operation are here described in detail.

*Superintendent and mine manager, International Coal & Coke Co., Coleman, Alta.

At the mines of the International Coal & Coke Co., at Coleman, Alta., Canada, all the underground men are hired by one person, who, on engaging a man, gives him a slip, directed to the timekeeper, showing his name, occupation and the time at which he is to start work. The timekeeper then registers the new employee in the "Mine Register," which is required to be kept in accordance with the Canadian coal mines act. The register at this particular mine is in the form of a loose-leaf ledger, allowing a leaf to each man. When the leaf is filled in, it is inserted in the binder alphabetically. This record is of the form shown in Fig. 1.

If the workman can write, he is required to sign the form himself and the balance is filled in by the timekeeper. The record is almost self-explanatory. "Dependents" and "Dependents' Address" are recorded for convenience in case of serious accidents and for information required in connection with the workman's compensation act, which is in force in Alberta.

The employee is next given an aluminum check with a number on it, called the "identification number." He is instructed to carry this check at all times and is told that it will be necessary for him to present it on pay-day before receiving his pay, and to return it on leaving the employ of the company; also that if lost he will be held responsible for it.

When the man leaves the employ of the company, the date of his time slip is marked on the register and the leaf is removed to a separate binder, kept for that purpose. If, at any time, the man should be rehired, the leaf is again inserted in the "mine register," and, if possible, the same "identification number" is given him, the date of reëmployment being marked on the leaf.

The identification numbers are given out in rotation, and are assigned to the outside men as well as those working inside, but the "pegging-in" board or check board is used only for the inside men. If a "company man," the new employee also is given a brass check with a number, called the "company number."

Remarks:

CHECKING SYSTEM

In this province, a law, commonly called the eight-hour law, is in force. This limits the hours of work underground to eight hours and makes it compulsory to keep a register showing the times of ascent and descent of each shift. It is essential, therefore, to have some good reliable checking system that will show at all times the number of men in the mine and will record at the completion of a shift the number of men, if any, left in the workings. A system of this kind is of great value, especially in the case of serious accidents, when there is so much confusion and when reliable information is so essential. The form of record in use at the Coleman mine is shown in Fig. 2.

The check board, on which is kept a record of the men at work, is made of 1-in. kiln-dried pine, free from all knots or blemishes and straight grained. The accompanying illustration, Fig. 3, shows a part of the board used at Coleman and is almost self-explanatory, but in order to make it as clear as possible a description may be given as follows:

The left side of the board is devoted to keeping track of the No. 2 Seam contract miners. The contracts are numbered from 1 to 60, and opposite each number

FIG. 2. THE "EIGHT HOUR" REGISTER

DATE	Time at Which Shift Commenced to be Admitted to Mine	Time at Which Shift Commenced to Return from Mine	NAME	Hours Worked in Excess of Time Fixed by Act	Cause of Time Being Worked in Excess of That Fixed by Act	REMARKS	SIGNATURE

are holes for 10 pegs, which amply provide for the men on each contract. Alongside the contract numbers on the board, room is left to tack a small piece of celluloid on which can be printed the location of each particular contract. When one working place is finished, the celluloid can be cleaned off easily and the new place marked on.

Above each line of holes, a light piece of cardboard, divided into ten parts, is slipped through three or four common staples. Each division corresponds to a hole on the board, and on this cardboard the men's names are written. If a man is shifted from one contract to another, this record can easily be changed.

On the lower left-hand side of the board (not shown in Fig. 3), the same arrangement is followed out for contract miners working in No. 4 seam, and the contract numbers here run from 101 to 160, inclusive. This arrangement is necessary because there are two seams being worked, No. 2 and No. 4.

On the right side of the board is kept a record of the company men, the No. 2 men on top and the No. 4 men below. Practically the same system is followed here as for the contract miners, except that the company men are divided into the various classes of inside labor, such as bratticemen, trappers, firebosses, transportation men, trackmen, chute loaders, timber packers, laborers and development men—the latter including all men employed on new work, such as driving rock tunnels, etc., and work chargeable to capital account.

Each hole on this side of the board is given a number (company number). The No. 2 men are all given numbers beginning with 2, and the No. 4 men, numbers beginning with 4. This gives ample room for expansion, 1000 numbers for each seam thus being available. A piece of cardboard, bearing the names of the men, is slipped through staples above the holes in the manner previously noted. The number on the board corresponds to the number on the company check, which is given to a man when he registers.

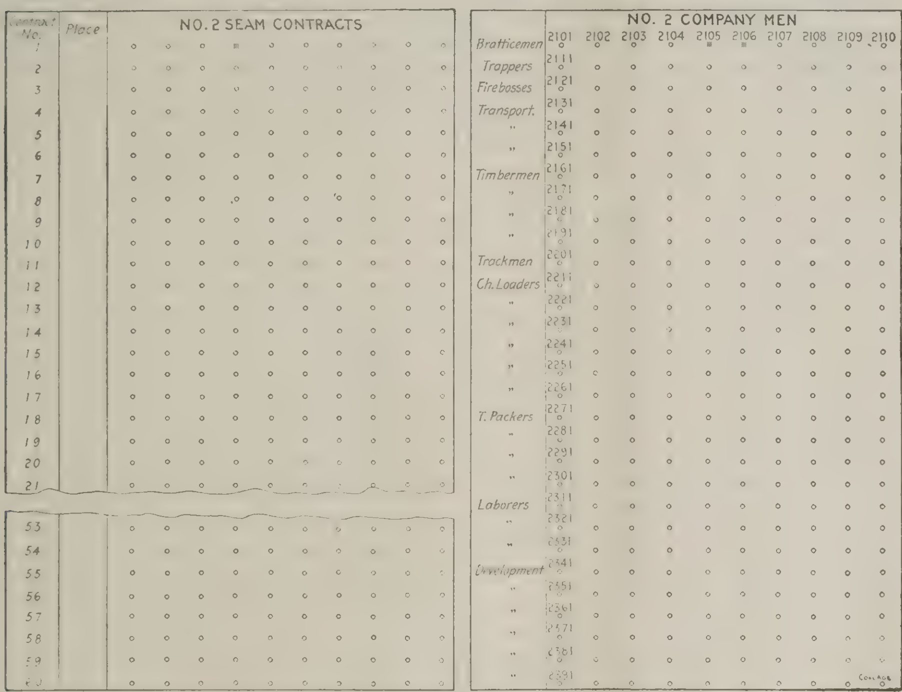

Fig. 3. Check Board for Operations in No. 2 Seam

Checking the Men In and Out

When a contract miner enters the mine, he calls his name and contract number and a peg is put in under his name. When he comes out, he calls out the same information and the peg is removed. A company man simply calls his number, as, for instance, 2262; otherwise the procedure is identical.

Some of the advantages of this checking board are as follows: When the shift has passed, going out, if any pegs are left in the check board, it becomes known immediately that someone is still in the mine, and the board tells who it is and where he was working. Similarly, when the shift is going on, the board at once shows the absentees and their working places, which can be filled from the "open links." The working time is transferred directly from the board to the books. All surface men who go into the mine temporarily to do repair work, have their names placed on the board and are

Boys Men

required to check in and out in the same way as underground men, so, as stated before, the board shows at all times the men actually below ground.

In addition to booking the time, a daily record is kept of each shift, showing the number of men employed. This is obtained by simply counting the pegs on the board after the shift has passed, and the result is entered on the form shown in Fig. 4. The classification of labor on this sheet is the same as on the board. Such a record is of immense value to the mine manager, as can be understood without further explanation.

Keeping Track of Several Shifts

When two shifts overlap, as in the case of one shift starting at 7 o'clock and another at 9 o'clock, a different style of peg is used for each shift. In this particular case it has been found necessary to use only two kinds of pegs. The common brattice nail, along with the ordinary 3-in. spike, cut off somewhat, serve the purpose well enough. The 3-in. spike, being a little brighter and slightly longer than the brattice nail, makes the distinction quite evident. For conditions more complicated, different colored pegs could be used.

A person standing centrally in front of the board can easily reach all parts of it, and the pegs can be worked quickly, as are the keys of an instrument, so that if all the men of a shift follow one another closely, the board can be cleared accurately in two minutes.

At this mine there are two checking-in stations, No. 1 and No. 2. No. 1 is the main station. Exactly the same system is followed at Station No. 2 as at No. 1, but the board is not quite so large, because the board at No. 1 includes the record for No. 2. After the men check in at No. 2, the result is telephoned to No. 1 and their pegs are also put in No. 1 board. At the end of the shift, No. 1 station is informed whether or not No. 2 is clear, so that the board at Station No. 1 covers the whole mine and shows at all times the total number of men below ground. This system has been found to be entirely satisfactory, and there is no reason why any number of stations could not be worked in the same way—each reporting to No. 1.

The Jamison Coke Plants, Greensburg

By R. Dawson Hall

These plants make only 72- and 96-hour coke. Ovens are now supplying waste gas to two boiler plants. Over 20 horsepower is supplied by each oven and no coal is fed to the boilers even on Mondays. The coke made by the waste-gas ovens is superior to the ordinary beehive coke, being free from black butts and a trifle lower in sulphur.

The subject of the utilization of the waste gas from coke ovens has been so much discussed and yet so little comparatively has arisen from the discussion that it is thought that the following article may be of value to those who still retain the old bee-hive oven methods. There is no question but that the waste-heat boiler has come to stay wherever coke is made in bee-hive ovens and the problem is now what is to be done with the excess heat after all the needs of the colliery as regards power production are provided.

Those who have studied the use of waste heat are convinced that the logic of the situation favors the installation of means to utilize it at least to a degree sufficient to meet the full demands of the colliery where the coke is made. The sale of excess power is a larger question. It is to be hoped that some means may be found enabling the operator to sell this power, which costs him nothing except a comparatively small initial outlay.

Jamison Plants

The Jamison Coal and Coke Co., John M. Jamison, president, and W. W. Jamison, vice-president, at their Greensburg operations, mine approximately 2,500,000 tons per annum. They also have large interests in West Virginia, but the matter of this article is confined to a consideration of three coke-oven plants of the following names, locations and equipments: No. 1 at Luxor with 401 ovens, No. 2 at Hannastown with 516 ovens and No. 4 at Crabtree with 492 ovens, a total of 1409 ovens. The coal mined is the Pittsburg and runs from 7 ft. 6 in. to 8 ft. thick in this section.

When the coal comes from the mines, all which passes through a 4-in. screen is shipped. The balance is washed after crushing and made into coke, the analyses of the materials at the various stages being as follows:

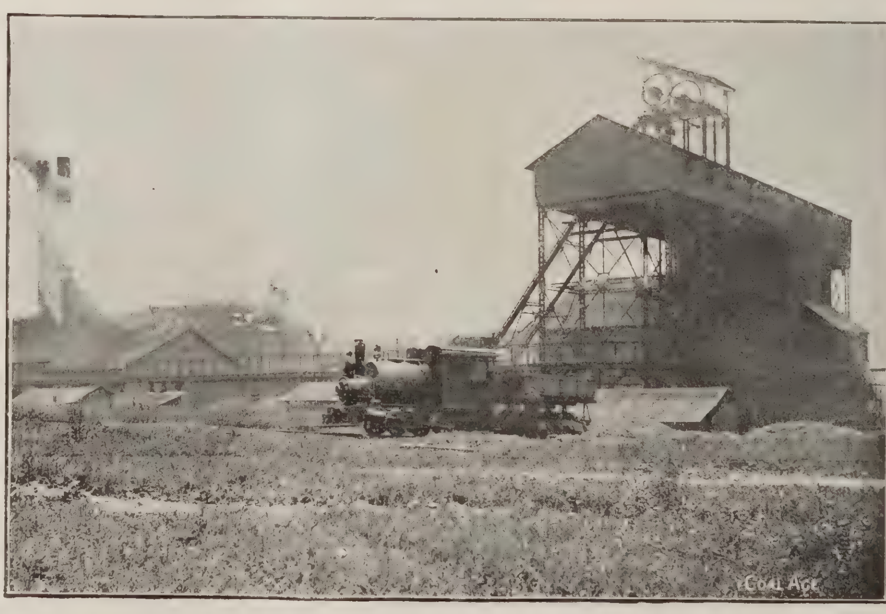
ANALYSES OF COAL AND COKE
JAMISON PLANTS

	Ash	Sulphur	Moisture	Volatile Matter	Fixed Carbon
Screened coal	7.45	1.28	0.70	32.95	58.90
Washer slack	10.00	1.40			
Washed coal	7.50	1.10			
Coke	9.80	0.88	0.16	1.00	89.04

It may be noted, though it is a trite observation, that the slack, which at these plants goes to the washer, is not as good as the coal which is shipped to market. This is always the case, the bulk of the impurities being found in the disintegrated coal.

The slack is washed in Stein-Boericke and Luhrig jigs and the cleansed product is discharged into one of two large tanks. These tanks at plant No. 2 are of iron, lined with brickwork, the joints being filled with cement. At the other plants they are of reinforced concrete. They are filled on alternate days. Elevators remove the slack from one tank at a time and empty it into bins for charging into larries.

By this means the washed coal is rendered comparatively dry before charging. This drying not only avoids an important waste of heat, but practically extends the coking period one hour and as it results in the heat of adjacent ovens not being



Jamison Mine No. 2 Hannastown, Penn.

A Row of Ovens at Jamison Mine No. 2

absorbed unduly by ovens newly charged, it provides for an oven temperature suitable for the manufacture of the strongest and densest coke. It is probable that some sulphur leaves the coal during the interval of storage, because the water drawn off is quite strongly impregnated with sulphuric acid. The pyrites can be entirely robbed of its sulphur by oxidation and solution, whereas the heat of the oven can only drive off 50 per cent. of it. Consequently it would seem that a leaching process, which is not carried far enough to destroy the coking power of the coal, should be advantageous. I have not seen any data on the subject, but it would appear to be a fertile field for investigation. The generalized symbol for pyrites is Fe_nS_{n+1} and that symbol still remains applicable after heating the mineral. The factor n, however, progressively becomes so great that it practically equals $n + 1$ and FeS_2, after being strongly heated, becomes FeS.

Foundry Coke

The Jamison plants aim to make nothing but foundry coke. Instead of charging each oven every alternate day except Sundays and drawing furnace coke four days in the week and foundry coke on Mondays and Tuesdays, each oven is charged but once in three days, and if Sunday intervenes the coal remains in the oven four days. So all the ovens are producing either 72- or 96-hour coke. Three grades are made, A, B and C, the first, A, is No. 1 foundry, B is No. 2 foundry and C is furnace coke. There is a large amount of the product sold on a guarantee that the sulphur content shall be less than 0.90 per cent.

The following are the input and output of 72- and 96-hour charges:

CHARGE AND OUTPUT OF COKE OVENS

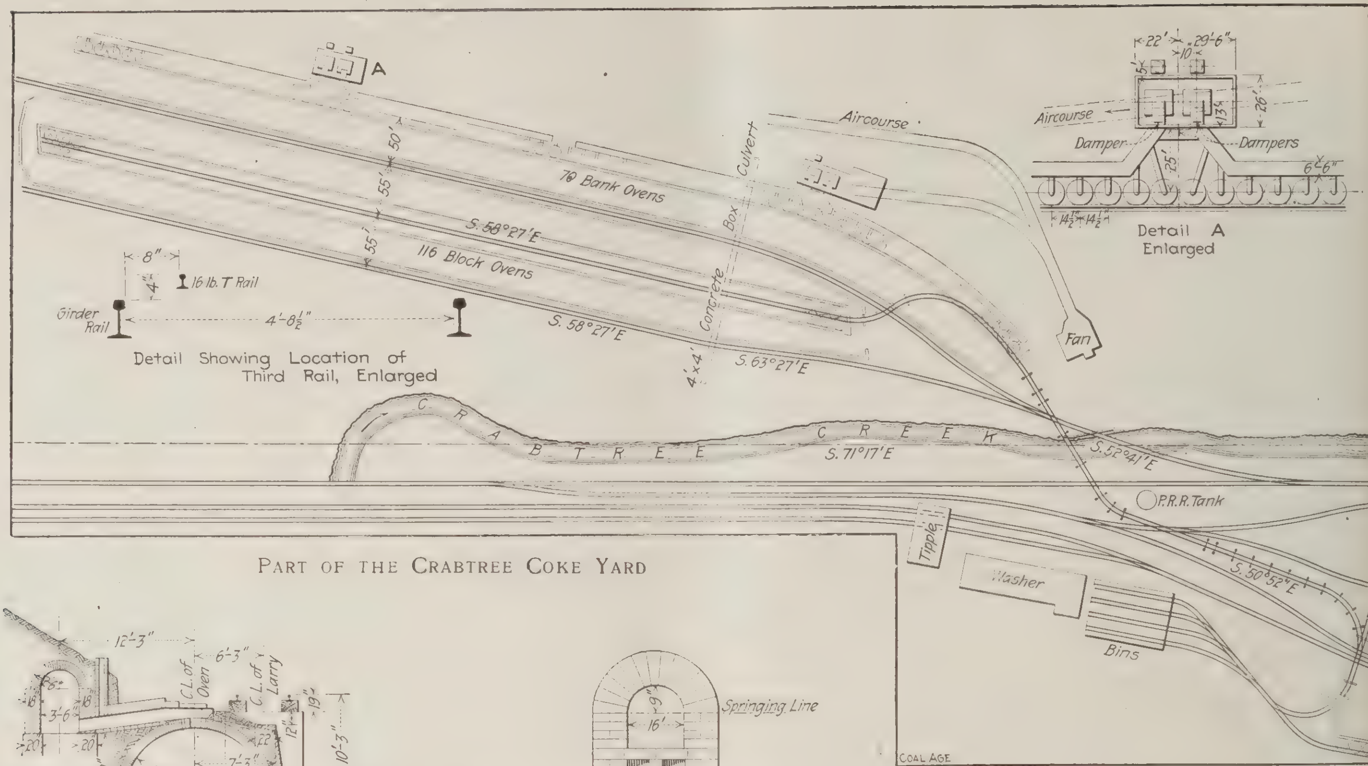
	72-hour Charge		
Material	Pounds	Per Cent. of Charge	Per Cent. of Output
Washed coal	15,680	100.00	132.09
Good foundry coke	9,528	60.76	80.27
Culls	1,706	10.88	14.37
Breeze	636	4.06	5.36
Total output	11,870	75.70	100.00

	96-hour Charge		
Material	Pounds	Per Cent. of Charge	Per Cent. of Output
Washed coal	17,655	100.00	136.42
Good foundry coke	10,330	58.51	79.82
Culls	2,044	11.58	15.79
Breeze	568	3.21	4.39
Total output	12,942	73.30	100.00

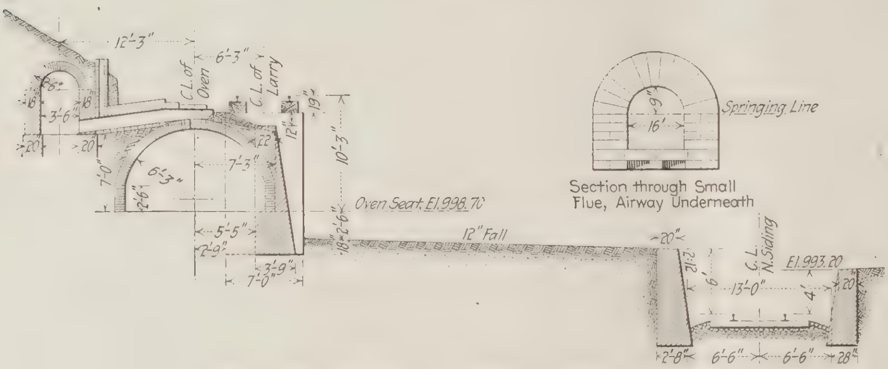
A 96-hour charge stands about 40 in. deep in the oven, and after coking it will be found shrunken to about 28 in. When coal is taken direct from the washer to the ovens, without the delay in the tanks, of which mention has been made, it is two hours before it begins to coke; but as a result of the opportunity the coal has to drain off, the time at the Jamison works is reduced to one hour. The door of the oven, which is only built about half way up to the soffit of the arched opening, is after this hour raised almost to the full height, the bricks being plastered with wet loam to exclude all air, except such as can enter above the coal. This prevents wasteful oxidation or burning of the charge.

The bricks forming the door are wet, to the full height of the slack bed, due to the dampness of the charge. As coking takes place, the bricks gradually dry, and when the coking reaches the oven floor, the entire door ceases to show evidences of moisture. This requires about 36 hours. Such coke, however, is light and weak, and the additional time given the process completes the driving off of the volatile matter and makes a heavier and stronger product. It may be noted that there is a deposit of carbon on those parts of the coke through which the rising gases escape, and the amount of this deposit varies from 3 to 5 per cent. The coke ovens at plant No. 1 are not at present in operation, and No. 2, though producing the best of coke, does not embody all the latest features of coke-making economy. Steam locomotives are used for hauling the larries to the oven and no use is made of the waste gases. It is the intention, however, to make the coke ovens supply the heat for operating this plant and the change will be made without delay because the test at No. 4 has shown that the waste-heat coke oven is a gilt-edged investment.

Waste Heat Ovens and Boiler House Plant No. 4



Part of the Crabtree Coke Yard



Part Cross Section of Oven, Tracks and Yards

Detail of Waste Heat Ovens Showing Flues

Each Oven Makes 22 HP., One Man Oversees 1600 HP.

At plant No. 4, seventy ovens are supplying all the heat needed for the operation of four 400-hp. boilers. In order to shorten the flues leading to these, there are two boiler houses set just back of the line of ovens, each house being connected with 35 ovens. By these arrangements a more even draft is secured for each oven, than if the boiler houses were combined and set at one end of the long line.

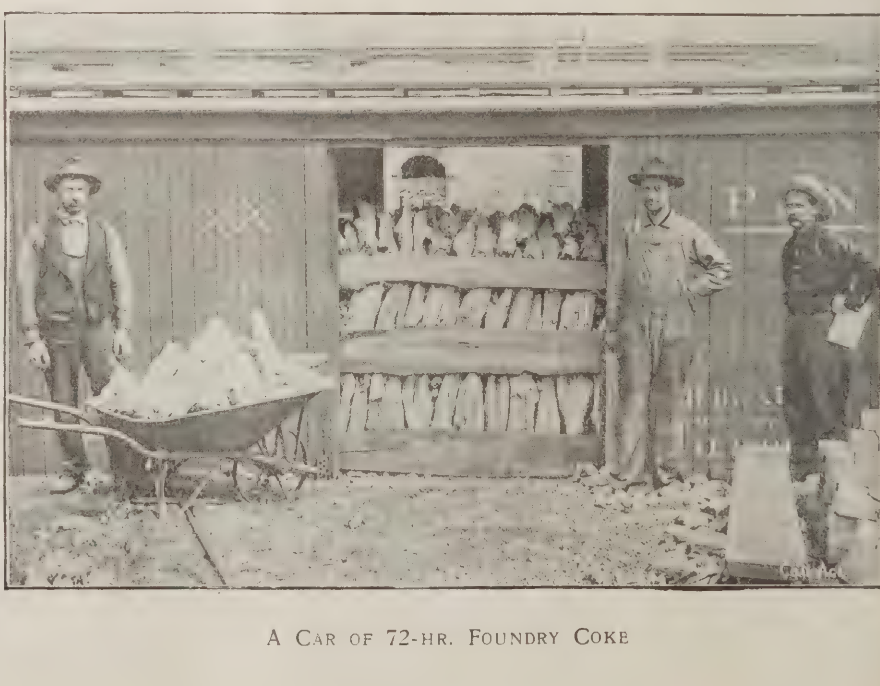
One man attends to all four boilers and watches the fan engine. He does not have much to occupy him physically or mentally and a high-priced man is not needed. Liberal allowances for interest, depreciation and repair leave a margin of about $20,000 over the coal firing. The cost of installation, including flues, boilers, steam lines, water lines complete, was approximately $350 per oven.

It will be seen that each oven provides about 22 hp. It is not thought that the continuous making of foundry coke changes the heat output in any material degree. It is true that the ovens are less frequently charged but, at the same time, larger charges are used and thus the conditions are not so unequal as might at first appear.

Any Oven Should Provide 20 HP.

An oven operating on the regular cycle, but of like diameter to those at the Jamison plants (12 ft. 6 in.), is charged every week with two chargings of about five tons each, and on Friday or Saturday with 6½ tons, a total of 16½ tons per week. It will be seen that the amount fed to the ovens at the Jamison plants with a two-charge system is 16⅔ tons. So that on the whole, there is no reason to believe that the three-charge system with its smaller charging loads will not give almost equivalent results. In fact it has been the experience of the H. C. Frick Coke Co., and the Ellsworth Coal Co., that 20 hp. is to be expected from a single coke oven.

The method of utilizing the waste gases has been developed by several experiments during the last few years. The heated gas is taken from the trunnel-head. This head can be covered by a large firebrick lid. When this is closed the gas passes through a conduit built on



A Car of 72-hr. Foundry Coke

a slightly descending grade toward the main flue. When first installed the small flues were covered by the slope of the bank of earth by which the main flue was protected, but it was found later to be a better plan to leave them uncovered as in the sectional elevation shown, because the intense heat did not then have as great an effect on their firebrick arches.

Closing off Boilers

The large brick flue at the back of the oven leads the gas away to the nearest boiler house. Should it be desirable to clean any boiler or to shut it off for repairs, a damper provides the means and a cross-flue between the flue to the right-hand boiler and that to the left permits the gases from one flue to be sidepassed from the boiler they normally heat to that which under ordinary conditions is heated by the adjacent stack of ovens.

Edward Soppitt

It is, of course, possible to overheat an oven, and this is not desirable, as the coke is thereby rendered brittle and valueless. But if the temperature be too low, the coke has black butts near the oven floor and is discolored in other places. As this half-coked coal and soot are undesirable, a sufficient heat to eliminate them and make them into a solid, shining body of coke is needed. Moreover, an intensely heated oven will eliminate somewhat more sulphur than one of lower temperature. But the present arrangement with a chimney about 130 ft. higher than the oven bed gives somewhat too much draft if not regulated, and reduction in height is proposed as remedy for this condition.

In conclusion, the ovens are giving excellent results, the coke made by them is better than that of ovens without provision for the use of the waste gases. The coke is brighter and harder and somewhat lower in sulphur. The success attained is evidenced by the fact that some of the ovens at plant No. 2 are to be made over. It is believed that the expense for maintenance where this system is installed will not be heavy. The main flue has stood two years without needing any repair.

It may be noted that the third-rail system of transmitting power is adopted and electric larries built by the Scottdale Foundry and Machine Co., are used to convey the coal from the washery bins, an ordinary 16-lb. rail, set with its upper surface 4 in. above the track rail being used for transmission purposes. The voltage is 250 volts. The electrical equipment was furnished by the Westinghouse Electric and Manufacturing Co.

The writer is indebted to Edward Soppitt, general superintendent Pennsylvania district; C. E. Cowan, chief engineer, and John McClarren, general foreman of the coke yards, for information and assistance in preparing the article.

Diamond Vale Disaster

The explosion which occurred at Merritt, B. C., was given a short notice in Coal Age in the issue following the unhappy event. The report of the coroner's jury being now at hand, a further statement seems timely. Merritt is situated in the Cariboo District of British Columbia, on the Nicola River, a branch of the Fraser, and is one of the stations of the Canadian Pacific Railway.

Report of Coroner's Jury

The conclusion reached by the jury was that the seven men who were killed "met their death by the explosion of gas combined with coal dust coming in contact with a naked light." This statement is easy to understand despite its ill expression. The jury finds that the management was guilty of gross negligence in not having provided efficient equipment and that the company showed a disposition to evade the requirements of the Coal Mines Regulation Act. .The inspector, Morgan, was also censured for not demanding a more careful compliance with the law. In addition to the seven men killed, two were injured, out of the 18 men working in the mine.

It appears that the development was new and was regarded more or less as a prospect rather than as a working mine. The equipment was such as suited an operation of little importance and one of which the future was in doubt. This was the excuse of Benjamin Browett, the superintendent, when taxed with the inadequacy of the plant. He stated that he did not think the mine was at such a state of development as to make it subject to the law and that he thought he could not be held to be amenable to its provisions without formal notification from the inspector.

Slow the Fan to Permit of Haulage

It was said, but denied by the engineer, that the fan could not be kept running when the haulage engine was working because the power provided was insufficient to actuate both at one and the same time.

The fireboss, Henry Grimes, one of the victims, was not a certificated man. He went into the mine at 6.45 a.m. and the men entered at 8. It was asserted that he had plenty of time to make an inspection of the limited area under operation The fireboss was in the habit of stationing himself where the men would pass him on entering and he would notify them if their places were in an unsafe condition. He did not write his report till he came out of the mine at dinner time. He seems to have been a well meaning man and several witnesses among the miners commented favorably on his efficiency.

Evidently the mine generated gas. Open lights were used but safety lamps were carried by some of the men. Some carried both, using the former for testing purposes when gas was suspected. One man was waiting to tell the superintendent of the presence of gas when the explosion occurred. It seems as if the fireboss was active enough in the discharge of his duties but did not have a clear comprehension of the dangers to be avoided in a gaseous mine, nor was he strict enough in controlling those who would carelessly brave them.

"Not an Explosion, Only an Inflammation"

James Ashworth, Fleet Robinson, the Dominion mineralogist and Chief Inspector Thomas Graham made a report stating that there was no explosion, but merely an inflammation of the gas followed by a burning of the coal dust. Mr. Ashworth testified that in his belief the temperature resulting from the combustion did not exceed 900 deg. F. He stated that in case of an explosion the temperature would have been 3000 deg. In support of his conclusion he brought samples of coal dust, caked but not burned, and the cap, which was worn by William Herd, one of the deceased, at the time of the accident. This was charred a little on the outside but the paper on the inside was unburned.

However, it must be questioned whether gas could ever have burned so generally through the mine without an explosion. In fact there was evidence given that sufficient force was developed to turn over a car, damage the return airway and "blow out the fan." Moreover, most of the surviving men heard the explosion, though all said the noise was faint.

As to deductions from temperatures, these are unsafe because the intensity of heat is not equal, especially when the exploded gases are small in quantity.

Accidents in Anthracite Coal Mines

By Frederick L. Hoffman*

Tabulations showing the number of persons killed and injured and the nature of the accidents occurring in each inspection district of the Pennsylvania anthracite region from 1906 to 1910. It is shown that a great difference exists between districts and that a general average does not give a true idea of any one section.

In order to understand fully the accident problem in coal mining, it is necessary to consider the bearing of particular causes in their relation to the number of persons employed. Separating at the commencement of such an inquiry, the inside from the outside employees, a marked contrast in accident liabilities can be shown. This result suggests the inadequacy of general fatality rates, since the proportions of inside and outside employees may vary substantially for different mining fields.

TABLE I. ACCIDENTS IN THE NORTHERN ANTHRACITE COAL FIELD OF PENNSYLVANIA, 1906–1910

Year	Employees	Fatal Accidents	Rate per 1000 Employe's	Non-fatal Accidents	Rate per 1000 Employees
Inside Accidents					
1906	67,852	290	4.27	587	8.65
1907	69,459	385	5.54	699	10.06
1908	73,347	366	4.99	605	8.25
1909	73,976	316	4.27	526	7.11
1910	72,993	337	4.62	505	6.92
Total.	357,627	1694	4.74	2922	8.17
Outside Accidents					
1906	24,148	49	2.03	107	4.43
1907	24,046	55	2.29	116	4.82
1908	23,889	49	2.05	109	4.56
1909	23,108	27	1.17	98	4.24
1910	22,523	30	1.33	74	3.29
Total.	117,714	210	1.78	504	4.28
All Accidents, Inside and Outside					
1906	92,009	339	3.68	694	7.54
1907	93,505	440	4.71	815	8.72
1908	97,236	415	4.27	711	7.34
1909	97,084	343	3.53	624	6.43
1910	95,516	367	3.84	579	6.53
Total.	475,341	1904	4.01	3426	7.21

In the northern anthracite coal fields of Pennsylvania, for illustration, the average proportion of inside employees is 75.2 per cent., and of outside employees 24.8 per cent., against 65.4 per cent. and 34.6 per cent., respectively, for the combined middle and southern fields. Obviously, the fatality rates, to be trustworthy, require to be corrected for this element of error, which may, more or less, impair the trustworthiness of all general fatality tables. Unfortunately, the number of inside and outside employees of many states is not separately stated, even though the accident returns may make the distinction, but of course, without the required numbers of employees under and above ground, the data are of no practical utility.

Looking over the many items in the various tables accompanying this article, it will be readily seen that the rate for accidental death and injuries is different in the northern fields from that in the two lower areas. Moreover, the accidents are different not only in number but also in nature—the character of the life hazard varying from field to field.

The most marked difference in the fatality rates, as calculated for various

causes, are in the accidents due to falls of coal and roof. The respective rates were 2.46 per 1000 of inside employees for the northern coal fields, against only 1.66 for the middle and southern fields. In none of the other causes are the differences of enough importance for record, except possibly explosions of gas or dust, the rate for which in the northern coal field was 0.38 per 1000, against 0.23 in the middle and southern coal fields.

The returns of non-fatal accidents, in table IV are of doubtful accuracy and completeness and are limited probably to the more serious injuries causing extended incapacity for work. The marked differences in the non-fatal accident rates between the northern field and the middle and southern coal areas, are probably due more to methods of reporting them than to actual differences in the true non-fatal accident liability of inside employees. It is suggestive, however, to find a marked difference in the non-fatal accident rate due to mine cars, which was 2.14 per 1000 for the northern coal fields and only 1.35 for the other two. In contrast, the non-fatal accident rate due to explosions of gas and dust was only 0.90 per 1000 in the northern, against 1.52 in the middle and southern coal fields.

Although the non-fatal accident returns are more or less untrustworthy, the data have some value if only to emphasize the fact that in all probability only the more severe accidents are at present reported. There can be no question of doubt that if a drastic workmen's compensation act were to be adopted by the State of Pennsylvania, and applied to the mining industry, the results would be the same as observed in England, namely, that the non-fatal accident rates would increase largely on account of the fact that complete reports would be made of every injury, however, trifling, which resulted from an accident incidental to mine work.

This comparison clearly emphasizes the local incidence of fatal and non-fatal accidents in anthracite coal mining, and the method is applicable to every coalfield of North America. For a full understanding of the underlying causes responsible for the occurrence of fatal and non-fatal accidents it is of the utmost importance that the correct incidence should be localized as much as possible and that attention should be directed to specific facts rather than to widely generalized conclusions.

The non-fatal accident rate in the northern anthracite coalfields is reported as 7.21 per 1000, the highest rate bèing for the eighth district, where it was 10.85 per 1000, and the lowest for the second district, where it was 4.69 per 1000. The highest and lowest non-fatal acci-

dent rates do not coincide by districts with the corresponding fatal accident rates, which were highest in the seventh district and lowest in the fifth.

The average non-fatal accident rate for the middle and southern coalfields was 6.45 per 1000, the rate having been highest in the eighteenth district, or 10.21 per 1000, and lowest in the fifteenth district, or 2.62 per 1000. The highest non-fatal accident rate coincides with the highest fatal accident rate in the middle and southern anthracite coal fields, but there is no complete conformity in the rates, which, of course, may be due to local conditions rather than to defects in the returns.

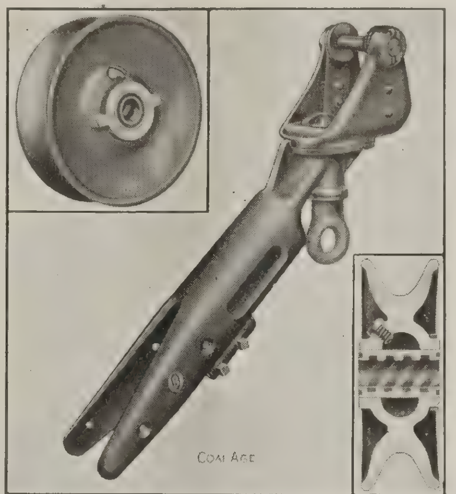
Mine Trolley Harp and Wheel

Probably no single piece of machinery in use around the mines is liable to more hard knocks and general abuse than the trolley of the average mine locomotive. With well known frequency its wheel leaves the wire and bangs up against the roof for a distance, catching, perhaps, on timbers, beams and other obstacles. No little ingenuity has been displayed by various manufacturers in designing trolley poles, harps, etc., in an effort to minimize mishaps of the nature indicated and one of the most recent designs of harp and wheel is that of the Ohio Brass Co., shown in the accompanying illustration.



TROLLEY HARP AND WHEEL

A special feature of the harp is the provision made for rotating it by hand, thus enabling the motorman to guide it easily through frogs and over particularly uneven places in the trolley. The pivot bolt, fastened to the harp casting, passes through the pole-end casting and is provided at its lower end with an eye which rotates with the harp. A stick or strap, attached to this eye, enables the operator to control the harp at all times.

In addition to the feature of manual operation, the harp is designed to work automatically; the center of the wheel axle is set back from the pivot point so that a trailing action is imparted to the wheel, causing it readily to follow irregularities in the trolley wire and take sharp curves without pulling from the wire.

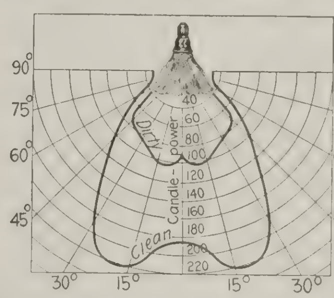
A rib on the top of the pole-end casting prevents the harp from catching on overhead I-beams in case the wheel leaves the wire. It is made either entirely of malleable iron, Sherardized, or with bronze harp casting and malleable iron pole-end, and will take all standard 4-in. mine trolley wheels with $\frac{1}{2}$x$1\frac{1}{2}$-in. hubs.

The wheel is designed to give maximum wear, having heavy flanges which will resist bending and a heavy section of metal at the bottom of the groove where the wear is greatest. Lubrication is provided for by an oil reservoir, in addition to a Bound Brook type bushing, with graphite inserted in grooves in the special bearing metal of which it is made. The bushings are $1\frac{1}{2}$ in. long and $\frac{1}{2}$-in. bore and the wheel will fit any standard harp.

Lamp Efficiency

Every mining man is familiar with the dirty, greasy and neglected incandescent lamps commonly found in some obscure part of breakers, fan-houses or mines. To those who are responsible for this condition, the following excerpt from an article on "Upkeep of Shop Lighting Systems," in the *American Machinist*, will no doubt prove a revelation:

The serious loss of light when globes and reflectors are allowed to go for long periods without cleaning, is shown in the accompanying figure. This set of curves resulted from a test on a glass



CURVES SHOWING LOSSES DUE TO UNCLEAN LAMPS

reflector (commonly called a shade) used with a tungsten lamp. The one curve shows the value of the light given by the lamp at different angles when the lamp and reflector are clean, while the smaller curve shows the enormous reduction of light after the lamp and reflector had been in service for about four months without being cleaned.

In this particular case, which is a typical one, the loss of light at the end of the four months amounted to nearly 50 per cent. The cost of electrical energy in the shop where this test was made was such that the loss of light during the four months amounted to about 12c., while the total cost of taking down, washing and replacing this reflector amounted to about 3c., so that the economy of a fairly frequent attention to the cleaning of such reflectors, even if the improved condition of the light in itself be ignored, is at once apparent.

When handling coal in a breaker great care should be taken to reduce breakage to a minimum. Sloping chutes should be curved to prevent the coal going too fast; all corners should be rounded so there are no sudden drops or sharp angles; perpendicular chutes or shafts should be constructed shelf-like to deflect the coal from side to side, thus overcoming the straight drop which is a great source of breakage.

The Consolidated Fuel Co. of Utah

By Benedict Shubart*

A description of a characteristic mountain coal operation and some of the difficulties encountered. A gravity plane, nearly two miles long, is in use, the grades on which are so light that the data given form a valuable addition to the technical literature on this subject. The tipple is equipped with a gravity rotating dump and has a capacity of 3000 tons per 8-hour day.

*Boston Building, Denver, Colo.

Up to three or four years ago, one of the least known coal fields in the United States was that lying south of the town of Price, Carbon County, Utah. For many years past, the Utah Fuel Co. has been operating on the northern edge of this field, at Sunnyside, and on the western edge, at Castle Gate, Winter Quarters and Clear Creek. The southern body of the coal, however, lies in a very rugged country, and engineering difficulties connected with the railroad construction, deterred investigators from attempting the opening up of this field. In fact, the operators first occupying the field claimed that all the available coal was controlled by them, and that no new mines could be opened up.

Preliminary Work

Some five or six years ago, Arthur A. Sweet, of Salt Lake, a promoter of great ingenuity and daring, entered the field, bought up several thousand acres of coal land in Miller Creek Cañon, and started the construction of what is now the Southern Utah R.R. Encountering many unforeseen difficulties, both in engineering and financing, he surrendered the managership of the company to his brother, Fred A. Sweet, also of Salt Lake, who had just successfully completed the construction of the American Falls Canal, in Idaho. Under his guidance the railroad was pushed through, and the development of the Consolidated Fuel Co.'s Hiawatha mine was carried through to its present state of completeness.

By careful location, the railroad, 16 miles in length, from Price to Hiawatha, was built, with a maximum grade of 4 per cent., and this only for a short stretch. The railroad, having no grade against the loaded trains, is capable of handling a large tonnage.

Geologically, the seam now being worked is a continuation of the Sunnyside seam. It lies almost level and varies in thickness from 17 ft. to 35 ft. The coal is quite clean, has a fine, glossy fracture, and stands handling better than any Western coal I have ever examined. The coal east of the circle defined by Sunnyside, Castle Gate, Clear Creek, Hiawatha and Mohrland has been eroded. The southern boundary has not been thoroughly determined, but the field is so extensive that its exhaustion is a matter of many years.

The next five years will probably see immense developments in this field. Railroad lines are being surveyed to give an outlet to southern Utah, and it is decidedly probable that one of the large systems will swing its line south, to intercept the field.

Fig. 1. Some Heavy Work on the Gravity Plane

Fig. 2. General View of the Stone Power House

The Gravity Plane

While not the first independent operator on the Sunnyside seam, the Consolidated Fuel Co. is the first to open up the southern portion. The tipple is situated at the southern end of the railroad and the mine is two miles farther up Miller Creek, and is connected with the tipple by means of a gravity plane.

The flatness of this plane makes it worthy of consideration. With a total length of 10,400 ft., starting with a 9 per cent. grade and ending up with a 4 per cent., it has been found thoroughly practicable to operate and land the trip without difficulty upon the tipple. Of course, in order to secure these results on such flat grades, it was necessary to construct a track of the highest quality, to use very efficient and frictionless sheaves, and pit cars with very low rolling friction. A special design of roller-bearing wheels, made by the Watt Mining Car Wheel Co., is used, and the first design tried was found to require a considerable amount of correction. Small troubles cropped out, and it was only after a great deal of patient work that the company evolved a satisfactory and successful roller bearing. The rope rollers are of manganese steel, very light, and mounted on Hyatt roller bearings. The gravity sheaves were specially designed by the Denver Engineering Works Co. The magnificent roadbed of this gravity plane is shown in the accompanying halftone, Fig. 1. Running through a cañon as

rugged as can well be imagined, this tramway was completed with only two curves.

System of Mining and Haulage

As the seam is intercepted by the cañon, two mines have been opened up, the No. 1 at the left and the No. 2 at the right, as will be seen in Fig. 3, which shows the head of the incline with the hoist house and the transformer house.

The mines were originally opened up on the double-entry system, but are now being changed to a four-entry system. The coal is mined by the room-and-pillar system, with pillars about 55 ft. thick, and rooms about 25 ft. wide. A bench of about 9 ft. of coal is taken down first, and the balance of the roof coal, together with the pillars, will be brought back later when the rooms on the entry are finished.

The ventilation is obtained by a 7½-ft. Stevens fan, belt driven by a Ridgway variable-speed motor; the variable speed gives great flexibility to the air supply. A 6-ft. Jeffrey propeller fan is used to assist until the two mines are connected.

The entire haulage in the mine is done by electric motors, 6-ton Goodman being used for gathering the coal, and 10-ton

Fig. 3. The Top of the Gravity Plane

Goodman locomotives being used for the main haulage. The trips are delivered by the locomotives to the head of the incline, from which point they are handled by means of auxiliary hoists and the main gravity sheave.

All machinery is, as far as possible, electrically operated. In the power plant, shown in Fig. 2, are two 200-kv.-a., 220-volt, three-phase, 60-cycle, Ridgway alternators, direct-connected to Ridgway engines. These furnish the power for the entire mine. All the tipple apparatus is operated by means of three-phase, General Electric motors. In the hoist house, at the head of the incline, are two 200-hp., motor-generator sets, which furnish 250-volt current for the mine. These were furnished by the General Electric Co. and the Ridgway Dynamo & Engine Company.

The Tipple

The tipple, which was designed by the Link-Belt Co., presents a number of interesting features. Instead of using the old style crossover dump, a gravity rotating dump is used. The coal is discharged into a 20-ton hopper, from which it is automatically fed in an even stream on to the shaking screen. The results obtained with this feeder are so good that when running at the rate of 3000 tons per day, practically all the under size is taken out on the first 6 ft. of the screen. The slack is rescreened in a revolving screen, so no dust is shipped.

In order to prevent undue breaking of coal, a special apron is used for the lump screen. It takes the form of an adjustable, shaking chute, which is practically a continuation of the shaker screen. The delivery end can be raised, lowered or extended, so that open cars or box cars can be loaded with a minimum drop of the coal. This is necessary, due to the mixed character of the cars obtainable. The railroad furnishes anything from a 30,000-lb. to a 100,000-lb. gondola car, 30,000-lb. box cars to automobile cars, and it is often necessary to load hopper-bottom cars with sides as high as 10 ft. 6 in. above the rail.

The mine has now been in operation for 18 months. Its daily production is in excess of 1800 tons, and with the equipment now on hand, 3000 tons per 8-hour day can easily be handled. It is interesting to note that over the two-mile incline, in spite of the flat grade, coal has been repeatedly run for several hours at a time at a rate in excess of 4000 tons in eight hours.

Report on the Landslide at Frank, Alberta

On Apr. 29, 1903, a landslide occurred at Frank, Alberta, causing the loss of 70 lives in the town and the destruction of much property, including 7000 ft. of the Crows Nest Ry. The slide occurred on the north side of Turtle Mountain, which is due south of the town. As it appeared quite possible for further sliding to take place, which might not only destroy the town, but shut off the coal mines west of Frank and perhaps permanently close the Crows Nest pass, a commission was appointed by the Department of Mines, of Canada, to make an investigation. The report[1] of the commission, which consisted of Reginald A. Daly, W. G. Miller and George S. Rice, has recently been published and recommends the abandonment of the Frank townsite.

The geological profile of Turtle Mountain shows that the foot on the northern side is made up of beds of sandstone interbedded in shale. The beds dip toward the west at a steep angle. These beds are bounded on the north by a thrust plane dipping westward at an angle of about 50° and which is the plane of contact of the shale-sandstone beds with the limestone that forms the major portion of the upper part of the mountain. The limestone dips to the west at an angle of about 50° and lies unconformably on the shale. A short distance above the thrust plane the limestone beds are contorted in what are known as the contorted zones. The limestone is jointed, the joints running at right angles to the dip and continuing to the thrust plane.

Two coal mines are operated along the foot or east base of Turtle Mountain. The seam is nearly vertical and is in the shale series. Both mines are the property of the Canadian Coal Consolidated, Ltd., and formerly belonged to the Canadian-American Coal & Coke Co. The strike of the seam is north and nearly parallel to the long axis of Turtle Mountain. Mining was started in 1901 and prior to Apr. 29, 1903, the walls of part of the worked out portion of the southern end of the seam had caved. The joints in the limestone appear from the profiles prepared by the commission, to dip directly toward, but not to continue as far as, the main coal seam. The slide seems to have taken place in a direction approximately parallel to these joints.

The commission regards the slide as having been caused by natural conditions and by the mining operations in the coal seam. Excepting at the places known as the North Peak block and South Peak block and the fissured ground between them, the commission is not of the opinion that the danger of more heavy slides into the Frank Valley is imminent, but states that it is impossible to deny the existence of danger in certain places. The course of future slides would probably be in the already mined and now uninhabited area covered by the 1903 slide. It has designated a certain area of the coal seam as lying within a zone of danger from further landslides, and on account of the unstable condition from natural causes, has recommended the abandonment of the townsite of Frank whether the coal seam is worked in the danger zone or not.

Dispatches from Frank on Mar. 30 state that serious slides are taking place. Much alarm is being felt in the town and many people are reported to be moving out of the danger zone.

Note—From the "Engineering and Mining Journal."

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Anthracite Coal Freights

The following abstract is made from a series of editorials on the anthracite freight situation, appearing in the *Scranton Times,* of recent date:

It is difficult to conceive of a more desirable class of freight than anthracite coal as it comes to the railroads which center in this region. General freight is delivered to the railroads in boxes and bales, largely in less than carload lots. If it does not constitute a complete carload, it must usually be handled by the railroad at both termini. Much of it is perishable or fragile and subject to damage by accident or wreck. The average carload of freight weighs only 22 tons.

Anthracite coal, on the contrary, comes to the railroads, not in part or full carloads, but in sufficient quantities to make up the burden of a full train. The coal is loaded and unloaded at no charge to the railroad. It requires no station attention. It is neither perishable nor fragile. Even if there is a wreck and the cars are reduced to kindling wood, the maximum loss on the coal is the labor of shoveling it into another car. The average carload weighs about 40 tons.

And yet this easily and cheaply handled commodity, originating in such quantities as to form the major portion of the traffic of, at least, five railroads, the Lackawanna, the Reading, the Delaware & Hudson, the Central Railroad of New Jersey and the Lehigh Valley, suffers the imposition of a high rate, if not the highest rate charged for any commodity.

According to the reports we have, the most extortionate freights on anthracite coal are charged by the Reading railroad, which imposes a tariff of $1.70 a ton on prepared coal from Pottsville to Philadelphia, a distance of 93 miles, or 1.83c. per ton-mile, while some of the roads of this country carry bituminous coal at one-fifth of that ton rate. We are disposed, however, to tell of the conditions of anthracite coal transportation between the Lackawanna Valley and New York, because we have at hand a recent publication giving accurate figures on the subject. In large part they are from the freight schedules of the railroads themselves.

From this we learn that the rates for transporting coal from Scranton to Hoboken are:

Coal Sizes	Rate	F.o.b.
Prepared coal	$1.58	Hoboken
Pea coal	1.43	Hoboken
Buckwheat	1.28	Hoboken
Smaller sizes	1.35	Hoboken
Lackawanna average on smaller sizes	1.13	Vessel

The operators tell us that 60 per cent. of the coal mined is of prepared sizes and 40 per cent. steam sizes. The rate on prepared sizes, Scranton to Hoboken, is 1.089c. per ton-mile. It is shrewdly surmised that the percentage of prepared sizes is greater. But taking the word of the railroad men for it, the average tariff of anthracite coal per ton-mile is 0.837c., while the average tariff on all other merchandise is 0.696c. The cheapest and most easily handled freight is, therefore, rated 25 per cent. or more above the costlier freight, which requires greater care and attention.

The relative earnings of a trainload of coal and a trainload of general freight have been estimated as follows, figuring a $1.50 rate for prepared coal and $1.30 for smaller sizes. The load of a coal train is 1670.7 tons, and of a general freight train 504.44 tons, which includes coal loadings of 40.8 tons per car, as compared with an average loading of 22 tons. The haul is 145 miles.

60 per cent. of 1670.7 tons = 1002.42
40 per cent. of same = 668.28

Hence for a coal train:

1002.42 tons @ $1.50 per ton = $1,503.63
668.28 tons @ $1.30 per ton = 868.76

Total earned per train of coal $2,372.39

For a general freight train:

504.44 tons hauled 145 miles @ $0.00696 per ton-mile = $509.08
Coal earnings per train load exceed merchandise earnings $1.863.31

It will thus be seen that the Lackawanna company earns over four times as much on a train of coal from Scranton to Hoboken as on a train of general freight. And the cost of handling is less.

But the discrimination is more markedly shown when comparing the charges for carrying coal and other commodities between Scranton and nearby towns.

All small towns suffer from discriminatory rates, as may be noted from the instances cited above. The most flagrant instance, however, is Montrose, only 49 miles away from Scranton, which pays a freight rate of $1.65 a ton on anthracite, or 7c. more than Hoboken, which is 145 miles away. It may be noted here that no independent operator may sell at points along the line. He consequently does not profit in those high prices, being given 65 per cent. of the tidewater price as his sole compensation.

RELATIVE FREIGHTS

Freight	From	To	Distance, Miles	Rate
Prepared coal	Scranton	Moscow	12	$1.15
Sand	Moscow	Scranton	12	0.40
Prepared coal	Scranton	Nicholson		1.50
Wall stone	Nicholson	Scranton		0.40
Prepared coal	Taylor	La Plume	16	1.25
Manure	Taylor	La Plume	16	0.56

It is quite generally conceded, except by anthracite railroad officials, that the work entailed in the hauling of anthracite coal is about as great as in performing the same service with regard to bituminous coal. But the railroads hauling the latter exact a much lower tariff, as will be seen by the table at the foot of this page.

One has only to compare the rate per ton-mile in this table with the rate on anthracite coal to appreciate the wide disparity between the two.

We do not even have to go to the rates on bituminous coal to prove the discrimination which the coal roads are enabled to impose upon anthracite between the mines and tidewater, by reason of their control of the business. It was only recently that the Pennsylvania R.R. had a rate of 0.520c. per ton-mile on prepared coal from the heart of the anthracite coal regions to Hoboken, against the Lackawanna's rate, 1.089c. per ton-mile for a similar service. When anthracite coal goes beyond the limits of the railroads which produce it, it loses its preferential rate, foregoes the fancy prices and is car-

BITUMINOUS COAL RATES

Region	Railroad	Destination	Distance	Rate	Cents per Ton-mile
Myersdale	B. & O.	Baltimore	215.0	$1.18	0.549
Myersdale	B. & O.	Philadelphia	310.8	1.25	0.402
Myersdale	B. & O.	St. George	390.6	1.55	0.396
Pocahontas	N. & W.	Norfolk	377.0	1.40	0.371
Thurmond-New River	C. & O.	Newport News	418.0	1.40	0.335
Handley-Kanawha	C. & O.	Newport News	457.0	1.50	0.328
Marrowbone-Kentucky	C. & O.	Newport News	673.0	1.70	0.253
Beach Creek	N. Y., C., P. & R.	Port Reading	308.0	1.55	0.503
Beach Creek	N. Y., C., P. & R.	Philadelphia	229.0	1.25	0.546
Clearfield	Pennsylvania	Baltimore	242.2	1.18	0.487
Clearfield	Pennsylvania	South Amboy	322.5	1.55	0.481
Clearfield	Pennsylvania	Philadelphia	262.2	1.25	0.477

ried at a rate quite as low as bituminous coal. This is proved by the following table, showing rates from Buffalo westward:

RATES BEYOND FROM BUFFALO WESTWARD

To	Distance	Rate	Cents per Ton-mile
Louisville	516	$2.10	0.406
Cincinnati	446	1.50	0.336
Cleveland	183	0.85	0.464
Indianapolis	466	1.60	0.343
Terre Haute	593	2.00	0.337
Ft. Wayne	403	1.50	0.372
Logansport	478	1.75	0.366
Peoria	650	2.00	0.307
Detroit	151	1.00	0.662
Toledo	296	1.00	0.337

It has been truly said that there has never been an increase of wages by which the coal-carrying companies do not profit. The passing along to the consumer of the cost of a 10 per cent. advance in wages will add to the public coal bill about $25,000,000 a year, of which about $15,000,000 will go to the miners and $10,000,000 to the big corporations, to swell present satisfactory gains, if the present system continues to prevail.

The statements which follow show not only how prosperity has accrued to the anthracite coal roads since 1899, but how this prosperity has not been duplicated in other Eastern roads not participating in such traffic.

STOCK PRICES OF EASTERN RAILROADS

ANTHRACITE ROADS

	Market Value 1899	Div. 1899	Market Value 1912	Div. 1912
Delaware, Lackawanna & Western	194	7%	560	20%
Delaware & Hudson	125	7%	175	9%
Lehigh Valley	30	0%	186	10%
Reading	25	0%	164	6%
Central of New Jersey	126	4%	357	12%
Lehigh Coal & Navigation	91	4%	180	8%

OTHER RAILROADS

	Value 1899	Div. 1899	Value 1912	Div. 1912
Pennsylvania	142	6 %	123	6 %
New York Central	145	5 %	110	5 %
N. Y., N. H. & H.	222	8 %	136	8 %
Boston & Maine	215	6¼%	100½	5 %
Baltimore & Ohio	85	2 %	106⅞	6 %
Boston & Albany	282	8¾%	220	8¾%

It will be readily admitted that the railroads above mentioned are standard roads, operating in the same part of the country as the coal roads, and most of them touching more and larger towns with better chances to get more general freight and passenger traffic than the coal roads. Yet with a single exception the quotations for shares are very much lower in 1912 than they were in 1899, while the coal shares have made a marvellous increase. The one exception in which the quotation of shares of the other roads is greater than in 1899 is the Baltimore & Ohio. Its prosperity may be attributed to the fact that in the year 1903, the Baltimore & Ohio purchased more than $30,000,000 of the stock of the Reading R.R., when it ranged in price from 33 to 50, and has ever since been enjoying a return approximating 18 per cent. on its cash investment. So that even this showing of prosperity comes from anthracite coal.

Perhaps a table showing the value of these great properties in 1899, and their value in 1912, as shown by the stock quotations, together with the increase between these two years, will more impressively bring to the average reader an idea of the magnificent gains that have come to those fortunate owners of anthracite coal and the railroads which transport it.

It will be seen that, though, during the last 12 years there have been mined from the lands of these companies some 700,000,000 tons of coal, which is gone forever, and on which the corporations have their profits, the aggregate value has increased more than threefold. The Lackawanna R.R. is looked upon as a phenomenon, but it has increased in value only a little more than threefold, while the Reading has increased sixfold and the Lehigh Valley ninefold. The Central Railroad of New Jersey shows almost a threefold increase. The only new money put into any of these corporations is $20,000,000 into the Lehigh Valley and something over $2,000,000 into the Lehigh Coal & Navigation Company.

INCREASE IN VALUE OF RAILROAD PROPERTIES

Railroads	Value 1899	Value 1912	Increase
Delaware, Lackawanna & Western	$ 50,828,000	$169,551,200	$118,723,200
Delaware & Hudson	53,000,000	74,200,000	21,200,000
Lehigh Valley	12,000,000	112,720,880	100,720,880
Reading	35,000,000	229,600,000	194,600,000
Central of New Jersey	34,569,363	97,749,376	63,180,013
Lehigh Coal & Navigation	17,290,000	47,804,210	30,514,210
Totals	$202,687,363	$731,625,666	$528,938,303

The amount of dividends paid by these corporations during the 12 years from 1899 to 1912 is also a matter of interest in connection with this subject. The cash dividends only are shown in the following table:

DIVIDENDS DECLARED, 1899 TO 1912

Railroads	Per Cent.	Total Dividends
Delaware, Lackawanna & Western	213	$57,500,500
Central Railroad of New Jersey	100	27,436,800
Delaware & Hudson	92	39,008,000
Lehigh Valley	53	23,450,473
Reading	31½	44,100,000
Lehigh Coal & Navigation	72½	13,775,000
Total		$205,270,773

This does not include the stock dividend of 15 per cent. declared by the Lackawanna in 1909, nor the stock dividend by the same company in 1911 of 35 per cent. in stock of the Lackawanna Railroad of New Jersey, nor of the recently authorized issue of $12,000,000 additional stock which will probably go out as a stock dividend. It does not include the $2,000,000 of stock of the Lehigh Coal & Navigation Co. issued at par, nor the 15 per cent. scrip dividend of the same company convertible into stock. Nor does it include the valuable right to stockholders of the Lackawanna and the Lehigh Valley to subscribe at par for $6,000,000 stock in the respective coal companies, worth more than $200 a share, and yielding 10 per cent. dividends. With these included, the total would be considerably swelled.

Electricity in British Mining

In a paper on the use of electric power in the working of coal mines, read before the Manchester (England) Geological and Mining Society, Charles D. Taite said that the aggregate horsepower supplied to collieries in Lancashire by the Lancashire Electric Power Co. is at present about 3000, and this will shortly be increased by work in hand to about 4000. For some reason Lancashire has been slower to adopt electrical methods than other colliery districts. To the mines around Newcastle three power companies are supplying electrical energy at the rate of over 55,000,000 units per annum. In South Wales 12,500 hp. is being taken from the power company's mains, and a further 3500 hp. is contracted for. In the Clyde Valley district about 8500 hp. is either connected up or arranged for, while in Yorkshire the present connections deliver 4000 hp., with an additional 2000 hp. contracted for. Among other machinery using this energy are three electric hoists and three more are to be installed. Possibly the greater age of the shafts has something to do with the backward condition of Lancashire collieries electrically, compared with other British mine installations, but where coal is most difficult to extract the most modern methods are essential in order that the costs may be kept at the lowest possible figure.

The temperature of maximum weakness in a burning briquet is located between the melting point of the binder and the caking of the coal. For use with coals that cake at a high temperature binders must also have a high temperature melting point if they are to give good results when burning. Non-caking coals must be mated with non-melting binders. Starch gives the best burning results with such coals, but it is not waterproof. Soluble binders mean soluble briquets.

Shooting off the solid in bituminous mines is a dangerous and wasteful proceeding; dangerous, in that it is productive of windy or blowout shots which often cause dust explosions, and wasteful because it greatly increases the slack and fine coal, which is useless except where it can be used for coking purposes.

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

Famed as the home of Joe Cannon, bounded on the north by Lake Michigan and largely underlaid with 6 ft. of fairly decent commercial coal, is the great State of Illinois. Forty per cent. of the entire population staked out their homes on the lake front in a large community called Chicago, which latter town was created solely to supply Marshall Field with a dry-goods market and to furnish consumers of coal for Francis Peabody's City Fuel Co.

More than 800 Illinois coal mines have been opened by some 250 operating companies, which corporations are conducted in the interest of John Walker and 70,099 other miners who have contracted to relieve the owners of all responsibilities in the way of management of the properties; only requiring that the operators make good all working deficits, and be liable in case of accidents due to negligence on the part of an employee.

Out in this broad, flat, Middle West country, it originally cost about as much to open a coal mine as it did to start a corner grocery, and nearly as many people devoted their money and attention to mining as to selling canned goods and fresh vegetables. All the Coal Barons could remember how once upon a time a certain fellow made money mining coal in Illinois, and everyone labored on in the belief that the golden era would return.

Even the miners caught the fever, and four or five dozen coöperative coal companies were formed to develop that field lying across the river from St. Louis. However, when the supposedly huge profits that had been flowing into the coffers of the individual owners were divided up among the "producers of the wealth," there wasn't enough *to* go around, and failures came with greater regularity than dividends. But hope dies hard, and always there were those who were willing to repair the wreck and benevolently carry the work forward.

It is from great ruins that noble structures rise, and before many years have passed the coal industry in Illinois will be placed on a sane and satisfactory basis, and owner, miner and consumer will profit thereby. One of the men who will help bring about the new order of things is C. M. Moderwell, of Chicago, president of the United Coal Mining Co., and a man of force and vigor.

Mr. Moderwell is a native son of Illinois, having been born in Geneseo in 1868. His early training was secured

C. M. MODERWELL

in the high school of his home town. Following this preliminary education, he went to Wooster, Ohio, where he finished a general course in the University of Wooster, a Presbyterian school.

Having completed his theoretical training, Mr. Moderwell secured employment in Chicago, working for a railway association and devoting his attention and time to the Bureau of Joint Rate Inspection. In 1892 "C. M." became connected with the coal business, serving as a clerk in the office of the Montana Coal & Coke Co., a West Virginia concern controlled by the Watsons of the latter state. Three years later he was appointed Western sales agent for the West Virginia company, and served in this capacity until, in 1902, he entered business for himself, forming the National Coal & Coke Co., a corporation designed principally to do a jobbing business.

In 1905, when H. B. and W. P. Utley, partners in the business, retired from the firm, Mr. Moderwell formed the C. M. Moderwell Co., still doing a jobbing business. This same year he obtained options on a considerable coal acreage in Franklin County, Illinois, and commenced operating this tract under the name of the United Coal Mining Co. At the same time the C. M. Moderwell Co. continued to handle other coals than those produced by the United company, until at the present time "C. M." has built up and supplies a market of considerable importance.

A new mine that has just been opened by the United Coal Co. at Christopher, Ill., is properly conceded to be one of the most modern and best equipped properties in the state. The same company also has a small mine in Indiana, at Mecca in Parke County.

Although Mr. Moderwell does not control a great number of mines and an unusually large production, he certainly "cuts a lot of ice" in the councils of the Illinois coal operators. At the recent meeting of the Mining Congress in Chicago he and Carl Scholz were the leading spirits in effecting arrangements for the conference, and the success of this most recent meeting was largely due to his efforts.

Mr. Moderwell firmly believes that conditions in the coal industry in Illinois are certain to get very much worse before they finally improve. Like other men who are well informed as to the true situation in that state, he attributes the present unsatisfactory conditions to the lack of a united front and common understanding on the part of mine owners. "C. M." points out that consolidation is the probable cure, and cites the case of Indiana where six companies control about 75 per cent. of the output.

Due to suicidal competition, Illinois mines last year worked only 182 days, and there is little hope of a betterment in the situation until a few powerful interests have secured control of affairs. The miners themselves, notwithstanding the fact that they have forced greater concessions from owners in Illinois than from operators in any other state, have failed to profit through their seeming victories, for last year the average wages of each mine employee working in one of the collieries of the state was less than $600.

As to sociological work among the miners, Mr. Moderwell holds ideas that are ultra-modern, and he firmly believes that mine owners are often prevented from carrying out a definite plan of welfare work by the unnecessary suspicions of the men themselves. It frequently occurs that an operator is prevented from effecting an improvement at his mines, because of the belief on the part of many employees that there is a "nigger in the woodpile." War has been waged so long in Illinois that the miner cannot realize that the "enemy" may have an unselfish interest in his erstwhile foe.

COAL AGE

Issued Weekly by the
Hill Publishing Company
JOHN A. HILL, Pres. ROB'T MCKEAN, Sec'y.
505 Pearl Street, New York.

Monadnock Bldg., Chicago.
6 Bouverie Street, London, E. C.
Unter den Linden 71—Berlin, N. W. 7.

FLOYD W. PARSONS, Editor.

Correspondence suitable for the columns of COAL AGE solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Entered as second-class matter, October 14, 1911, at the post office at New York, New York, under the act of March 3, 1879.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of Coal Age, we will print 7500 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.

This journal has a direct aim—a single purpose—which is to help advance the coal-mining industry. Its creed embodies the dissemination of knowledge and the free interchange of ideas among its readers, all of whom are invited to become regular contributors.

Contents

Mining Methods and Labor

There is but little opposition today to the introduction of machinery in coal mines. The American workingman takes quite a sane view of its use, and realizes that it increases his earnings and lightens his toil. It is remarkable the change in view which has taken place even in the last decade, for there are few workmen at present who seriously entertain the foolish notion that machinery impoverishes labor. Yet a certain amount of education on the attitude of labor to machinery is needed, and it is not unreasonable to hope it will be effected if sober counsels prevail.

The average miner who works with or after machinery has altogether too much hard lifting and pushing to do. The work referred to is not continuous, but it is hard. The machinery is cumbersome and not much of it is equipped so as to be self-propelling. A common type of machine has to be loaded on a truck, with perhaps a board, flexible hose and other paraphernalia. It has to be pushed to the face of a long room and disembarked. The board is placed and the machine dragged onto it and a sumping cut is made. After a few straight cuts are completed, the machine and board must be pulled back across the face and reloaded, and the truck with its load pushed down the room and up along the heading to the next chamber, ready for cutting. Then all the work detailed has to be duplicated in another room. With machines of other types, the methods are but little different and are often still more laborious. It is to be hoped for the sake of the miner that much of this hard work will be eliminated.

All these difficulties are faults, not of the machines but of our disjointed methods of mining. In many cases, they are the outcome of the room-and-pillar method. This latter plan never was a thoroughly satisfactory system, and the advent of the machine has only made it increasingly undesirable. The more a single cutter will accomplish, the more undesirable it is to provide such meager opportunities for its action.

Gradually we are learning how the many roadways needed for approaching a multitude of working faces makes it hard to maintain any one road in proper shape. Little by little we are grasping the idea that more powder is consumed and more danger incurred when shooting in a tight place. Slowly it dawns on us that the multiplicity of roadways excludes the use of a large car in a thin bed. We are beginning to realize that this old method makes necessary excessive supervision and much work for shotfirers, ribbosses and timbermen.

Moreover, we are commencing to see how hard it is to ventilate the ragged line along which the coal is attacked. Valuable fuel is being lost and the difficulties of drainage and general development are multiplied. We are feeling our way to a point where we shall deplore the inability to use machines for shoveling and conveying.

Hampered in every direction, as in the distribution of power (knowing that one machine will work only from one-third to one-half time), we buy grudgingly, enough cutters to mine the needed coal, but we rarely arrange for sufficient power to operate all the machines at the same time. At least we do not purchase pipes or leads large enough to permit of synchronous working of the machines. So now and then we find a scarcity of power.

But if the machines could cut all the time on a longwall face, this difficulty and all the others would disappear. Our territory would be more compact, more readily supervised, better timbered, piping and wiring costs would be lessened, the ventilation would be better, the coal more easily shot, new types of machinery could be used, large cars loaded and more work done per man employed. Drivers and motormen would not be delayed by the transference of machine trucks along the haulage roads and larger coal would be obtained. Moreover, in thin beds, which now have wide rooms, a double shoveling of coal would be unnecessary. It is true

that the longwall workings of English mines have the disadvantages of high timbering costs and of that increased expense which results from continued road renewals, but the retreating-longwall-by-panels system, now in use in a few American mines, should not involve any of this expense.

However, if the wage rate to the cutter per ton undermined is to be as high on several small working faces as on a long cutting face, if the payment of the loader per ton removed is to be the same whether much or little powder is consumed, and whether conveyer machines are used or not, then every change which benefits labor is to be at the entire expense of capital, and the latter will make no move.

There must be on the part of labor a desire to hasten the introduction of every form of machinery and a willingness to share fairly in the product of lessened effort. The worker must be willing to concede a fair proportion of the advantages of a scheme which lightens his labor and makes possible a greater output per day, seeing that the improvement will be brought about by the expenditure of no little money. The miner should be ready to welcome the opportunity afforded him, not only to make a greater daily wage, but also to work less hard and should not wish to monopolize the just dues of commercial enterprise. Otherwise the cutter, scraper and loader will continue to act as boosters and as mules, and will be delayed and harassed in their work by ill adjusted conditions.

As conditions in unionized districts now exist, it does not seem advisable to adopt elaborations requiring expensive machinery of unusual type, and a reconstruction of the mines with a sure increase of dead work and extra day labor, if the share of the operator in the proceeds is only what can be obtained from the use of a somewhat larger car and the obtaining of somewhat less broken coal. Where coal is weighed before screening, the obtaining of large lumps might alone justify the new methods of working and the introduction of machinery appropriate thereto, but where payment is based on the screened product, it is hard to see what important gain the operator could make unless he received a concession in wage. The use of the face conveyor involves the hiring of car loaders, machinists, engineers and firemen, and as these men all assume a part of the work of the loader, it is but right that a reduction of loading price, not necessarily proportionate, however, should be conceded by him; but always, on the condition that under the new arrangement he shall be assured a chance to earn a better wage than under the old *régime*.

The Pittsburg Rate Case

We have refrained from commenting on the decision of the Interstate Commerce Commission, rendered in the Pittsburg-Lake rate case, until a careful analysis of the text of the verdict could be made. This decision, in its effects on the coal industry, is by far the most important ruling yet made by this court. It is broad in scope, conclusive in its results, conservative to a fault and, most important of all, will become effective almost immediately without further litigation.

We are firm advocates of an equable geographical distribution of the coal markets, and believe that any principle by which the railroads attempt to increase their tonnages or excite unprofitable competition by the imposition of unfair tariffs, is directly contrary to the basic intent of our Constitution. In the opinion of the Commission it was the intention of the railroads to promote such conditions by gradually advancing the Pittsburg rate, "not to bring it up to the level which the carriers might have regarded and defended as reasonable, but to let certain competing coal fields into the lake trade." This disposition on the part of the railroads to be the ruling factor in the destiny of any coal field is a distinct imposition on the industry and one long resented by it.

The ruling provides, in brief, for a reduction in the Pittsburg rate of 11 per cent. and an increase in rates from the Thacker and Pocahontas fields averaging 9 per cent., making a differential on the existing schedule of approximately 20 per cent. What the real material benefits, accruing to the Pittsburg operators will amount to, is problematical. As is well known, the Fairmont and Kanawha fields are the most important competitors in the lake trade and no revision in rates from these districts has been made. On the other hand, it is estimated, on the basis of past shipments from the Pittsburg district, that the reduction will effect a direct saving to the operators of over a million dollars annually. Aside from this, many mines heretofore unable to ship profitably to the lake market will now be in a position to compete actively in this trade. That the ultimate effect will be a marked change and a radical readjustment in long established channels of commerce, is hardly to be questioned.

A careful analysis of the findings of the Commission shows a decided (and commendable) leaning toward conservatism. While the court is of the opinion that on the basis of a ton-mile rate, the differential should be even greater, it says, in part:

> When we consider the disturbance in established differentials, the possible deflection in the currents of coal trade and the effects on the carriers directly involved, we are forced to the conclusion that a rate lower than this would not be just.

And from the further fact that the ruling is made effective only over a period of two years, shows the tentative way in which the Commission regards its finding, and the possibilities of a reversal should it fail to bring forth the desired results.

Dissatisfaction with the decision of the Commission has been expressed in some quarters. There are those who point to the Pittsburg rate of 5.5 mills per ton-mile as compared with the Kanawha rate of 2.4 mills and believe that the revision should be made on this basis. Railroad tariff is a question which has occupied the attention of some of the keenest intellects in the country, and a solution of the problem along these lines has been generally conceded impossible. When it is remembered that the rate on a carload of steel plates from Pittsburg to Chicago is nearly double that on a carload of pianos from New York to Chicago, the utter absurdity of such a contention is at once evident.

The foreman is the chief factor in the prevention of mine accidents. On his personality depends the discipline of the mine. In order to fulfil all the requirements of the ideal foreman a man should have had practical experience in mining, good judgment, enough initiative and strength of character to stand by his ideas and make others respect them. He should possess sufficient tact and knowledge of human nature to control the men under him, and be temperate and truthful.

Colliery Notes and Comments

Practical hints gathered here and there, and condensed to suit the busy reader

The Appalachian coal field is the richest coal deposit in the world. It produces nearly one-third of the world's coal.

Lethbridge and the Pass district produced over 6,000,000 tons of coal last year. Fifteen years ago the same region produced less than 200,000 tons a year.

A succession of small shots is much better than a few large ones. Holes should be drilled so that advantage may be taken of all partings. Load the coal out before firing a second charge.

A Scotch device for removing dust from coal mines consists of electrically-worked air-jets and a suction-device which simultaneously raise and withdraw the dust.

Experience has shown that the wet zone method of preventing the spread of an explosion is not to be depended upon. With very intense heat, thoroughly wet zones, 150 ft. long, have been crossed by the flame.

A method of removing carbonic dioxide sometimes employed in English mines, is to spray the mine with hypochlorite mixtures in liquid form. The hypochlorites of the alkalies have the property of absorbing carbonic dioxide when such is present.

Experiments made in France have shown that watering thoroughly for 10 yards in front of shot holes in dusty mines will greatly reduce the dangers resulting from blowout shots. While ignition was not always prevented, it in no case extended more than seven or eight yards.

Precautions to prevent gob fires are: (a) So far as is possible, withdrawing all timber from the gob; (*b*) stowing the waste with all the dirt available; (*c*) giving great attention to the building of gate-side pack-walls; (*d*) leaving no pillars or ribs of coal; (*e*) keeping the workings cool by means of ventilation, but excluding the air from the gob.

Leaders of rescue corps should bear in mind that while rules and regulations are desirable for intelligent action, it is impossible to lay down hard and fast rules for rescue work at explosions and mine fires, as circumstances vary and each mine and each fire or explosion furnishes a different problem in itself, and nothing can replace individual intelligence and decision on the part of the leader of the corps.

Developments in mining, in Alberta province, Canada, during the past five or ten years, have produced great changes. Seven large and well equipped collieries now dot the plains, and some of these are said to have the most up-to-date steel tipples in the world. There has been, in this time, a vast development of coal areas in the "Pass," known better as the Crows Nest Pass, on the C. P. Ry., and on the line dividing the provinces of Alberta and British Columbia.

Pure calcium chloride will absorb as much as 1.15 times its weight of water. When intended for use on dusty roadways, gobs, or floors of entries, it should be bought in the granulated form as it is then much easier to spread evenly and is more effective than when either in the solid or dissolved form. But for use on ribs, roof, and timbers five or six pounds should be dissolved in 100 lb. of water and this mixture sprinkled by means of the water car and hand pump.

Discussing the types of available breathing apparatus, Mr. Blackett says there are two forms from which to choose, namely, (a) that which maintains its supply of oxygen from steel cylinders containing the gas compressed to, say, 120 atmospheres, and which has the expired carbonic-acid gas absorbed by such a substance as caustic potash, and (b) that which depends upon liquid air boiling off and being discharged into the surrounding atmosphere, instead of being, as it were, regenerated.

Spontaneous combustion is now recognized as the greatest problem to be overcome in connection with the storage of bituminous coal. One good method of detecting an incipient fire is to have all storage bins fitted out with temperature tubes, using 4-in. galvanized pipes, about 20 ft. long, set in the floor of the bins in such a manner as to project upward into and through the coal pile. Each tube should be provided with a thermometer which is capable of indicating temperatures over 150 deg. F. Run a circuit from each of the tubes to an alarm bell in the office of the yard superintendent so that if the coal is heating an alarm will at once be sounded.

Great Britain has no law touching the kind, or length of service of hoisting ropes. The law limits itself to holding the mine owner personally responsible for any mistake he may commit which results fatally, but so far as the law is concerned any kind of rope may be used and may be kept in use as long as the mine management desires. Superintendents are obliged to report all rope breakage regardless of whether any persons were either killed or injured. In the last 10 years Great Britain has had only 38 fatal accidents due to the breakage of hoisting ropes. Only a few British mines test their ropes themselves; the tests are made by the rope manufacturers. It is far less customary to test the finished rope than the individual wire.

Prussian mining authorities prescribe the following tests for hoisting ropes used in shafts where men are lowered and hoisted. Each rope must be subjected to tensile and bending tests performed on a 40-in. length cut from the rope. The tests must be applied to each wire in the rope, except the core wires of the several strands and of the entire rope. Each wire must be loaded to its breaking point and its limit of flexion must be ascertained by bending it through an angle of 180 deg., on a 5mm. (0.2 in.) radius until it breaks. The number of bends must be counted. Each test for flexibility is carried out by bending the wire alternately from right to left, through an angle of 90 deg. from the vertical to the horizontal position and on to the vertical position. The carrying power of the whole rope is calculated by adding together the weight required to break each individual wire, with the exception of the cores, leaving out of consideration all wires whose carrying strength is 20 per cent. below the average of the whole. Ropes made of wire, other than plain section must have their carrying power determined by straining the whole rope or whole strands to the breaking point. All hoisting ropes must be tested at least once every three months. When the strain on the rope is light, longer intervals may elapse between testings, by cutting off at least 10 feet from the end attached to the cage, above the capping; 40 in. of the top part of the cut-off portion must be tested for tensile strength and resistance to flexion in the same manner as prescribed for new ropes. Every hoisting rope must exhibit at least a margin of safety of 6, referred to the maximum load carried when hoisting animals. When hoisting men the weight on the cage must not be more than ½ the weight carried when hoisting coal.

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Spontaneous Combustion

Under the above caption much has been written and said by many experts and scientists. Yet it seems there are a few practical things picked up in a life's experience around mines, that might be said. The reason some coals ignite without the application of fire, and others do not, is as mysterious and paradoxical as the coking qualities of coal.

Most writers agree that iron pyrites (FeS) is the principal cause of spontaneous combustion, but I do not agree with this theory. Although the bisulphide of iron is always found in gob fires, I have always understood that no fires have ever taken place in coal piles or gobs except where proto sulphides were also present, as for example in the Yorkshire and South Wales tests. This is true at least, in all cases where these gobs and coals have been subjected to ultimate analysis. Also, quite a number of experts do not seem to distinguish between the gases that compose the coal and those occluded in it.

Furthermore, few people have considered the nature of these occluded gases sufficient to thoroughly understand the origin of the gob fire. Most writers seem to infer that the temperature of spontaneous combustion is quite high, about 700° to 1000° F.; to this again I cannot agree. Many men who have traveled over gobs and the waste in abandoned workings have no doubt noted the extra heat of the top coal, slack and bituminous slates.

This, I understand, to be spontaneous combustion in its initial stage; it may be as low as 80° F. or so hot you cannot hold your hand on it, yet the actual fire is not yet due by many degrees. It seems possible that, in the disintegration of the coals, enough heat is generated to throw off one S from the FeS_2, thereby forming the proto-sulphide FeS and SO_2. At any rate I am positive, there is plenty of this sulphurous oxide generated long before any glowing fire appears.

Your correspondent stated that water or vapor helped the combustion and it may be the HO is given off, and with the free S forms the SO_2. However, I do not think so, as it always has been my experience that the drier the gobs the more liable they were to fire, and I have never seen a fire in a wet gob. But to return to the temperature, I believe that when combustion has advanced enough to produce large quantities of SO, it may be stopped and the temperature made normal.

I firmly believe that, if waste workings were thoroughly ventilated, there would be no gob fires. At our mines here four years ago we holed a butt heading out to daylight. On the rise side of this heading was old workings about 2000 ft. by 1500 ft., all abandoned; through this heading we hauled the coal from another mine by electric motors. The mine inspector and I had often noticed the dry SO_2 coming along this haulageway in the suction of the trip; there was enough to make you cough and sneeze. Beyond these workings there was a large block untouched, which it became necessary to develop. We discharged into the old workings 35,000 cu.ft. of air per min., as per the state mine inspector's report. The result is that the pungent odor is gone, and the old entry that once fatigued you, and made your eyes ache in a 1000-ft. travel can now be traveled with impunity.

Therefore, my firm opinion is, that the cause of the most of the spontaneous ignition in mines is principally the lack of proper ventilation. I have such faith in the theory that I have recently suggested a plan to ventilate coal stock-piles.

JOSEPH VIRGIN.

Plymouth, West Va.

[Our correspondent has presented some interesting, and we believe original theories, on this much discussed question. He has, however, evidently been misinformed or been referring to unreliable authorities. The most recent investigations on this subject are embodied in a paper presented by permission of the Director of the U. S. Bureau of Mines at a joint meeting of the New York sections of the American Chemical Society, American Electrochemical Society and the Society of Chemical Industry, New York City, Nov. 19, 1911. On the subject of spontaneous combustion this paper says:

> Oxidization (probably in the main an absorption of oxygen by unsaturated chemical compounds) begins at ordinary temperature in any coal, attacking the surfaces of the particles and slowly developing heat. In a small mass of coal this heat can readily dissipate itself by radiation and no rise in temperature results. If radiation is restricted, however, as in a large pile densely packed, the temperature slowly rises. Now, the curve of oxidation rates, plotted against temperature, rises with great rapidity, and when the storage conditions are such as to allow the temperature of about 100° C. to be exceeded, the rate of oxidation is great enough ordinarily, so that the heat developed overbalances the heat radiated. Then the temperature rises to the ignition point if the air supply is adequate.

According to this hypothesis, spontaneous combustion is accelerated by the exclusion of air until the temperature of 100° C. is reached, after which combustion is aided by the admission of air. We would be pleased to hear from other readers on this very important subject.—EDITOR.]

Testing for Gas with a Normal Flame in the Wolf Lamp

In my experience with a Wolf lamp burning naphtha, I have observed that when a ¾-in. or normal flame was used for testing purposes the lamp would not give any indication of the presence of gas, except that the flame became somewhat smoky. In one instance, recently, there was a uniform mixture of 3½ to 4 per cent. of marsh gas in the air at the time of making the test. In using the normal flame, I could get no indication of gas. When the flame of the lamp was reduced, however, to what may be called a standard or capping flame, a ⅜-in. to ½-in. cap was formed. I would like to know if others have had the same experience in the use of the Wolf lamp.

After studying the matter, I came to the conclusion that the air or mixture of air and gas, which entered the lamp through the gauze ring below the flame, was only sufficient to support the flame and burn a very small amount of gas that acted to keep the height of the flame constant. My idea was that when a larger flame was used, the air entering the lamp was not sufficient to produce complete combustion, which fact caused the smoky appearance of the flame; and this, together with the brightness of the large flame, obscured the cap. It is a common practice among some firebosses to test for gas with the normal flame in the Davy lamp; but this lamp has a large intake area providing a better circulation in the lamp than is true for the Wolf lamp. When using the normal flame in testing for gas, to obtain reliable results the flame, in gas, should reach to the top of the globe, in the lamp, or nearly so. To determine the percentage of gas, however, a reduced or standard or capping flame should be used.

BENJAMIN HARTILL.

Johnstown, Penn.

[In this connection, the article "Estimating Gas Percentages," COAL AGE, Dec. 2, p. 250, is of interest.—EDITOR.]

Inquiries of General Interest

All Questions Must be Accompanied by Name and Address—Not for Publication

Motive Column and Velocity

I want to ask (a) what will be the height of motive column produced by the difference of temperature in two shafts of equal depth and area, the depth of each shaft being 700 ft.? The temperature of the downcast is 40° F. and that of the upcast 65° F. (b) What would be the velocity of the air current?

INQUIRER.

(a) The height of motive column depends only on the difference of temperature in the two shafts, the density of the air and the depth of the shafts. The area does not affect the motive column. The upcast air being the lighter, a motive column of this air will be longer, for the same conditions, than a column of the heavier downcast air.

Downcast air

$$M = 700 \times \frac{65 - 40}{460 + 65} = \frac{700 \times 25}{525} = 33\tfrac{1}{3}\ ft.$$

Upcast air

$$M = 700 \times \frac{65 - 40}{460 + 40} = \frac{700 \times 25}{500} = 35\ ft.$$

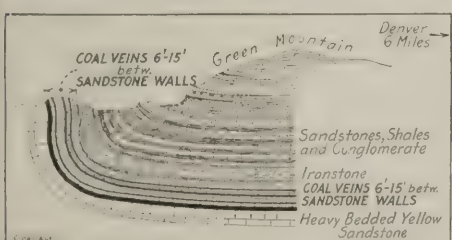
(b) The theoretical velocity due to the head of air column in either case is given by the formula

$$v = \sqrt{2\,gh} = \sqrt{2 \times 32.16 \times 35}$$
$$= 47.4 + ft.\ per\ sec.$$

This, however, has no practical bearing, here, as it represents the rush of upcast air into a vacuum only; and has nothing whatever to do with the velocity of the upcast current in the shaft.

Thick Vertical Coal Seam

I was greatly interested in the inquiry of Chas. M. Sherman, COAL AGE. Apr. 6, p. 851, asking for a discussion of the best method of developing a vertical coal seam, 16 ft. thick, 1000 ft. deep and



GEOLOGICAL CROSS-SECTION OF COAL SEAMS

one mile long. This is a pertinent question and one we also would like to see discussed, inasmuch as we are facing a similar proposition here, having just opened a vein that could be described in the same words. At the present writing, we have sunk a 5x8 ft. prospect shaft, 110 ft. deep, and from the bottom of this shaft have driven entries, each way, 300 ft., in the coal. The seam measures 16 ft. thick and stands at an angle of about 87°; it extends downward fully 1000 ft. and has a width of 2 miles on the property.

We shall watch with much interest the replies to this question. We inclose a sketch showing the cross-section of the formation here, taken from the report of the Geology of Colorado Coal Fields.

W. B. HOUSE, GENL. MGR.
The Rooney White Ash Coal Co.
Denver, Colo.

Detection of Carbon Monoxide Gas in Mines

Among the questions answered in COAL AGE, Mar. 9, p. 720, I notice one asking how to detect mine gases, or rather, to describe the effect of the different mine gases on the flame of a safety lamp.

I would like to ask if the manner in which this gas is commonly described, especially with regard to its action on the flame of a lamp, is not a dangerous and misleading way of putting it. All text books, in speaking of carbon-monoxide gas, refer to the lengthening of the flame in the gas and add, the flame burns more brightly in this gas than in air. This must be true since *all* books on mining say the same thing; but they do not give the percentage of gas necessary to produce this effect. My question is, does not this statement lead the miner to depend upon his lamp to show this gas and often cause him to lose his life in the attempt to rescue friends, after an explosion?

If I am not mistaken, it takes 3 per cent. of CO to show this effect; but ½ of 1 per cent. of this gas is fatal to life. If this be true, a man would die before his lamp would reveal the danger. I do not wish to be understood as a critic, but I have seen foolish men lose their lives in the manner stated, depending on the light to show this gas. It may have been because of the books they had read; but I think this matter should be made clear by an article on this gas alone, especially as so few miners understand the danger to which they are exposed in its presence.

JAMES R. CAVANAUGH.
State College, Penn.

Our correspondent has drawn attention to an interesting and important point. While it is probably true that more has been written, of late, drawing attention to the dangerous character of this gas than can be said of any of the other mine gases. much of what has been written is misleading in the daily practice of mining, because undue emphasis has been placed on the physical properties of the gas, the effects of which, in most cases, are not understood by the ordinary miner.

The answer to the question to which our correspondent refers, however, in COAL AGE, Mar. 9, p. 720, distinctly states: "However, it is unsafe to rely wholly on these indications for its (CO) detection. Other means should be used, as the blood test or the canary or mouse test." The answer to the question immediately preceding this one draws attention to its dangerous character, which is due chiefly to the fact that lamps "continue to burn brightly in the presence of this gas".

In regard to the percentage of gas required to produce the effect described, it is impracticable to say; because, the gas being combustible, its presence in the air surrounding a flame adds to the combustion and maintains a higher temperature over the surface of the flame. A very small percentage of the gas increases the brightness visibly, and the effect is greater as the percentage of gas is higher. Just at what point the effect becomes appreciable depends on the quickness of the observer to detect the change.

Furthermore, the presence of fine coal dust floating in the mine air will produce the same effect, lengthening and brightening the flame, when no carbon monoxide is present except that which may be generated by the burning of the dust in contact with the flame. On the other hand, the presence of blackdamp destroys the effect of carbon monoxide on the flame more or less completely, while it does not, to the same extent, destroy the toxic effect (effect on life).

For these reasons the effect produced by this gas on flame, as commonly described, though true for even low percentages, must not be taken as a safe guide or test. The same remarks apply, though less forcibly, to the detection of firedamp, the flame test being modified here also by the presence of other gases. A dangerously explosive mixture of marsh gas, carbon dioxide and air (flashdamp) is frequently mistaken for a harmless body of gas or overlooked entirely, because the cap only appears as a momentary flash on the lamp and is gone.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Ellsworth Mining Institute, Tennessee

MINE FOREMEN'S CLASS, QUESTIONS

Ques.—Describe, in a general way, the duties of mine foreman, superintendent and all other employees inside of a mine.

Ans.—The mine foreman is the responsible man in the operation of a mine. He has full charge of the mine, its equipment and supplies. His duties are to direct and supervise the entire work of the mine, examine and control its ventilation, inspect all machinery and the inside workings, provide the necessary supplies and receive the daily reports of the men in his charge. He must personally superintend the prompt removal of all known dangers or order the men to withdraw from the mine.

The superintendent plans the work, receives and files all daily and monthly reports, fills all orders for supplies made by the mine foreman, inspects the mine maps, time sheets and all bills of expense, directs the loading and shipment of coal, and regulates the output to meet the demand.

The fireboss examines the mine for gas and to discover any dangers or unsafe conditions before the men enter the mine in the morning and during the day while the men are at work in their places. He should place danger signals where such are needed, give all necessary instructions to miners, regarding the use of their lamps, the drilling of holes for blasting, charging and firing shots, and the timbering of their places, loading of cars, and whatever may be necessary to safeguard life and property.

The boss driver directs the other drivers in the work of transporting the coal from the working face to the parting or shaft bottom. The timbermen and trackmen look after the timber and track in all roadways, take down loose rock and lay room switches as these are required.

It is the duty of miners to carefully inspect their own working places and set any timber that may be required before starting any other work. All employees should report promptly any dangers they may find to the mine foreman or his assistant.

Ques.—What quantity of air is passing in an airway 5x7 ft. when the velocity is 250 ft. per min., and what record should be made in the mine-record book of such measurements?

Ans.—The area of the airway is

$$a = 5 \times 7 = 35 \text{ sq.ft.}$$

The quantity of air passing is then

$$q = av = 35 \times 250 = 8750 \text{ cu.ft. per min.}$$

The date of the observation, sectional area of the airway, anemometer readings, velocity of the current and the calculated quantity of air passing should all be promptly recorded in the book kept for that purpose and the entry signed by the one who made the observation.

Ques.—What is meant by splitting the air current in a mine, and what effect has it on the total volume of air in circulation?

Ans.—By splitting the air in a mine is meant dividing the air current into two or more separate currents. By this means the total volume of air is increased, assuming the power producing the circulation remains unchanged. Owing to this increased volume of air having to pass through the fan, the shafts and the main airways, its velocity in each of these is increased in proportion to the increased volume of air, but the velocity in each of the splits is decreased somewhat. However, owing to the number of splits the total quantity of air in circulation is always increased.

Ques.—If a current of 30,000 cu.ft. of air is passing into a mine and you find only 5000 cu.ft. at the working face, how would you account for this loss and how can it be prevented?

Ans.—The loss in the volume of air that reaches the working face is due to leaky stoppings, doors, air bridges and brattices used to conduct the air throughout the mine. If these are not made air-tight the current or a certain portion of it will be short-circuited at such points and pass into the return, thus failing to reach the face. It can be prevented by repairing or rebuilding all stoppings, doors, brattices, etc., that leak air.

Ques.—If an airway 2000 ft. long and 6x8 ft. in section is passing 50,000 cu.ft. of air per minute, and another airway of equal size is added, what will be the total quantity of air passing per minute in the two airways, the pressure remaining constant?

Ans.—The question is a little indefinite as to its meaning. Assuming, however, that the airway added is another and separate split affected by the same pressure as the original airway, the total quantity of air will be doubled, since each airway will then pass 50,000 cu.ft. per min.

On the other hand, if the new airway is an extension of the original airway, whose length will thus be doubled, the quantity of air that will then pass through this long airway will be decreased. For the same pressure per square foot the quantity varies inversely as the square root of the length. More simply, for the same pressure, the quantity ratio is equal to the square root of the inverse-length ratio (the cross-section of the two airways being the same). Thus, the length ratio in this case being 2, and calling the required volume of air x,

$$\frac{x}{50{,}000} = \sqrt{\frac{1}{2}} = \sqrt{0.5} = 0.707$$

$$x = 50{,}000 \times 0.707 = 35{,}350 \text{ cu.ft. per min.}$$

Ques.—What provision should be made inside a mine to insure its being properly ventilated?

Ans.—All stoppings, brattices, doors and air bridges must be made air-tight. Doors must be substantially built and hung so as to close with the air. Double doors must be used at all main points separating the main intake and return airways. Other doors on haulage roads where much coal is passing should be trapped. All air crossings should be built as overcasts and not undercasts. Airways and crosscuts should be kept free of all obstructions of any nature; empty or loaded cars should not be stood in airways, but in the mouths of rooms or on partings where they will not obstruct the flow of air. The air current should be distributed so as to proportion the quantity of air in each split to the requirements therein. Special brattices should be used to make the air current sweep the face of each working place. The velocity of the current, at the face, should always be sufficient to sweep away all gases and prevent their accumulation in any void or abandoned places. The velocity in the workings should not exceed 480 ft. per min.

Correction

The answer to the last question, Pumping Calculation, COAL AGE, Apr. 13, p. 887, made the actual discharge greater than the theoretical discharge, which, of course, is wrong. The answer should read.

(b) Actual discharge,

$G = 0.85 \times 705 =$ say, 600 *gal. per min.*

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

The House Committee on Mines and Mining has reported favorably on the Foster bill, which provides for the creation of a Commission of Mining Industry, with power to undertake a general investigation of mining conditions throughout the country. The commission is to be composed of 11 persons, as follows: Two members from the Senate and two from the House, two representatives of the operators, two representatives of the miners, two engineers and a representative of the Bureau of Mines.

It is to be the special duty of this commission to inquire into labor conditions in the mining industry and to seek to discover and point out the underlying causes of dissatisfaction, also to inquire into mining methods with regard to their safety and efficiency, and the general conservation of mineral resources.

Rates on Colorado Coal

A decision by the Interstate Commerce Commission in the case of the Nebraska State Railway Commission vs. the Chicago, Burlington & Quincy R.R. Co. *et al.* explains that in the application of rates on coal from the Walsenburg district of Colorado to numerous points in Nebraska the defendants provide a rate of $3.50 per net ton to one group of stations and a rate of $3.75 to a second group. The complainant, in substance, asks that certain points now taking the $3.75 rate be included within the $3.50 rate group, and the certain points taking the $3.50 rate be divided into two new groups to which shall apply rates of $3 and $3.25, respectively. The rates involved have been considered, and it is held:

(1) That the defendants subject Minden "K" to undue and unreasonable prejudice in charging a higher rate than applies at Minden, and that for the future the rate to Minden "K" should not exceed the rate contemporaneously maintained to Minden.

(2) That, under the readjustment required by this finding, the rate to Minden "K" should not be exceeded at the intermediate stations of Keene, Wilcox, Ragan, Huntley, Alma, Orleans, Carter, and Sacramento.

The Commission further explains that:

A careful analysis of the reports filed with the Commission by the defendants, the Chicago, Burlington & Quincy R.R. Co., the Colorado & Southern R.R. Co. and the Denver & Rio Grande R.R. Co. shows that the operating expenses per ton-mile over these lines is so high that we hesitate to make changes in the rates now under investigation other than those noted.

Alabama

Birmingham—The coal operators of Alabama are making an advance in wages, effective May 1, amounting to 2½c. per ton mine-run for pick mining in the Pratt seam of coal, which is the basing seam for the state. This will advance the Pratt pick-mining rate from 52½c. per ton to 55c., and other seams will be advanced in proportion. The yardage and day rates will be advanced about 5 per cent.

Tests have been made recently by Chief Mine Inspector Nesbitt to determine the percentage of gas in the air of several Alabama mines. The apparatus used was that installed here lately by the government. The samples were taken largely from the Flat Top and Indio mines and, in most cases, showed less than one-half of 1 per cent. of explosive gas.

Colorado

Denver—A proposed increase of 35c. per ton in the freight rates on coal from the Walsenburg district in Colorado to points of destination in Kansas, Oklahoma and Texas, was suspended, Apr. 10, by order of the Interstate Commerce Commission, until Aug. 12. The new rate was to have become effective Apr. 14.

By a recent decision, the Interstate Commerce Commission has ordered a reduction in freight rates on coal from the Walsenburg field to points along the Burlington road as far east as Oxford Junction, Nebraska. A reduction of 25c. per ton is applicable to the stations of Ragan, Huntley, Wilcox, Sacramento and Minden. The following stations between Minden and Superior must continue to pay the old rate: Superior, Edgar, Clay Center and Harvard.

Illinois

Chicago—The Illinois United Mine Workers have voted to accept an increase of approximately 5c. per ton of screened coal and to return to work May 1.

Mount Vernon—The Chicago Coal Co., of Chicago, has procured options on 3000 acres of coal land in Jefferson County, and it is reported that the purchasers expect to open a number of mines during the present year.

Coal City—The head works of mine No. 3, at Tower Hill, were blown over by the storm, Apr. 21, which did great damage in this vicinity.

Belleville—One hundred and twenty-eight miners have brought suit against the Royal Coal & Mining Co., the Wilharmil Coal & Coke Co., and R. W. Ropiequet, for $12,800, wages due them.

Columbia—The East St. Louis-Columbia-Waterloo Electric Ry. has obtained a permit to extend its line through East St. Louis, to enter St. Louis over the Eads bridge. The line will extend from East St. Louis to Waterloo, and will tap coal fields that at the present time have no freight facilities.

Peoria—The scale committee and executive board of the Illinois United Mine Workers arranged to meet the Illinois coal operators, including those from the Fifth and Ninth districts, in conference here on Apr. 23. Differences between the miners and operators will be discussed and any agreement which may be reached will be submitted to a referendum vote of the miners of the state.

Articles of incorporation were recently issued to the Mid-Valley Coal Co., which is capitalized at $80,000, with offices in Peoria. The new company has purchased 500 acres of coal land four miles north of Chillicothe and will begin operations as soon as the suspension of work in the coal mines is over.

Hillsboro—It is reported on good authority that the New York Central R.R. has purchased, or is about to purchase, 15,000 acres of coal lands in and around Ohlman. The field is that optioned a few months ago by Harry S. Hargrave, and sold to St. Paul coal-land men. The mining conditions at Ohlman are more like those at Pana than at Hillsboro, and therefore are not quite as good as conditions here. The vein is about 7½ ft. thick.

Indiana

Indianapolis—The completion of the work of the tellers of the United Mine Workers shows that the bituminous miners have ratified the Cleveland compromise agreement, governing Illinois, Indiana, Ohio and western Pennsylvania, by a vote of 109,709½ to 32,139½. Thus 77 per cent. of the 141,849 miners who voted at the referendum balloting, Apr. 10, favored the agreement. Not later than May 1, it is said at the international headquarters, the 240,000 bituminous miners

will be back in the mines. Approximately 150,000 of these are idle at the present time. The formal signing of the contract which is to bind operators and miners in the four-state field until Mar. 31, 1914, is expected to take place this week. In only one district in the country was the majority of votes cast against the agreement. That was in the Kentucky field, where a total of 1220 votes was cast, 566 of these being for and 654 against the agreement. Of the miners in the districts in Pennsylvania, Ohio, Indiana and Illinois, the four states governed by the contract, 82,066 voted for the agreement and 23,300 against it.

Brazil—The Crawford Coal Co. has begun the work of sinking a new mine northeast of this city, along the Chicago & Eastern Illinois R.R. When completed it will employ 200 or more miners. This enterprise will prove a big help to Brazil, commercially. The new mine is in the Clay County block-coal field and bids fair to run for many years.

Bloomington—Although Monroe County has never been known as a coal producing district, John H. Koontz, who owns a large farm 8 miles west of Bloomington, has found a 4-ft. vein of bituminous coal of excellent quality on his land. It is announced that a company is being formed to develop the find.

Terre Haute—The convention of the Indiana United Mine Workers, which adjourned early in March, pending the interstate conference at Cleveland, reassembled here Apr. 17. The scale committee has prepared a contract to be submitted to the operators at a joint conference. A mutual casualty-insurance agreement will be discussed by both bodies. The operators offered to take up the matter several years ago, but the miners then believed they would succeed in obtaining a state law similar to the one in Illinois.

Kentucky

Whitesburg — The Consolidation Coal Co. has bought 76 acres of coal lands near Jenkins for $19,700. This is at the rate of a little more than $250 an acre—perhaps the largest price ever paid for mountain coal lands.

Louisville—While a final settlement of the difficulties between the union miners and the operators of western Kentucky has not been reached, the only points at issue now are minor questions in regard to working conditions. The wage scale agreed upon has been submitted to a referendum vote. The union miners of southern Indiana have refused to raise funds to be used in an endeavor to organize the non-union territory of western Kentucky.

The entrance of the Norfolk & Western into the eastern Kentucky coal fields is a development of interest. It will make the move through the Williamson & Pond Creek R.R., which was recently organized. This road will be built from Williamson, W. Va., along Pond Creek to a point near Elkhorn City, which is the center of the new coal territory now under development. It is largely for this reason that the Norfolk & Western is rebuilding its bridge over the Ohio at Kenova, W. Va., as it expects to handle a large tonnage of coal as soon as its new connection is built. The Carolina, Clinchfield & Ohio is building from Dante, Va., to the Elkhorn field, while the Chesapeake & Ohio is also entering that district.

Henderson—The Keystone Mining & Manufacturing Co. has filed a suit against the Louisville & Nashville R.R. Co., in which damages of $50,000 are asked. The company's claim is that the road failed to furnish it with cars and to quote reasonable rates on the shipment of coal from the mines to the city of Henderson, and that as a result it was found necessary to close down the mines.

Madisonville—An explosion of gas in the Coil Co.'s mine near this city, the night of Apr. 21, set the mine on fire and probably caused the death of Joseph Hallowell, a mine foreman, and four negroes. Flames were found issuing from the entry and one of the cages was blown out by the explosion. The mine is a new one, about 200 ft. below the surface and only about half a mile long. Only the five men were in the mine.

Greenville—J. W. Lam, Greenville, has purchased the coal mine of the Dovey Coal Co. at Mercer. The purchase price was $75,000. Mr. Lam is one of the creditors of the company, which is in bankruptcy, with liabilities of $100,000.

Missouri

Kansas City—A sub-committee of six members, representing the coal operators and the miners, respectively, in the fields of Kansas, Oklahoma, Missouri and Arkansas, began negotiations, Apr. 16, for the writing of a new two-year contract. The conferences were held in the offices of the Central Coal & Coke Co. An early settlement of the differences between the two sides is expected. The miners by a referendum vote have approved the Cleveland agreement, and it only remains now to agree on the contract. The only serious obstacle in writing the contract pertains to the arbitrator in matters of dispute. The miners desire to eliminate this clause and the operators desire to retain it.

St. Louis—The freight traffic officials of the various railroads entering St. Louis, have practically decided upon a new coal arbitrary, making the rate on all coal the same to St. Louis as to East St. Louis.

Ohio

Zanesville—Fire broke out, Apr. 18, in the shaft mine No. 302, near Congo, Ohio, in which 400 miners were employed until the suspension of work on Apr. 1. A hundred men at once started to work in an effort to check the flames, and several of the fire fighters were overcome by the fumes.

The announcement was made recently in Columbus, that capitalists of that city have leased 8000 acres of coal lands between Durant and Blue Rock. This is one of the biggest coal deals in the history of this section of the state. It was further announced that the old Stone mine at the mouth of Coal Run will soon be purchased and operated.

Columbus—Figures given out from Indianapolis, show that the proposition of remaining at work in accordance with the Cleveland agreement was ratified by the United Mine Workers in western Pennsylvania, Ohio, Indiana and Illinois. The vote against the proposition was unexpectedly large, and hard to account for. The Hocking Valley field is expected to be one of the first to resume operations, as everything is in readiness for resumption. The eastern Ohio field will also resume work soon, and the same is true of the Pomeroy-Bend field. It may be a little time before operations are resumed in the Massillon and Crooksville fields. According to the Cleveland agreement there should be no difficulty in working out the district rulings. The agreement provides that nothing shall be changed to make the cost of mining greater, and, on the other hand, nothing shall be changed to decrease the earnings of the miners.

The Symmes Coal Co., of Ironton, has been ordered by Judge Corn, of the common pleas court of that district, to liquidate claims amounting to $705,204 within the next 45 days. Failure to comply will result in a sheriff's sale of valuable coal lands, owned by the company in Lawrence and Gallia Counties. Of the indebtedness, $700,000 is for outstanding bonds and the balance for notes and court costs.

Bridgeport—President John Moore, of the Ohio miners, with the subdistrict officials, on Apr. 16, visited the towns of Bradley, Piney Fork and Plum Run, where serious riots occurred recently, when pumpers and other repair men working in the idle mines were assaulted by foreigners.

Coshocton—A 5-ft. seam of coal was uncovered recently in the new entry of the Locust Grove Mining Co.'s mine, just south of town. A number of additional men will be employed as soon as the entry is put in shape to start operations.

St. Clairsville—It is not believed the mines of eastern Ohio will resume operations before May 1. While the returns from Indianapolis announcing the majority in favor of returning to work, will al-

low the miners to proceed toward making contracts, vet it is believed the operators are not desirous of resuming.

This is due to reports that none of the large consumers is out of coal and also because many of the markets are still overstocked. Should the mines resume at once the operators would be unable to get the normal price for their coal. With the opening of the Lake trade, however, it is expected all the 17,000 miners in the eastern Ohio field will resme work

Pennsylvania

Bituminous

Pittsburg—The annual convention of District No. 5, United Mine Workers, broke up in disorder and a "rump" meeting, Apr. 18. The 50,000 idle miners in western Pennsylvania will return to work at once. It was announced that notifications had been sent to the various locals to have the men return to work.

Dubois—The joint scale committee of District No. 2, United Mine Workers, after two weeks of deliberation, reached an agreement, Apr. 20. The scale is somewhat lower than the miners demanded, particularly in regard to dead work. It is signed for two years and is as follows: Pick mining per gross ton, 72c.; pick mining per net ton, 64.29c.; machine loading per gross ton, 42c.; machine loading per net ton, 37.23 cents.

Boswell—A fire, on the morning of Apr. 12, destroyed the large outside barn at the Merchants' Coal Co.'s mine, and a number of mules were burned to death. The loss, including damage to a nearby dwelling, is estimated at $3500.

Charleroi—In accordance with instructions posted, Apr. 17, nearly all the mines of the Monongahela River Consolidated Coal & Coke Co., the Vesta Coal Co. and various other smaller companies with mines along the Monongahela River, resumed operations Apr. 18. This ended a suspension lasting since Apr. 1.

Brownsville—The Knob mine of the Monongahela River Consolidated Coal & Coke Co., idle since Apr. 1, resumed operation, Apr. 19. The Albany and Chamouni mines of the same company resumed work, Apr. 22. About 1500 men are affected.

Connellsville—The Connellsville coke trade is in the unfortunate position of not being able to supply the demand because of inadequate and uncertain labor conditions. While labor has been coming into the coke region slowly, it has not come in sufficient volume to meet the requirements of the situation. Production for the week ending Apr. 13 fell off 52,175 tons, as compared with the week before, the total being 363,289. The decrease was evenly divided between the furnace and merchant ovens, that of the furnace ovens being 26,356 tons, their total being 230,732, while the merchant ovens fell off 25,819 tons, their total being 132,913.

Anthracite

Scranton—Following a conference with the board of directors of the Scranton Board of Trade and a committee from the West Scranton Board of Trade, the city council recently received a resolution directing the city solicitor to prepare an ordinance putting into effect the police powers of the city to prevent mine caves. The resolution was referred to a committee and will probably be passed at the regular meeting of council.

A pumpman at the Moosic Mountain colliery, near Jessup, was shot from ambush while on his way to work, Apr. 16. The attack was made near the point where the railroad tracks were dynamited some days ago. This workman had been sticking to his post during the suspension, in accordance with the arrangement between mine workers and operators. It is thought that some of the miners regarded him as a strike breaker.

More than 300 men and women, gathered at the Raymond colliery at the "Ridge," Archbald, at 6 o'clock in the morning of Apr. 20 to enforce the suspension order. When the men began to report for work the crowd chased home every workman except pump-runners, engineers, stable men, firemen and necessary repairmen permitted to work under the suspension order. There was no rioting or lawlessness, the crowd simply asking the workmen to go home and the workmen obeying the request.

Wilkes-Barre—The Plymouth Coal Co. has complained to the Interstate Commerce Commission of the rates on anthracite coal in carloads from the Dodson colliery and the Black Diamond colliery and other points on the line of the Pennsylvania R.R., to South Amboy, N. J. The commission was asked to reduce these rates and award reparation to the complainants.

The committee, which is conducting the negotiations between anthracite miners and operators, reconvened in New York, Apr. 16, and has since continued its deliberations in that city. Up to the present writing, no definite news has been given out concerning the progress made by this committee toward reaching an agreement. It is currently reported, however, that the discussion of all questions has been fully and freely entered upon, and that an amicable settlement of present diffculties is expected. As has been anticipated, it is said that the demand of the miners for recognition of their organization forms the chief obstacle in the way of reaching a settlement.

Mt. Carmel—A miners' accommodation car on the Reading railroad, near the Philadelphia & Reading Coal & Iron Co.'s Alaska shaft, was blown to pieces, Apr. 17, by dynamiters. A passenger train had passed the siding on which the car lay one minute before the explosion occurred. A detail of coal and iron police are hunting for the dynamiters.

West Virginia

Moundsville—An injunction was granted here, Apr. 16, restraining members of the United Mine Workers from interfering with the operation of the Mound coal mine, where a strike has been in progress for some time, following the refusal of the company to recognize the union. A renewal of the rioting, in which nine men were injured, is anticipated.

Charleston—Only about 40 of the 15 mines in the Kanawha district are now working, as a result of the failure of the miners and operators to agree on a wage scale, and between 8500 and 9000 miners are on a strike. The final disagreement came when the operators refused to grant more than the agreement called for last year, while the miners demanded an unlimited check-off.

The mines closed down include all those along the Kanawha & Michigan R.R. in West Virginia. This takes in several thousand miners in Fayette County and a similar number in Kanawha County. Also, all mines are closed along the Chesapeake & Ohio in the Kanawha district, and along the branch lines, with the exception of those on the Cabin Creek branch, and the Coal River extension of the Cabin Creek branch, about 40 in number.

The Kanawha district has about 13,500 miners, so that the number now out represents approximately two-thirds. As far as it has been possible to learn, none of the mines are closed in the New River district nor in the Norfolk & Western district, but it is reported that a number of those in the northern section of the state are shut down.

Fairmont—The Consolidation Coal Co. has received an order to ship 50,000 tons of coal to Egypt to be used on the state railways. This is the second such order this company has received recently. The company is still shipping coal to England in spite of the fact that the coal strike there has been declared off. The order for Egypt will be shipped within a short time from Baltimore.

Washington

Palouse—A. E. Sever, president of the Palouse Coal & Oil Co., M. M. Waters, and C. E. Allen, who was engaged during the last winter prospecting on the land of the Palouse Coal & Oil Co., have secured a lease on ground in the vicinity of Glenwood, where indications of the existence of coal seams have recently been found. It is the intention of the lessees to prospect the new fields at once.

Personals

M. M. Bardwell, general manager of the North Jellico Coal Co., of Louisville, Ky., is at Atlantic City, recuperating from a recent illness.

Robert Lake, of Jackson, Mich., president of the Michigan-Ohio-Indiana Coal Association, was a recent visitor in Columbus, where he called upon a number of coal men.

J. C. Colsom, coal operator and president of the Indiana Operators' Association, is seeking nomination as a candidate for state senator from Vigo County to the next Indiana legislature.

C. W. Adams, vice-president of the St. Paul & Western Coal Co., a subsidiary of the Sunday Creek Coal Co., of Columbus, was recently a caller at the office of the parent company.

C. R. Leake and H. A. Turner, engineers and coal experts of Birmingham, Ala., recently made an examination of the coal-land holdings of the Cullman Coal & Coke Co., at Bremen, Alabama.

Congressman Bowman, of Pittston, Penn., has been elected vice-president of the Roden Coal Co., of Marvel, Ala., of which company his son-in-law, B. F. Roden, is president and general manager.

A. W. Fleugel, superintendent of the Island Creek Coal Co.'s docks at Duluth and Superior, recently returned from a trip to Milwaukee and other points, where he inspected various dock properties and equipment.

J. D. O'Neill, president of the United Coal Co., of Pittsburg, Penn., in company with W. S. Kuhn and W. E. Moore, large stockholders in the company, recently made a trip of inspection to the plant of the Merchants Coal Co., at Boswell, Penn., a subsidiary concern.

Chester W. O'Neill, for the past five years general sales agent of the Independent Coal & Coke Co., at Salt Lake City, has been appointed general Western sales agent for the company and will open permanent offices in San Francisco. Mr. O'Neill will be succeeded in the Utah-Idaho-Montana field by William Gorton, who hitherto has been located at the company's mines in Kenilworth, Utah.

Morris H. Bush, general superintendent of the Woodward Iron Co., has succeeded A. H. Woodward as a member of the mine casualty and mining institute committee of the Alabama Coal Operators' Association following the election of Mr. Woodward to the executive committee of the association. Benjamin F. Roden, of Marvel, Ala., has succeeded C. P. Ludwig, general superintendent of the Alabama Consolidated Coal & Coke Co., on the mine-casualty committee, on account of the withdrawal of the Alabama Consolidated Co. from the association.

Obituary

Edward Avery, aged 78, president of the Avery Coal & Mining Co., with mines in the vicinity of Marissa, Ill., died at his home in St. Louis, Apr. 10.

Charles Clark, a capitalist and one of the founders and directors of the Kansas & Texas Coal Co., died in St. Louis Apr. 18. Mr. Clark was 80 years of age.

George F. Huff, former congressman, banker, coal operator and philanthropist, of Greensburg, Penn., died at his winter residence in Washington, D. C., Apr. 18, after a lingering illness.

Mr. Huff was born July 16, 1842, at Norristown, Penn. He attended the public schools at Norristown until he was 17 years old and then the family moved to Altoona. At the latter place he entered the repair shops of the Pennsylvania R.R. and learned the trade of a car finisher. At the age of 20 years, he entered the banking house of Julian M. Lloyd & Co., Altoona. With his employer he organized a bank at Ebensburg, Cambria County. He was successful, and two years later came to Greensburg and organized a banking house, known as Lloyd, Huff & Co. Later this company was changed to the Greensburg Deposit Bank.

During the years Mr. Huff was engaged in the organization of banking houses he became interested in coal lands. He was president of the Keystone Coal & Coke Co. at the time of his death. The Keystone Coal & Coke Co. is composed of a number of coal companies, all of which originally were organized by Mr. Huff. They are the Greensburg Coal Co., Alexandria Coal Co., Mountain Coal Co., Mutual Mining and Manufacturing Co., Manor Gas & Coal Co., Madison Coal Co., Salem Coal Co., Latrobe Coal Co. and the Carbon Coal Co.

Mr. Huff organized and constructed the Southwest Pennsylvania R.R., which operated lines from Greensburg to the various coal towns in Westmoreland County. He also organized and constructed the Greensburg Electric Street Ry., the Greensburg Electric Light Co. and the Westmoreland Light and Heat Co.

Mr. Huff began his political career in 1881, when he was elected as a national delegate to the Republican convention at Chicago. In 1884 he was elected state senator and in 1888 he was elected Congressman, from the district which consisted of Westmoreland, Indiana, Armstrong and Jefferson counties and was re-elected in 1890 and 1893. In 1894 he was chosen Congressman-at-large. He was elected to Congress again in 1904, 1906 and 1908, and refused the nomination in 1910.

Mr. Huff spent his summers in Greensburg, where he owned an estate of 500 acres, and the winters in Washington. He is survived by his widow and four children.

Construction News

Brownsville, Penn.—Two hundred coke ovens are being installed at the Alicia mines near here, owned by W. H. Brown, of Pittsburg.

Willmar, Minn.—The Harmon Coal Co., of Chicago, contemplates building here a large coal-storage and distributing plant of 500,000 tons capacity.

Lonaconing, Md.—Louis Stanton, of Frostburg, Md., has purchased the property of the Georges Creek Coal Basin Co. for $20,000 and will open a new mine.

Crewe, Va.—The Southern Timber Co. is organizing to develop 10,000 acres of coal land and will install equipment for 2000 tons daily capacity; contracts not yet awarded.

Philadelphia, Penn.—The Pennsylvania R.R. Co. will construct a new coal pier at Greenwich Point. Estimated cost, $200,000. Alexander C. Shand, Philadelphia, is chief engineer.

Philadelphia, Penn.—The Philadelphia & Reading Ry. Co. plans making extensive improvements to its coal pier at Port Richmond. W. Hunter, Philadelphia, is chief engineer.

Burgettstown, Penn.—Smith & Lewis, engineers, Oliver Bldg., Pittsburg, are receiving bids for the erection of buildings for the Atlas Coal Co., Burgettstown; also for piping and other equipment.

Williamsburg, Ky.—The Proctor Coal Co. is opening new mines at Red Ash, in Whitley County, near here, and is purchasing equipment. Charles Finley, Williamsburg, is president and general manager.

Pine Hill, Ky.—The Kentucky Portland Cement & Coal Co., Munsey Bldg., Baltimore, Md., will develop 1200 acres of coal land for daily capacity of 500 tons; cement plant and coal mine equipment to cost $900,000.

Maben, Ala.—Improvements contemplated by the Sloss-Sheffield Steel & Iron Co., Birmingham, Ala., for the Bessie mine, at Maben, include two new boilers, increasing the boiler capacity 400 hp., also one air compressor.

Columbus, Ohio—The Provident Coal Co. is prepared to let contracts for construction work in connection with opening its new mine at Fairpoint. Contracts will be awarded for grading, laying tracks, mine openings and concrete construction.

Barbourville, Ky.—The Knox Coal Mining Co., of Louisville, Ky., recently incorporated with $1,000,000 capital stock, will develop 40,000 acres of coal land and will soon be open for bids for mining machinery and plant. Address company at Barbourville.

Coeburn, Va.—H. F. Whitehead, general superintendent, Virginia Iron, Coal & Coke Co., contemplates various improvements at its coal mines, doubling their capacity. It is proposed to equip the mines with new motors, erecting a steel tipple near Sexton and Thelma and to build dwellings.

Harlan, Ky.—Contracts are now being let by the Harlan Coal Co., which is developing a tract of 10,000 acres of coal lands near here. A 5-mile extension to the mines is being built by the Louisville & Nashville Ry. Machinery at the plant will be electrically operated. Kenneth Meguire, of the Snead & Meguire Coal Co., Louisville, Ky., is one of the officers of the company.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

Readjustments in market conditions have advanced to a point where the trade is again in an approximately normal condition. Some uncertainty is still felt over the anthracite situation, but it is the general belief that an agreement will be effected at an early date. The continued and apparently harmonious sittings of the wage-scale committees substantiate this belief. Bituminous mines resumed operation under curtailed capacity, Apr. 22, as was expected. Consumers are not in the market for much tonnage, as most large steam users were prepared for a 30-day suspension, and it will be two weeks before production is brought up to normal.

Wholesalers in the East are reluctant to see the market drop back to normal, as many still have considerable high-price speculative coal on hand. Comparatively little fuel is coming forward, but even these small arrivals are difficult to dispose of, as the trade is apathetic with little or no demand at full circular prices. Only about 50 per cent. of the mines in the Pittsburg district have resumed operations and production will not be up to full rated capacity for two or three weeks. West Virginia mines are supplying what little demand there is in Ohio, the trade there being quiet in every respect. Interest is now centering on the lake trade and coal fleets are preparing to sail.

Supplies in the Middle West have held out well, and the market is heavy and slow. The speculative coal, with which Chicago was swamped a few weeks ago, has been cleaned up, and there is some demand in screenings. The large tonnages, stored on the ground in anticipation of a strike, are being loaded, and a few shipments of Kentucky coals are coming in. There is a perceptible evidence of hesitancy in the trade generally.

Boston, Mass.

There has been little change in the market this week. Wholesalers are naturally reluctant to drop back, but trade in bituminous is fast settling down to an everyday basis. Cargoes from Hampton Roads are still arriving with high-priced coal and heavy demurrage charges, and in most cases where there are unsold balances they are hard to dispose of. The buyers have little interest in a receding market.

Georges Creek is being freely shipped but Pennsylvanias are getting heavy. Aside from shipments here and there to relieve those who were unable to get supplies earlier, or more likely to fill orders entered on a "panic" basis there is relatively little coal coming forward, and sales are few. On contract there is some inquiry but apparently it will be difficult to get spirit into the trade until the season is further advanced. The Virginia loading is improving rapidly, and Pocahontas and New River are quoted at near normal prices.

Freights are dull and on tonnage from Hampton Roads individual charters are matters of barter. On Long Island Sound from New York the market is off to the summer basis of 45@50 cents.

Soft coal, all-rail is coming through in large quantities, probably a clearing up of last month's mining. Speculators are having difficulty in placing this coal and since buyers are more fussy about quality than they were a month ago some low prices are heard.

Anthracite seems to be marking time. Large premiums are no longer paid, and a good volume of stock coal, especially in egg and chestnut, is being let into the market. The spring weather makes the retail demand light. Prevailing prices are:

Clearfields, f.o.b. mines	$1.20@1.40
Clearfields, f.o.b. Philadelphia	2.50@2.75
Pocahontas, New River, f.o.b. Hampton Roads	2.75@2.80

New York

The extent to which storing was carried on in anticipation of a protracted shutdown at the mines is now becoming evident by the total absence of buyers. Arrivals here so far this month have been much below normal, but there is scarcely any demand, and while prices are fairly strong, there are few transactions.

In bituminous the consumers appear to be heavily stocked, and there are few or no requests for spot coal. The railroad movement is good, water freights easier, and the arrivals steadily improving with the general resumption at the mines. Contrary to reports from West Virginia, the larger companies here say there is no labor shortage at the mines. Ordinary grades of bituminous are quoted at $2.80 f.o.b., with the better grades bringing $3.25, but there are few transactions and prices fluctuate rapidly.

It is now evident there will be no resumption at the anthracite mines by May 1, and it is generally believed it will be May 15, and possibly later, before the mines are again in operation. Work at present is confined entirely to keeping the mines unwatered; some of the larger companies in transferring coal from one colliery to another, created the erroneous rumor that they were again shipping.

There is little activity in the anthracite market at present, but it is believed the supplies are now pretty well exhausted and another week will show a decided tightening of the market. Wholesale anthracite quotations, f.o.b. New York, are as follows:

Egg	$5.00
Stove	5.50
Chestnut	5.20
Pea	3.75
Buckwheat	3.25
Rice	2.25
Barley	2.00

Philadelphia, Penn.

After almost four weeks of idleness at the mines, the anthracite industry in this city still continues in rather an apathetic condition. All dealers report that what business they are doing comes in one- and two-ton lot orders, and careful inquiry elicits the information that nearly all the dealers are in fairly good condition as regards their supply of the domestic sizes. In fact, many of them have considerably more than they want, when there are rumors that an adjustment of the difficulty between the miners and operators seems to be nearing a conclusion, and they are all hoping that the suspension will continue until they have worked off most if not all of the high-priced coal.

It almost goes without saying that there wil be some reduction in prices by the wholesale operators in the event of an early settlement of the present difficulty, but even if they do reduce the prices, it does not necessarily follow that the retailers will do the same; it might be a matter of protection to the dealers to continue present prices until their stocks of winter coal are disposed of. However, no action has as yet been taken by either one or the other, the trade as a unit waiting the final settlement of the labor controversy.

Our previous prediction that mining would not be resumed until the middle of May seems to be confirmed, as any arrangements looking to settlement during the coming week, would hardly become operative until about that time. Very little anthracite coal is coming to this market, just small odds and ends, which some of the little washeries in the

regions are able to turn out, and there is not a particularly good market for it. Dealers are looking askance at coal now at the full circular prices ruling during the winter months, and unless they are in actual need, are not disposed to buy. Steam coals, of which there is little offering, seem to fare better, but the amount is so small that it hardly deserves mention.

Pittsburg

Bituminous—The Cleveland wage scale adjustment was accepted by the miners and arrangements completed for opening the mines Monday, Apr. 22. The opening, however, was far from general, as demand for coal was so light. Large consumers had laid in stocks to carry them fully 30 days, and dealers were also fairly well stocked, so that there has not only been no pressure to obtain coal, but even an absence of the normal current demand. Probably less than one-half the capacity of the Pittsburg district has been put in operation, but production is expected to increase steadily, and to reach normal proportions within two or three weeks.

Shipments in the lake trade will begin nominally May 1, when the reduced rate of 78c., against 88c. last season, goes into effect. They will hardly be large at the start, but the season as a whole is expected to make a new record. As far as can be learned no regular selling has been done in the lake trade.

There is no demand, but producers are naming prices on a basis 7½c. higher than last year's regular or official basis, as follows: Mine-run and nut, $1.22½; ¾-in., $1.32½; 1¼-in., $1.47½; slack, 82½c. These prices constitute the quotable market at the moment, but whether they will hold is another matter. Last year's prices, based on $1.15, were shaded during the major portion of the season.

Connellsville Coke—The market is quiet, but prices are not easier as coke is scarce. We quote: prompt furnace, $2.60 @ 2.65; prompt foundry, $3; contract foundry, $2.65 @ 2.75.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Apr. 13 at 363,-289 tons, a drop of 52,000 tons. This was due to celebration of the Easter holidays by the foreign workmen. Some interests in the trade estimate that the actual decrease was larger than shown in the figures quoted, pointing out in addition that the *Courier* figures show very little greater drop in the lower Connellsville region than in the upper, whereas the lower Connellsville labor is almost entirely foreign, and in the upper region a large percentage is American. Shipments were reported at 4210 cars to Pittsburg, 5477 cars to points West and 1346 cars to points East, a total of 11,-033 cars, a decrease of 1300 cars.

Baltimore, Md.

Although some of the larger companies are still doing a fairly active business, the majority of the operators report the Baltimore coal market heavy during the past week. The demand was not near as good as in previous weeks, and, of course, prices took a further drop. A careful survey of the situation here shows that operators have, in most instances, not been able to get any better price than they obtained early in January or late last fall.

The general belief in Baltimore is that the coal trade will not show much life again until there is a more decided improvement in the business world. With the large industries running full time, the demand for coal would be increased, and as Baltimore usually holds its own in a competing market, when there is any business to compete for, local operators would probably obtain their share.

There are indications that this improvement in general business conditions will take place. The steel mills, which are large consumers of coal and coke, are operating at a greater capacity, and as steel may be said to reflect the general business condition, it would apepar that a gradual improvement in trade is taking place. Operators believe that inquiries for coal will be increased shortly, and that these inquiries will develop into deliveries.

The Consolidation Coal Co. is apparently not suffering any ill effects because of the slow market. During the past week, this well known concern forwarded 5000 tons of fuel to Egypt, for use on Egyptian Railroad. The entire contract closed in this country, calls for a delivery of about 50,000 tons. The Consolidation has numerous large orders on hand, and business is about as active now with this company as it was three or four weeks ago.

The Davis Coal & Coke Co. is now preparing to begin shipments on its contract with the Bethlehem Steel Co., and the first delivery will probably take place some time in June; the contract runs for 20 years. In order to supply the necessary fuel to the Bethlehem company, the Davis company has opened up three additional mines in the vicinity of Thomas, W. Va.

Complaint is still heard of a shortage of miners in West Virginia. It was stated in local coal circles during the week that the operators in that state could easily use 1500 additional men.

Buffalo, N. Y.

The demand for bituminous coal is light and matters are about as badly unsettled as ever, with very little prospect of any immediate change for the better. The operators are not anxious for an early resumption and are not at all pleased to find that quite a percentage of the mines in the Pittsburg district are already in operation. There is a good prospect that this new-mined coal will be on the market before there is any demand for it.

There is not much mining in the Allegheny Valley; a great part of the mines closed on the first of April and most of the others shut down on Apr. 15. The miners have been holding meetings in the valley and have issued a long list of demands, but the operators will make no further concessions than were made at the rate meeting at Cleveland last month.

There was to have been a meeting of the Allegheny Valley Operators' Association at East Brady on Apr. 19, but it was postponed. The fact is that if these mines are opened now there will be no market for the product and it is pretty close to that now. For this reason there will be no haste to get the men back to work, though there is no great expectation of saving the trade from the low prices of last year.

Buffalo operators in the tidewater trade claim it would be suicidal to make any further concessions to the miners, for they find the West Virginia product already commanding that market. If the demands of the miners were conceded, it is said that the cost of mining would be increased more than 30c. a ton.

As in recent seasons the Buffalo bituminous market will accept the prices made by the Pittsburgh Coal Co. as a basis, though it may be a hard matter to obtain them sometimes. The prices named, with freight to Buffalo added, are $2.67½ for Pittsburg select lump, $2.57½ for three-quarter, $2.47½ for mine-run and $2.10 for slack, with Connellsville coke as strong as ever and best foundry advanced to $5.

The lake fleet is preparing to sail at the end of the week, but it may be delayed by ice. There is soft coal for shipment from Erie and the Ohio ports, but nothing from Buffalo and none to be looked for at present.

There is so little demand for anthracite that dealers are getting a local supply, but shipping agents are receiving no regular amount. It now looks as though the anthracite miners would be idle for some time.

Cleveland, Ohio

The coal business continues practically at a standstill, because the miners are still out and also because of the large stocks the consumers acquired in anticipation of a strike. There is a little coal coming to Cleveland from the small mines which remained at work after the agreement expired, but this is very hard to dispose of. By the time the mines resume operations and get in full running order, it is hoped the supply will

be nearly exhausted, but nothing heavy is expected until about the first of June, at which time the stocks on hand should be used up, and the large tonnage going up the Lakes will put the market in a normal condition.

It is rumored that a large number of the Pittsburg operators will resume work on Apr. 22, and this coal will come to the Lake ports for shipments north as soon as boats are available. It is generally conceded that a very heavy tonnage will be shipped north this summer. On account of the extreme winter they have exhausted all the supplies on the docks, and will not only have to meet current demands, but will also have to restock the docks, which in the past few years they did not have to do.

Columbus, Ohio

The coal trade in Ohio during the past week has been quiet in most respects. There is not much demand for tonnage, even when all the mines have been closed down, and what demand there is has been taken care of by jobbers with West Virginia connections. Prices are ruling rather soft, which is difficult to explain, as the amount on hand is not considered very large for this season of the year.

The prospects are bright for a general resumption in all of the Ohio fields by May 1, and possibly there will be some coal mined before then. Operators are taking advantage of the suspension to place their mines in good condition, and they will be in a position to produce a large tonnage from the start.

Consumers of steam grades, who stocked up previous to Apr. 1 in fear of an extended suspension, are not renewing contracts. Many of the consumers seem to prefer taking chances on securing fuel in the open market and probably a number will not make contracts at this time.

The outlook for the future is considered good, and preparations are being made for a renewed activity in every line when the miners resume. The matter of prices is still a question of conjecture, and it is believed that quotations will rule rather low for some time. Prices which seem to prevail in Ohio fields are:

Hocking Valley	
Domestic lump	$1.50
$\frac{3}{4}$-in.	1.35
Nut	1.25
Mine-run	1.10
Nut, pea and slack	0.80
Coarse slack	0.70
Pittsburg No. 8	
$\frac{3}{4}$-in	$1.20
Mine-run	1.05
Coarse slack	0.75
Pomeroy Bend	
Domestic lump	$1.55
$\frac{3}{4}$-in	1.35
Nut	1.25
Mine-run	1.20
Nut, pea and slack	0.80
Coarse slack	0.70
Kanawha	
Domestic lump	$1.50
$\frac{3}{4}$-in	1.35
Mine-run	1.10
Slack	0.75

Indianapolis

The present indications are that the miners will not return to work Apr. 22, and possibly not on May 1, pending the final ratification of the wage scale. The operators may ask it, but the men will consent only on certain conditions, which are not likely to be accepted. The operators say they are not in need of coal at present, as the supply in storage is large enough to last until late in May at the present rate of consumption. Two years ago the men asked certain conditions, which were granted, and they worked for two months while a joint committee arranged the details of the final contract. At that time the Illinois miners were idle, and the operators had a large demand for coal from customers of the Illinois operators.

Chicago

Market conditions in Chicago have been exceedingly slow, buying being quite irregular. There was a slight increase in the demand for screenings, and indications are that all speculative coal has been disposed of.

It is expected that the buying of screenings will come first from the small users and a very fair demand is expected soon. Two of the largest concerns in the Pittsburg district have entered into competition in the Northwest with a cut price, and a sharp scramble for business is already under way. Whether the contract price on smokeless coal will hold throughout the year is a matter of speculation, and depends, dealers say, upon the turn of events in the anthracite field. No new shipments of anthracite are being received and business is dead. The market for coke is fairly steady.

Prevailing prices at Chicago are:

Sullivan County:	
Domestic lump	$2.62@2.87
Egg	2.50@2.75
Steam lump	2.17
Screenings	1.67@1.82
Springfield:	
Domestic lump	$2.57@2.82
Steam lump	2.17
Mine-run	1.97@2.07
Screenings	1.67@1.82
Clinton:	
Domestic lump	$2.52@2.77
Steam lump	2.17
Mine-run	1.97@2.07
Screenings	1.67@1.77
Pocahontas and New River:	
Mine-run	$3.15
Lump and egg	[illegible].05

Coke—Prices asked for coke are: Connellsville and Wise County, $4.85; byproduct, egg and stove, $4.95; byproduct, nut, $4.75; gas-house, $5.

Minneapolis—St. Paul

The unanimous opinion of coal men in the Twin Cities is that business in this market has never before been as quiet as at the present writing. Every branch of the coal trade seems to be in a state of hesitancy as wholesalers are still waiting for prices on which to place contracts and very little coal is coming this way for sale. Some steam users overstocked quite heavily in view of the strike and wholesalers report that a number of them are trying to back out of coal contracted for prior to Apr. 1. This has caused prices to drop considerably as some of these steam users resold coal at big losses and buyers looking for spot coal have had little trouble purchasing at low prices.

The rate case against the coal carriers in Pennsylvania before the Interstate Commerce Commission, having resulted in an order from the Commission reducing the rail rate on Youghiogheny coal from mines to Lake Erie points, 10c. per ton, has been announced in circulars issued by the Dock companies Apr. 15. Youghiogheny lump and nut sizes are quoted at $3.40 f.o.b. docks or $4.30 on track Twin Cities; dock run, $3.10 at docks or $4 at Twin Cities; Youghiogheny screenings, $2.40 dock or $3.30 track Twin Cities. Contracts are being let on Youghiogheny quite freely and wholesalers are anxiously waiting prices on which to base other coals.

The anthracite proposition is not causing very much excitement in this territory as it is generally well along in the summer before stocks arrive and by that time everything will most likely be adjusted. The retailers are the only ones who are uneasy as the consumer in the Northwestern territory has been educated to buy early during the summer and is now inquiring for prices from the retailer.

St. Louis, Mo.

The coal market in St. Louis is practically at a standstill. There are perhaps a dozen cars a week of Kentucky coal coming in, and the Illinois mines are loading the coal that was dumped on the ground previous to the shut down, whenever there is a demand for any. However, the demand is very small, and all grades of Standard coal have been practically a drug on the market.

There is still some Carterville coal being offered as low as $1.40 for lump and egg at the mines, and screenings at $1. Standard lump has been offered as low as $1.15 and screenings at 75c. At the present time there is no market in St. Louis for anything in the way of fuels.

Portland, Ore.

Coal dealers in Portland are having no trouble filling orders as it is the time of year when the demand is light. Cool weather is prevailing at this time, however, and the demand may be strengthened a little should it continue for a couple of weeks.

A topic of much interest here is the question of the policy to be followed in

regard to the coal lands of Alaska, the sentiment here being in favor of throwing them open for development. Cheaper coal here would have a tendency to stimulate many industries, and the establishment of large coal bunkers in Portland harbor is being given serious consideration by the Port of Portland Commission. The arrival of coal from foreign destinations has been very light here since the first of the year.

Production and Transportation Statistics

The Car Situation

The following table shows the surplus and shortages of cars on 169 roads on Apr. 11 last:

	Surplus	Short.	Net Surplus
Box	17,616	9,646	7,970
Flat	5,684	1,337	4,347
Coal, gond. and hopper	48,800	1,222	47,578
Other kinds	22,843	3,349	19,494
Total	94,943	15,554	79,389

Only section to report a decrease in idle cars was Montana, Wyoming and Nebraska, where a total of only 336 idle cars was reported, compared with 1551 two weeks before. Increased demand for box cars was the cause.

Some Government Contracts Pending

Washington, D. C.—Bids are asked by the Paymaster-General, U. S. N., Chief of the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., for furnishing bituminous and semi-bituminous coal, to be delivered in such quantities and at such times as may be required during the fiscal year ending June 30, 1913. The coal is to be 2240 lb. to the ton, and is to have an analysis indicating quality not lower than the following:

Moisture, "delivered coal," 3 per cent.; ash, 'dry coal," 10 per cent.; volatile matter, "dry coal," 22 per cent.; sulphur, "dry coal," 1¾ per cent.; "B. t.u.," "dry coal," not less than 14,200 per pound.

Schedule 4492, opening 10 a.m., May 14:

Class 1, 1300 tons bituminous coal, for delivery at the naval powder depot, Lake Denmark, Morris County, N. J.

Class 2, for delivery at Navy Yard, Philadelphia, Penn., 18,000 tons semi-bituminous coal.

Class 3, for delivery at the Naval Academy, Annapolis, Md., 12,000 tons bituminous coal for steaming purposes.

Class 4, for delivery at the Naval Engineering Experiment Station, near Annapolis, Md., 1500 tons bituminous coal.

Class 5, for delivery at the Naval Hospital, Washington, D. C., 2500 tons semi-bituminous coal, best quality.

Class 6, for delivery at the Navy Yard, Washington, D. C., 30,000 tons bituminous coal, to be standard grade New River, Pocahontas or Georges Creek coal, and to be crushed so that it will pass through a ring two inches in diameter.

Class 7, to be delivered at the Navy Yard, Norfolk, Va., 15,000 tons, semi-bituminous coal.

Class 8, to be delivered at the Naval Hospital, Norfolk, Va., 2500 tons semi-bituminous coal, best quality.

Class 9, to be delivered at the Naval Training Station, North Chicago, Ill., 13,500 tons bituminous coal.

Bidders are required to state: The commercial name of the coal, name of mine or mines, location of mine or mines, name or other designation of the coal bed or beds, British thermal units per pound, percentage of sulphur in "dry coal," percentage of ash in "dry coal," percentage of volatile matter in "dry coal," moisture in coal as received, and to furnish samples for test.

Ohio Coal Traffic Statement

Comparative statement of bituminous shipments over the principal Ohio railroads, for February, 1911-12, in short tons:

	1911	1912
Hocking Valley	238,060	417,176
Toledo & Ohio Central	85,282	165,118
Baltimore & Ohio	128,611	244,409
Wheeling & Lake Erie	231,328	409,966
Cleveland, Lorain & Wheeling	147,549	298,896
Zanesville & Western	94,309	121,410
Toledo Division, Pennsylvania Co.	153,504	561,675
Lake Erie, Alliance & Wheeling	99,425	141,643
Marietta, Columbus & Cleveland	1,403	13,942
Wabash Pittsburgh Terminal	7,160	4,432
Kanawha & Michigan	10,066	20,260
Total	1,196,697	2,398,927

Water Shipments to California

The following is a comparative statement of water shipments of coal and coke to California during the last three years in long tons:

Coal	1909	1910	1911
British Columbia	188,125	157,489	207,203
Australia	68,086	115,179	198,730
Great Britain	3,105	....	2,639
China	....	....	6,170
Japan	546	38,817	279
Oregon	24,125	25,293	7,439
Washington	16,940	50,342	57,298
Eastern	69,696	101,265	80,338
Total	370,623	486,385	**560,096**
Coke			
Great Britain	59,804	57,496	87,296
Australia	14,955	14,442	3,725
Washington	......	......	......
Japan	......	2,500	2,795
Total	74,759	74,438	93,816

Foreign Markets

The following is a comparative statement of the British fuel exports for the first three months of 1911-12, in tons:

	1911	1912
Anthracite	597,551	558,004
Steam	11,054,747	9,046,223
Gas	2,442,009	1,938,998
Household	368,444	299,234
Other sorts	738,601	630,613
Coke	251,671	277,123
Patented fuel	425,246	373,332
Bunker coal	4,701,509	4,051,302
Totals	20,579,778	17,174,829

British Columbia

In the East Kootenai district of British Columbia there was a falling off during the year of 1911 of 605,000 tons of coal and 40,000 tons of coke as compared with the production in 1910, and the total coal shortage for the whole province was 365,000 tons. Much loss was sustained by the various mineral smelters, due to the coal strike, and the shutting off of the coke supply.

Dutch Imports and Exports

The imports of coal into Dutch ports during 1911 showed an increase over the previous year's figures to the extent of nearly one million tons, the total being 11,344,981 tons, as against 10,347,138 tons. In 1910 a similar increase over 1909 was recorded. The exports last year amounted to 4,330,282 tons, showing an increase of 314,353 tons over the 4,015,929 tons exported in 1910.

Financial Notes

The New York Stock Exchange has listed $960,000 additional first and second, 40-year, 5% bonds of the Consolidation Coal Co., due 1950, making the total amount listed $13,960,000. New bonds are issued for additions and improvements.

The Delaware & Hudson Co.'s stock and bond holdings increased from $23,967,687 in 1910 to $27,014,189 at the close of 1911. The gain was almost wholly accounted for by the increase in Hudson Coal stock from $100,000 to $2,500,000. This served to settle the account owed by the coal company to the railroad company. The change in bonds held by the company's treasury was under $500,000.

Annual report of the International Coal and Coke Co. shows disbursements for last year as follows: Dividends, $56,073.38; maintenance, $77,554.28, and improvements, $47,029.61. The company is capitalized at $3,000,000 and owns mines in Alberta, British Columbia. Operations were suspended during eight months of last year because of strikes. It is believed the company will make a better showing during the current year.

United States District Court for northern district of Ohio, in the case of protective committee for Pittsburgh, Wheeling & Lake Erie Coal Co. 4% bondholders vs. Wheeling & Lake Erie Railroad Co. and others, held railroad company is obliged to pay off $200,000 prior lien obligations of coal company. Decision established that where corporation is organized and managed simply as adjunct to another corporation, principal corporation is liable for debts of subsidiary.

Chairman Taylor, of the Pittsburg Coal Co., gives the following details of the deals with the H. C. Frick Coke Co. and the stockholders of the Monongahela River C. C. & C. Co.: The company sold about 7000 acres of coking coal land, with improvements, at $1450 per acre to the Frick company. The final settlement will bring the proceeds up about $10,000,000. A payment of $9,561,000 has been made in H. C. Frick Coke bonds, which were sold at par, less 1 per cent. commission, and with the proceeds $8,600,000 Pittsburg Coal bonds were purchased at 110 and interest.

COAL AGE

Vol. 1 NEW YORK, MAY 4, 1912 No. 30

THE New Zealand Arbitration Court, created for the settlement of labor disputes, is the most successful body of this kind in the world. It is not bound by precedent, nor hampered by technicalities, and having legislative, as well as judicial powers, may do its best to attain fair and reasonable wages within the limits fixed by economic law.

The greatest danger connected with the just and equable distribution of wealth lies in our proneness to forget there is such a thing as market value, and, as a consequence, we often ignore the relation between what is desirable and what is possible.

As the system in New Zealand now stands, both strikes and lockouts are illegal; the piece-work system is forbidden, a minimum wage is defined for practically every trade, and the right of unionists to preference of employment is recognized. Conciliation has been declared a failure, the belief prevailing that mediation and compulsory arbitration cannot be combined. The Court reserves the right to make the contracts that exist between workmen and employers.

The aim of the Arbitration Board is intelligently set forth in the following words of one of its members: "The duty of the Court is to pronounce such an award as will enable the particular trade to be carried on, and not to impose such conditions as would make it better for the employer to close down his operations, or for the workmen to cease laboring, than to conform to them."

Compulsory arbitration has resulted in making wages more rigid, because of the difficulty met in changing the pay of one class of men without making many other changes, so as to uniformly adjust conditions in closely connected trades. There is also the inefficient or no-profit employer, who opposes the raising of wages on the ground that the slightest concession would plunge him into bankruptcy. His protests have their effect on the Arbitration Court.

Among the educated people in New Zealand, the belief prevails that any attempt to lay violent hands upon the profits of employers would put an end to all business enterprise, and thus destroy the very source from which the wealth is drawn. From such an idea, it is but a step to the position that wages are determined chiefly by economic laws, and the Court can cause only slight deviations from the valuations of the market.

The Arbitration Board has abolished "sweating," and strikes have been prevented. It is a question, however, whether the men would not have gained as much by dealing directly with their employers. It is admitted by all that wages have not increased more than the cost of living; the advance in the former over a period of 12 years has been in the ratio of 84.8 to 104.9; the cost of food increased in the ratio of 84.3 to 103.3.

Employers have been inclined to throw the blame for the high cost of production upon the Arbitration Court. Their idea is that the present method of settling disputes has added to their operation charges, not so much by fixing minimum wages as by granting limitation of apprentices, prohibition of piecework and other restrictions.

The "go easy" way of working has gained ground in New Zealand in recent years. As in other countries, the tendency of trade unionism seems to be toward a levelling down, which discourages capable men from doing their best work, and results in industrial inefficiency.

The actual results of government ownership of mines, federal competition in business, old-age pensions, and the effect of radical labor legislation in New Zealand will be discussed next week.

Fireproof Coal Washery, Panama, Ill.

By John A. Garcia *

This modern plant of 1200 tons daily capacity is of concrete and steel construction throughout. It washes all material passing through 3-in. screens at the tipple and makes five sizes of coal. Its greater efficiency, lower cost for operation and maintenance and longer life make this installation economical as compared with the more usual timber structure.

One of the main objections to coal washeries is the fact that they have a bad habit of burning down and leaving the coal company with a collection of contracts for washed coal and a lack of contracts for raw screenings, a combination sufficient in itself to reduce the revenue of the average mine below the cost of production; and this condition, although quite common in the coal business, is none the less undesirable.

The Shoal Creek Co. of Panama, Ill., was confronted last March with the problem of a burned down washery and a box full of washed coal contracts, and out of this distressing predicament it has developed a really fire-proof coal washery. This plant is simple, compact and efficient as well as fireproof and yet cost but a little more than an equivalent design of wood construction. The Allen & Garcia Co. of Chicago was given the commission for designing and superintending the construction of the washery about the middle of June. On October 3, practically 120 days later, the plant put out 400 tons of washed coal and from that day has continued to operate regularly without hitch or breakdown, a record seldom equaled in washery construction.

Completed Washery, Panama, Ill.

View Showing Steel Washed-coal Bins

The washery has an output capacity of 1200 tons per day and a storage capacity of 600 tons of raw coal and 550 tons of washed coal, a total of 1150 tons. The plant is rendered more or less independent of the continuous operation of the mine by the great capacity of its raw coal tank and the arrangement for unloading screenings which are shipped in from other mines—a part of the installation that is not yet in place.

Belt Conveyor to Washery

A 30-in. belt conveyor 174 ft. centers and built on an angle of 20½ deg. conveys the 3-in. screenings which pass through the tipple shaking screen to the top of the raw coal bin of the washery. This bin is 36 ft. in diameter and 32 ft. high, is built of steel, with a conical bottom and is equipped with a Humphrey ladder, designed to carry coal to the bottom of the bin with practically no breakage.

Coal is led from the storage bin to three Shannon jigs by a separate chute for each jig. Its flow in each chute is controlled by a lifting gate, which is operated from the revolving jig shaft and automatically feeds the proper amount of coal to each washer.

The Shannon jigs operate in a concrete tank which forms a part of one large concrete tank that is made up of several sections variously devoted to the refuse elevators, jigs and washed-coal dewatering arrangement. This tank, or series of tanks, is a massive body of concrete and although apparently expensive, is in reality the least expensive type of jig tank that can be built, because the bulk of the concrete construction greatly reduces its price per yard. Each jig has a normal capacity of 50 tons per hour so that the total jig capacity is in excess of the ordinary tonnage of the mine, which averages 2000 tons per day and makes about 50 per cent. of 3-in. screenings. The object of providing the excess jig capacity was to enable the washery to continue in operation up to the capacity of the mines should it be found necessary to shut down one jig. The refuse from the jigs, is released from the bottom of the tank by means of a gate and hand-controlled lever. It settles to the bottom of the refuse tank where it is caught by a bucket elevator, raised to a steel refuse bin and thence carried by a Koppel side-dump car to a spoil tank across the tracks.

Shaking Screens Size the Coal

Coal from the jigs flows over steel aprons to the washed-coal tank, whence it is taken up by a bucket elevator to a head chute which carries it to the sizing screens. The first operation in sizing is accomplished by means of a double-deck Parrish shaking screen, hung on 1x10-in. ash boards and run at 120 r.p.m. This shaker makes perfect separation of the following sizes:—3-in. to 2-in., or No. 1 nut; 2-in. to 1-in., or No. 2 nut; and 1-in. to ¾-in. or No. 3 nut. Everything under ¾-in. is carried by chutes to revolving screens where it is separated into No. 4 and No. 5, sizes, the No. 5 passing to the dewatering tank and thence by a perforated bucket elevator to the loading bin.

The amount of machinery employed is reduced to a minimum, the whole equipment practically resolving itself into 3 jigs, 3 elevators, a No. 6 centrifugal pump, a steam pump and the separating screens. This entire outfit is driven by one double engine, connected by rope drive to a line shaft and thence by belt and chain drives to the various units.

*Consulting engineer, McCormick Building, Chicago, Ill.

INTERIOR VIEW NEAR RAW-COAL BIN

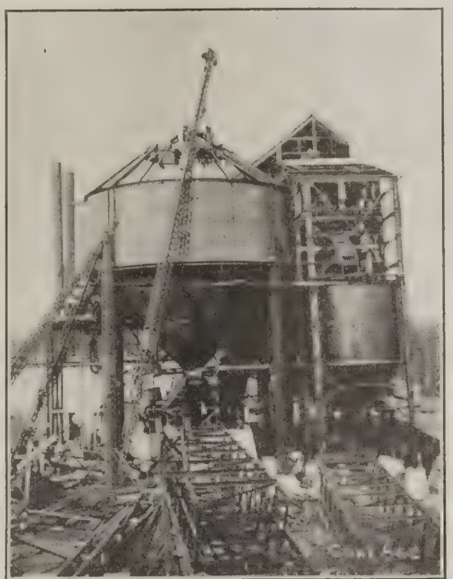
SHAKING SCREEN, SIZING NO. 3 WASHED COAL

The raw-coal conveyor is driven by rope drive from a single 40 h.p. engine in the yard near the tipple.

The five washed coal bins are each 18 ft. in diameter and 22 ft. deep, with conical bottoms. They are duplicates in design and construction and their shop and erection costs were quite low on this account. The bottoms of the bins are provided with heavy cast iron thimbles, having 15-in. openings and the flow of coal is controlled by slide gates which are moved back and forth in the direction of the loading track, by hand levers. The coal is allowed to flow into a car until it reaches the height of the bin gate and then the car is dropped slowly down the track, thereby giving each car load the neat and trim appearance that is so important to well prepared coal because the best screened coal, if loaded in a slovenly manner, at once creates a bad impression that its real merit can hardly overcome.

FIREPROOF CONSTRUCTION

The roof and upper section of the washery building and the conveyor runway are covered with No. 22 and No. 24 gage galvanized corrugated iron. The lower section of the main building is enclosed in Hy-Rib and cement. The engine room floor is of cement and the walkway of the conveyor structure is of Hy-Rib-cement construction. The hand rails are gas pipe and excepting for a few temporary walkways and hard maple stair treads there is nothing to burn in any part of the building.



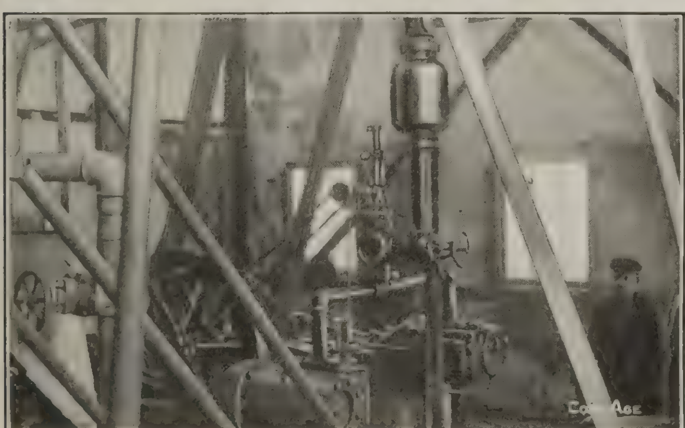
VIEW DURING CONSTRUCTION

The secret of the low first cost of the structure lies largely in the design of the structural steel, placing metal where it belongs and eliminating unnecessary members, and also in the compact arrangement of the mechanical units in order to economize space. The entire operation may be seen and controlled from either the jigs or the driving engine and it is the ambition of the coal company's management to operate the plant with two men—one at the jigs and one on the refuse car with, of course, the usual labor for spotting and loading cars.

Since the raw and washed coal tanks are protected by a rust proof paint—"Cunninghams Coal Tar"—no deterioration of steel due to sulphur in the coal is expected, although the interior of the bins will have to be repainted occasionally (a Sunday job).

The washery uses a very small quantity of water per ton of coal and after the first day's run there was practically no waste coal in the refuse. Because of the high efficiency of the machinery, the steam consumption of the driving engines is less than in the old washery which had only two-thirds the capacity of the new plant.

There are many desirable features and conveniences in the construction of this washery. A walk is built along the outside line of columns at the proper height to facilitate the loading of cars and the operation of the slide gates. There are Humphrey ladders in No. 1 and No. 2 bins which prevent the breakage of coal when flowing into the empty tank and the circular form of the bins together with their conical bottoms allows the coal to run uniformly from all sides



WASHERY ENGINE AND ROPE DRIVE

SHANNON JIGS, SHOWING MAIN SHAFTING

to the gates. Every bin will empty itself perfectly, and a car of coal can be loaded in 5 minutes.

A supply of circulating water is taken from the dewatering tank by a No. 6 centrifugal pump and, delivered to the head of all sizing screens, and also to a sluice way leading to the rotary screens. The fresh water supply is pumped directly from the reservoir, or may be taken by gravity from a storage tank placed on the hill at the proper elevation, and is delivered to the lower end of all screens, so that the various sizes of coal are clean and bright as they reach the bins.

While the machinery is arranged compactly and within an extremely small compass, every part of it is easily accessible. The conveyors are wholly within the building, and all shafting, gearing and belting are carried over platforms, easily reached by convenient stairways and walks. There is a walk entirely around the screens, and an outside stairway leading from the screening house to the top of the raw-coal bin. This latter can also be reached from the tipple by a walk alongside of the conveyor. The whole structure is notable for its extreme rigidity and strength.

An Economical Installation

Screenings in the Montgomery County, Illinois, field contain a large percentage of foreign substances, due to the sulphur streaks, blue band and bone coal found in the seam and to the methods of mining and loading, and it is expected that this type of washery will almost revolutionize coal mining practice in this field.

The greater average revenue which can be obtained from an installation of this kind, after deducting the cost of washing and the interest on the cost of construction, makes for an ideal investment. In addition, a wider range of sizes and an improved quality of product are secured, and therefore, a wider market and better running time, which, of course, also make for cheaper coal.

The structural steel for this installation was furnished and erected by the Wisconsin Bridge & Iron Co., Milwaukee, Wis.; the machinery was supplied by the Link-Belt Co., Chicago, and the entire plant designed and superintended by the Allen & Garcia Co., Engineers, Chicago.

A Mammoth Seam in Colorado

By Benedict Shubart*

A description of the preliminary development of an unusually large Western seam. The customary tipple has been replaced by a system in which the coal that is to be sized and loaded into railroad cars, is dumped at the railroad-track level, and then elevated to the top of the screens by means of an inclined conveyor.

*Boston Building, Denver, Colo.

Commencing Dec. 15, 1911, coal was shipped from one of the most remarkable mines in Colorado. The recently completed Laramie, Hahn's Peak & Pacific Railroad, starting at Laramie, Wyo., and running southwest to the North Park coal field in Jackson County, Colo., has opened up to market the immense seams of coal long known to exist in that field.

The Coal

During the last two years, E. R. Miller, Stewart Kennedy, and others, have been acquiring coal land and doing prospecting work in this section. For many years past the ranchers have driven from 75 miles around to this seam, digging the coal from an open pit, and hauling it to their ranches in wagons. But the full thickness of the seams was never developed until these men thoroughly prospected the field with a Loomis "Hollow-rod" drill, proving a top seam 65 ft. thick with 2 ft. of clay and 10 ft. of bottom coal, and three lower seams, 30 ft., 12 ft. and 18 ft. thick respectively.

The Northern Colorado Coal Co., incorporated under Wyoming laws, was organized and has acquired 4000 acres of coal land and a considerable amount of ranch land for the purpose of raising supplies and forage.

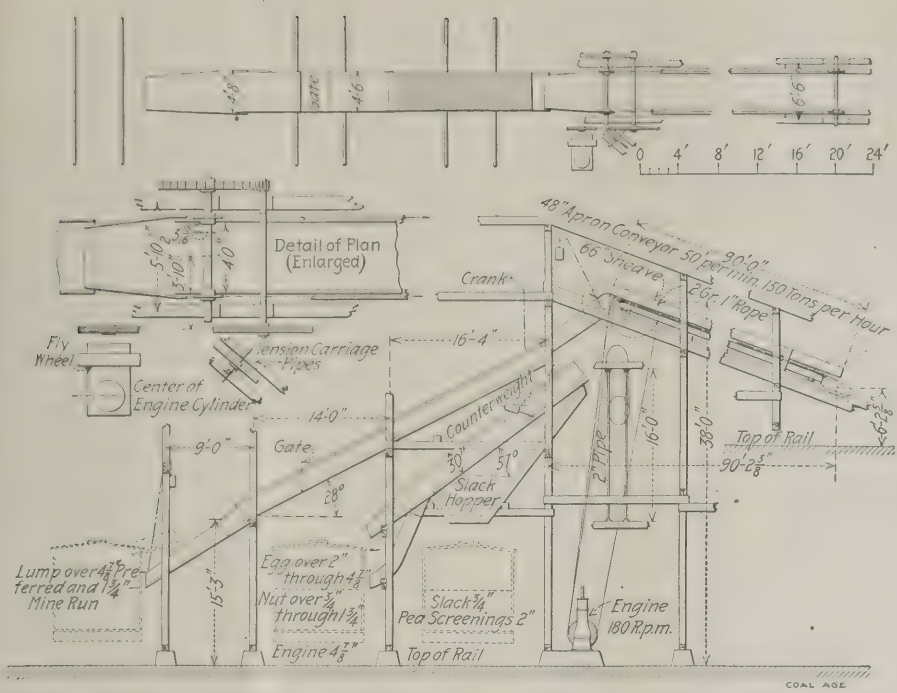
The immensity of the seam is shown in the accompanying halftones. At present coal is still being taken from the open cut, about two acres, 35 ft. deep being exposed, but a slope is now being driven down the 16° pitch of the seam, and a 12x24-ft., three-compartment shaft is also being sunk which will tap the seam at about 112 ft. The mine will be opened up on the room-and-pillar system, the 10-ft. bottom coal being taken out first, and the balance being mined when the room is brought back.

The coal is semibituminous, very similar in texture and appearance to the Rock Springs No. 1 coal. It is black, very blocky, and comparatively smokeless. The composition of the mammoth vein coal is as follows:

Analysis of the Coal

	Per Cent.
Moisture	8.5
Volatile matter	43.2
Fixed carbon	44.2
Ash	4.1
	100.0
Sulphur	0.50
B.t.u.	11,000

Stripping Operations of the Northern Colorado Coal Co., at Coalmont, Colo.



The Northern Colorado Coal Co.'s Tipple, Showing Apron Conveyor

The town of Coalmont, where the mine is situated, lies southwest of Laramie, 111 miles by rail. The very mountainous nature of the country made it impossible to construct a railroad from Denver or to branch off from the Moffat Road. The only practical outlet found was to the northeast and the rugged nature of the country made it necessary to select a very circuitous route for the railroad. However, by careful work, maximum grades of 1 per cent. out and 1.9 per cent. in have been obtained.

The Tipple

The tipple equipment was designed by Stewart Kennedy, general superintendent of the company, and follows the lines which he has successfully used in the Sheridan, Wyo., fields. The pit cars will not be taken up the usual high trestle but will be dumped into a hopper set on the ground, as shown in the accompanying drawing of the tipple. The usual crossover dump, with car haul for returning the empties, will be used and the mine-run coal will be automatically taken from the hopper and elevated to the screens by means of a Link-Belt corrugated apron conveyor, which acts both as a feeder and conveyor. This will distribute the coal evenly to a gravity screen which will make the following grades of coal: Lump, egg, nut, egg-run (for locomotive use), mine-run, and slack. This system of screens is very flexible and efficient. When the mine is developed to the full capacity of 1500 tons per day, an elevator and rotary screen will be installed for re-screening, provision having been made in the plans for this. The entire tipple equipment was furnished by the Link-Belt Co. of Chicago.

The power plant consists of two, 16-ft. by 66-in., Nagle, horizontal, tubular boilers, 110-lb. steam pressure, which furnish steam for the auxiliaries and for a 100-hp. Ottumwa Iron Works hoist. The present plant is being installed merely as the nucleus of a more complete plant. All machinery is being installed in a permanent manner so that the proper additions can be made later to take care of the increased capacity. Electrical equipment will not be installed for the present.

Another View of the Stripping Operations, at Coalmont, Colo.

President and general manager, E. R. Miller, with offices at Laramie will take care of the general Western sales. The Central Western trade will be cared for by the Havens, White Coal Co., of Omaha who will cover the territory of Nebraska, Iowa and Kansas. Complete traffic arrangements have been made between the Union Pacific Railroad and the Laramie, Hahn's Peak & Pacific Railroad, and the coal will be shipped out under the trade name of "Mammoth Vein Smokeless Coal."

Coal Loading Booms at Annabelle Mine

Special forms of coal-handling machinery, designed to avoid breakage, are coming more and more into prominence. Despite improvements in the various devices for burning fine coal, the demand of the consumer is imperatively for large sizes, and because of the difference in price between large and small sizes, nearly all breakage in handling the coal results in a direct loss to the producer. With these considerations in mind, the engineers of the Four States Coal & Coke Co. have introduced a number of improvements over usual practice in the design of the tipple at the Annabelle mine, near Worthington, W. Va.

Perhaps the most interesting of these is the device for loading lump coal into cars, which is illustrated on the front cover of this issue. At the Annabelle tipple, all the lump coal passes over two steel-band picking tables, 6 ft. wide and having about 40 ft. of clear picking space. The loading ends, or booms, of these picking tables are, for a length of 26 ft., free to move in a vertical plane. They are continuous with the picking tables proper, being connected thereto by a trunnion. At the free ends are the tail sprockets of the picking bands, carried in trussed steel frames, supported by ropes from an overhead electric hoist. Attached to each boom is a short chute, which tapers to 30 in. in width. This concentrates the stream of coal, so that the car is neatly topped out.

The device is controlled by the loader, who stands on the picking floor of the tipple, immediately above the cars that are being filled. He thus has a full view of the operation, through large railed-off openings in the floor, and has the controllers of both loading-boom hoists convenient to his hand. Levers, operating the clutches which drive the picking bands, and electric signals to the mine-car dumps are also within his reach. The loader controls the movement of the railroad cars by means of a car retarder. This device consists essentially of a band brake with its lever, and a drum, on which is wound a wire rope that passes

over pulleys uptrack from the tipple and is hooked to the car. The grade of the track under the tipple is 2 per cent., so that this rope is always taut and the moving car absolutely under control.

On beginning to load, the empty car is brought into position, and the boom lowered until the chute is practically on the bottom of the car. The picking band is then started and the coal is carried on this to the end of the boom. It will be seen that there is thus practically no drop at all in loading the coal into the bottom of the car. As the car fills up, the loader gradually raises the boom without stopping the flow of the coal until he has one end of the car filled to the top. He then slowly drops the car so that the coal is always delivered to the edge of the pile already formed. When the car is full, he stops the picking band, while a new car is being dropped down. If it is necessary to stop the band for a considerable time, the loader signals to the dumper to cease dumping, in order to prevent an accumulation of coal on any part of the tipple apparatus.

The tipple is equipped with two cross-over dumps, having steam pull-backs, two lump-coal shaking screens, two picking bands, two fine-coal elevators and conveyors, and two revolving fine-coal screens. It is thus seen that the entire tipple apparatus is in duplicate, and either half can be operated independently of the other.

Particular attention has been paid to bypass arrangements, and the duplication of parts. All bearings, gears, etc., are cast steel, so that the risk of breakdown has been reduced to a minimum. The capacity of the tipple is 3000 tons per day.

The Coal Fields of Western Canada

By E. Jacobs*

An interesting and comprehensive compilation of various data on the coal industry in Western Canada. The geology and relative commercial importance of the different fields are briefly sketched. The industry as a whole is likened to the Pittsburg field in the United States and an equally bright future is predicted for it.

In the course of the fourth of his series of lectures on coal to the fourth year class in geology at McGill University, Montreal, Quebec, in 1910, D. B. Dowling, of the Geological Survey of Canada, gave some interesting information relative to coal in Western Canada, as well as in other parts of the Dominion.

The preliminary statements attributed to Mr. Dowling in a report of the lecture published in a Montreal newspaper include the following:

Canada is destined to become one of the greatest coal-producing countries in the world. The deposits of coal now known to exist in Canada would supply the needs of the whole civilized world for the next 170 years. The coal deposits of Canada compare favorably with those of the greatest coal-mining countries in the world as to quality, quantity, and accessibility for mining purposes. The Welsh coal is supposed to be the best in the world, but in the Rocky Mountains of Western Canada there is coal which compares favorably with the best Welsh.

The production of coal in Canada has increased greatly during recent years. In 1902 it was only about 7 million tons, but during the three years 1907-1909, between 10 and 11 million tons a year were mined. There is as yet no reason to suppose that this production will seriously affect the future coal supply of the Dominion, when the extent of the coal fields and the available supply of coal are taken into consideration.

Workable Coal in Canada

New areas of coal-bearing formations are being found in the partly explored Canadian West. There are large areas that are fairly well known, in which it may be expected that coal will be mined. Parts of these are not yet within reach of transportation facilities, or require deep mining to recover the coal.

An estimate of the workable coal in Canada* gives a total of 173,736 millions of tons, as follows, in millions of tons:

Anthracite	470
Bituminous	71,391
Sub-bituminous	87,490
Lignite	12,385
	173,736

It is of interest to note in this connection that approximate estimates give Great Britain's supply of bituminous coal at 60,000 million tons and Germany's at 52,000 million tons.

Occurrence and Analyses

The following is an excerpt from a paper on "The Mineral Industries of Canada," contributed to the Internationaler Kongress, Dusseldorf, 1910, by H. Mortimer-Lamb, secretary of the Canadian Mining Institute:

The extensive coal areas of Canada are found in the Provinces of Nova Scotia and New Brunswick, in the East, and in the Saskatchewan, Alberta, British Columbia, and the Yukon Territory, in the West. The Eastern measures occur in the Carboniferous formation, while those of Central and Western Canada are found in the Cretaceous and Tertiary. The Eastern coal is entirely bituminous, the Central chiefly lignite, while in Western Alberta, British Columbia, and the Yukon the coal ranges in character from a high-grade lignite to anthracite. Lignites of still more recent age occur in Ontario.

Average analyses of Canadian coals from the respective areas are shown in the following table, compiled for the writer by Edgar Standfield, M. Sc., of McGill University, Montreal:

Coal Field	Moisture Left in Air Dried Sample	Fixed Carbon	Volatile Matter	Ash	Sulphur in Dry Coal
Nova Scotia					
Sydney	2.6	57	36	7	2.4
Pictou	1.7	57	30	13	1.2
Manitoba					
Souris	18.1	45	44	11	0.6
Alberta					
Edmonton	19.0	50	40	10	0.4
Cascade	0.7	72	15	13	0.7
Frank-Blairmore	0.8	57	26	17	0.6
British Columbia					
Crow's Nest	0.9	64	25	11	0.5
Nanaimo-Comox	1.5	51	36	11	0.9

Manitoba and Saskatchewan

In an official report,* published in 1909, D. B. Dowling gives "a concise statement of the area and probable contents of the various coal fields of the middle portion of Canada." Regarding the location and area of these fields, he says:

In Manitoba, the coal-bearing rocks occupy a small area in the southern part, underlying an elevated portion called Turtle Mountain. With our present knowledge we can define an area of about 48 square miles near the western end of this hill as being available for mining.

The Saskatchewan areas lie principally in the southern part, and are

*Secretary, Western Branch of the Canadian Mining Institute, P. O. Box 645, Victoria, British Columbia.

*See Quarterly Bulletin of the Canadian Mining Institute, No. 15, June, 1911, p. 107.

*"The Coal Fields of Manitoba, Saskatchewan, Alberta, and Eastern British Columbia," by D. B. Dowling, Canada Department of Mines, Geological Survey Branch, No. 1035.

being mined on the Souris River. The elevation known as the Coteau is also composed of coal-bearing rocks, which continue westward in the Wood Mountains and Cypress Hills. This area, though not well prospected, contains possibly 4000 square miles within which coal may be found.

The Province of Alberta is liberally supplied with coal areas. The elevation of the coal formations subjected them to greater denudation than the harder rocks beneath; consequently little of this material is left; but in the wider valleys remnants are still found. These, from the superior quality and the amount of coal, form very valuable coal fields. East of the foothill area lies a great extent of coal-bearing rocks which are comparatively undisturbed. The coal in this region is well suited for domestic use, and as it is within the settlement belt, where wood is scarce, a demand for it is assured.

Another coal formation occupies the southwestern border of the province, with an area of 5000 square miles; the seams in this are of more value in the southern portion than farther north, or east. The principal mines of this area are to be found near Lethbridge.

Coal in Alberta

The coal areas of this province occur in three divisions of the Cretaneous. The lowest is exposed in long narrow belts in the outer ranges of the Rocky Mountains and the foothills. These areas, besides providing the best coal, are important in that they contain many thick seams, thus ensuring a large supply of valuable coal. The middle division, found occasionally in the foothills, is better known as the Lethbridge formation and is exposed over a large area in eastern Alberta; it furnishes a coal that grades from bituminous to subbituminous and lignite. The higher coal-bearing beds are well exposed in central Alberta. Those on the western edge of the area contain seams approaching bituminous, but in the eastern part the coal is sub-bituminous.

Mr. Dowling's latest published estimate gives for the province of Alberta a total coal-bearing area of 29,608 square miles, with an aggregate coal content of: Anthracite, 400 million tons; bituminous, 30,250 million tons; and sub-bituminous, 79,000 million tons; in all, 109,650 million tons.

Coal in Western Canada

The following excerpt from "Geology and Economic Minerals of Canada,"* gives an idea of the extent and importance of the coal fields of western Canada.

The coal produced in the Cordilleran region of Canada is almost entirely bituminous, and by far the greater part is of Cretaceous age. Coals of Tertiary age are known at a number of localities, as in the Nicola Valley, and near Princeton, Similkameen. The Tertiary coals are lignites, and sometimes form thick seams, as in the case of the Princeton area, where an 18-ft. seam outcrops on the banks of the Similkameen River.

On Vancouver Island, the coal seams occur in the upper part of the Cretaceous. Coal mining is concentrated in two areas on the east coast of the island, known as the Comox, and the Nanaimo coal fields. The Comox has an estimated area of about 300 square miles. At one mine, within a vertical section of 122 ft., there are 10 seams, with an aggregate thickness of about 29 ft., the thickest seam measuring 10 ft. In the Nanaimo field, two seams, one varying in thickness from 5 to 20 ft., and the other from 3 to 5 ft., are being mined. The coals are all bituminous.

In the Rocky Mountains and the foothills, the Cretaceous coal measures occur as basins among the folded and faulted Palæozoic and Mesozoic strata. The basins, generally stretching northwestward and southeastward, and sometimes for very long distances, are known to occur at intervals from the International Boundary to the Athabaska River, a distance of more than 200 miles. The coals within the Rocky Mountains are bituminous varieties, in places passing to anthracite, as at Bankhead and the anthracite mines in the Bow Valley. Eastwards, in the foothills, as the plains are approached and the regions of disturbance left behind, the lignite coals of the higher members of the Cretaceous are gradually encountered.

Within the mountains and the adjacent foothills, there are three coal horizons. The lowest occurs within the Kootenai formation belonging to the base of the Cretaceous, possibly the summit of the Jurassic. The seams of the Elk River and Crow's Nest basins lie within this horizon. The next group of productive measures is the Belly River, situated near the top of the upper Cretaceous column. The highest group of the coal measures lies in the Edmonton of early Tertiary age.

In Conclusion

Nothing like a review or summary of the coal resources of Western Canada will be attempted, but as an example of the view taken of the prospective importance of these Northwestern coal fields, only an excerpt will be made from an official comment of William Fleet Robertson, Provincial Mineralogist for British Columbia, contained in his annual report for 1909.* Dealing only with the Rocky Mountain coal fields, he wrote in part:

The Rocky Mountain coal fields, lying on either flank of the main range of the Rocky Mountains, respectively in the provinces of British Columbia and Alberta, are undoubtedly the most extensive coal deposits in Canada, and, what is more important from a commercial point of view, are the only large coal fields of first-class coal at present known on the Pacific slope, between Alaska and Mexico.

While it has been a matter of common knowledge in British Columbia that these deposits were large, it is questioned if more than a few people recognized their wonderful extent, or the enormous influence they must have on the future of the country. What this influence must be can best be demonstrated by an illustration of what the coal deposits of Pennsylvania have done for that state. They have made it probably the greatest manufacturing state of the Union—and the condition of Western Canada today is that of the Eastern United States 50 years ago, except that we may look forward to a more rapid development, due to the more general development of the rest of the continent and the improved transportation and other facilities now available.

It seems, therefore, that eastern British Columbia is destined to be, from the possession of its coal fields alone, the Pennsylvania of the Pacific slope, and that at no distant date.

Kentucky Mining Institute

The next meeting of the Kentucky Mining Institute will be held at Lexington on Monday, June 10. At the December meeting, a committee on program and entertainment was appointed; the members of this committee are Messrs. Hywel Davies, P. V. Cole and H. D. Easton (chairman). The Executive Committee cast a vote by mail and selected Lexington as the place to hold the June meeting. The institute won much credit by the excellent papers presented at the December meeting although the attendance was not large. These papers have been published in various mining journals and they are to be included with the papers read at the June meeting, in the transactions of the Institute. It is probable that the June meeting will last two or three days and that a side-trip will be arranged.

While it has been thought that electricity has been a contributing cause to some mine explosions, not a single explosion in American mines has yet been traced directly to its use.

Shaft and Slope Construction, 201 Mine

By R. G. Johnson*

The construction of a concrete-lined shaft and slope in southwestern Virginia. The character of the surface was such as to make slope sinking extremely difficult. All concrete was placed by gravity chutes or by special chute cars. Details of designs and of contractor's plant.

In May of last year, the Clinchfield Coal Corporation started the construction of a large coal-mining plant on a comparatively new portion of its property, in Russell County, Virginia. The operation is located near Slemp, on the Carolina, Clinchfield & Ohio Ry., about five miles from, and in direct connection with, the Clinch Valley Branch of the Norfolk & Western Ry., at Keiser. A contract was awarded for the sinking of a large concrete-lined hoisting shaft, and a slope with an air-shaft connection, but the power plant, tipple and other surface equipment were constructed by the company itself, under the direction of consulting engineers.

Lower Banner Coal Seam

Since the opening up of the coal measures in this particular section of the state is of quite recent date, a brief description of the coal may be of interest. The seam to which the shafts were sunk is known as the Lower Banner, and called locally the No. 4 vein. Geologically, it is near the bottom of the Norton formation, which overlies the Lee conglomerate. This is a continuation of the Pottsville conglomerate, which, as is well known, extends from the Pennsylvania anthracite field through the Virginias, and thence south through Kentucky and Tennessee into Alabama.

The Clinchfield corporation has proved by extensive drilling the existence of a good many thousand acres of the Lower Banner seam. The coal, an analysis of which is given below, is high in heat units, and compares well in calorific power with the best New River and Pocahontas output.

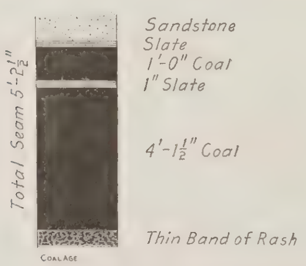

Fig. 1. Typical Section, Lower Banner Seam

ANALYSIS

	Per cent.
Moisture	0.70
Volatile matter	24.97
Fixed carbon	67.60
Ash	6.73
Sulphur	0.53

The columnar section, Fig. 1, taken in the heart of the Clinchfield company's field, shows what has proved to be an average thickness of the seam. Continuous low-vein mining machines are installed. These cut in a band of rash beneath the coal, the rash being loaded separately for consumption at the power plant, the high stack of which aids in the economical use of this fuel.

*Engineer with the Dravo Contracting Co., Pittsburg, Penn.

Modern Concrete-lined Shaft

In planning the shaft and slope, the most modern economical practice was followed. The shaft is concrete lined throughout and fitted with yellow-pine timber buntons and guides. Although reinforced-concrete and all-steel buntons have been placed in some of the latest concrete-lined shafts, the advisability of their adoption is a mooted question. Were it not for its excessively high cost, the reinforced-concrete bunton would be ideal. In using the all-steel bunton, a heavy section is required, because it is necessary not only to figure against a possible pressure of the ribs at the sides of the shaft, but also to provide against the corrosive action of the mine air and of water dripping from the cages, which is a far bigger factor than pressure, especially in sandstone country. A reinforced-

COAL AGE

Fig. 2. Construction Record, Progress of Sinking and Concreting

concrete bunton and a steel bunton of fairly heavy section each cost about three times as much as timber in place in the shaft.

The policy of a company largely determines the character of the construction adopted, and plans for a shaft that will serve the purpose can be made to fit any reasonable budget, the only question being the degree of efficiency and the length of time the figured efficiency will continue. If the company knows its coal seam, and believes there is economy in so called "model plants," shafts can be

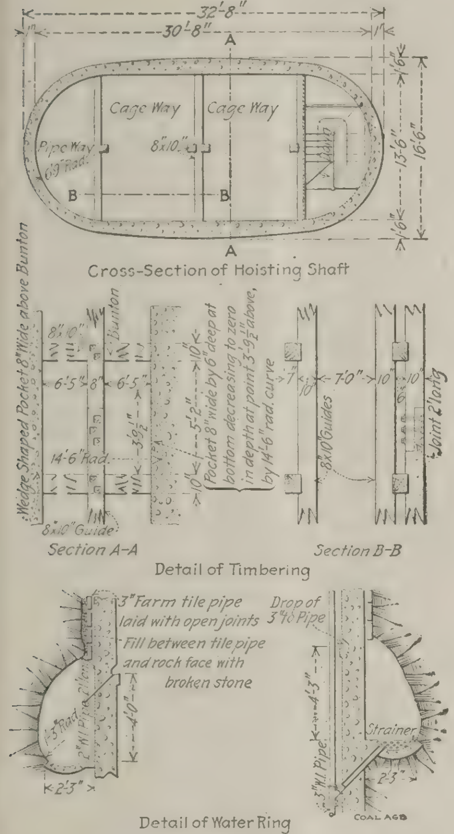

Fig. 3. Details of Shaft Construction

made of watertight and fireproof construction that will last forever. The Clinchfield Coal Corporation maintained, and wisely, too, that the vital parts of their plant should be of the best construction, while certain other elements, which could be replaced readily and economically, might be of a temporary and less costly nature.

In sinking the shaft, no unusual features were encountered, except possibly the badly broken-up rock structure. This condition, while uncommon in western Pennsylvania and upper West Virginia, is not unfamiliar, however, to rock men in southwestern Virginia and in the lower sections of West Virginia. Drilling in crevicy, hard rock is difficult, especially on inclined holes, as the points of the steel bound when striking the bottom of a crevice at an angle.

Sinking Progress

While little water was struck at the start of the rock sinking, the amount rapidly increased as work progressed, and at a depth of 60 ft. the shaft was making about 180 gal. per min. However, this was very cordially welcomed by the coal company as a source of supply for the power-plant condensers, and its later almost complete disappearance was as sadly mourned. The coal was reached in good time, as reference to the construction record, Fig. 2, will show, something more than 100 ft. having been sunk in a little over a month. As soon as the coal was taken out, excavations were made for arches on both sides of the hoistways.

On the floor of the sump, a layer of concrete 6 in. thick was placed on a thin bed of broken stone, to form a level foundation for starting the lining concrete. The recesses for the arches in the concrete lining were sunk 10 ft. below the bottom of the coal, to allow for lowering the shaft-bottom entries, if necessary, in order to provide for the proper grades to the cages. The arches were carried only 5 ft. back from the face of the lining, and here again was shown the wise application of the company's plan to build foundations at present for future additions, which may be made as time proves more clearly the character of the coal.

Water Ring and Drains

Just above the coal, a ring was formed back of the shaft lining, to catch the water from 3-in. tile drains placed vertically between the concrete and the rock rib. These lines of tile were laid with loose joints and completely surrounded by broken stone. The shaft was well drained; but with the knowledge gained from the recent successful applications of the pneumatic grouting process for sealing the water-bearing seams encountered in shaft sinking, different drainage methods would now be employed and the flow of water entirely shut off by cementing the crevices. This process, recently described in the Feb. 24 issue of Coal Age, has since been used repeatedly in connection with shafts sunk in New York City for the city tunnel of the Catskill Aqueduct, and its complete success has attracted widespread attention among engineers and mine operators.

The concrete in the lining of the shaft was mixed in the proportions of 1-2-4, and that in the coping of the shaft in the proportions of 1-2½-5. The lining was designed to be 12 in. in thickness at the ends and 18 in. at the sides. It is, of course, impossible to drill and shoot rock to accurate lines, so that a great deal more concrete was required to be placed than the drawings called for. Between the rock rib and the exterior of the lining, as determined by the 12- and 18-in. wall thicknesses, one-man stones were placed in the concrete. The bulk of the concrete was carried to its place in the forms by means of chutes hung in zigzag fashion down the shaft. This

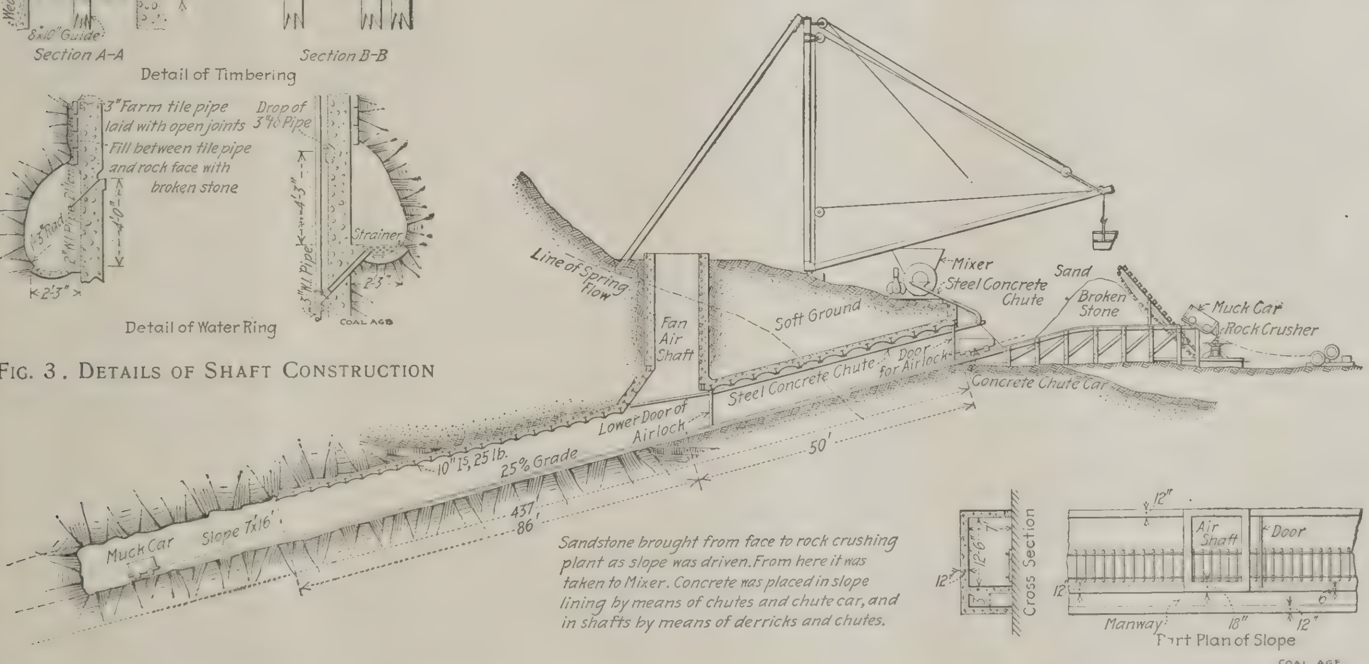

Fig. 4. Details of Slope Construction and Contractor's Plant

proved to be a decidedly quicker method than using buckets.

Slope Construction

The slope, put down in conjunction with this shaft, was located ideally, as far as outside track layout was concerned, but the excavation through the earth surface proved very difficult. The soil in this region is largely a yellow clay mixed with gravel and small boulders, and numerous springs, coupled with the rains, have caused the top soil to slide over the rock surface on many hillsides. Railroad cuts and roads in this section are often obstructed by such slides, and with little warning. It was evident after the slope had been started and was in only 20 ft., that a similar condition had here been encountered. The ground became heavy and difficult to tunnel and to timber by ordinary methods.

Timber centers were shortened and forepoling, such as is used in very soft ground, was found necessary. Although a possible 20 ft. of surface had been expected from the appearance of an outcrop of the rock strata not far above the slope mouth, actual working found the contractors tunneling for over 100 ft. before they reached a full rock section. The source of the trouble appeared when a particularly wet piece of ground was reached, and was followed by perfectly dry strata. A thick layer of sand, gravel and boulders had slid over a thicker stratum of clay, the spring water from the rocks above acting as a lubricant.

Timbering was required for a distance of 36 ft. beyond the earth section to prevent the caving of the thin rock overburden. Beyond this point, 136 ft. from the portal, to the bottom of the slope, the hard sandstone required no support of any kind over its entire 16 ft. of width, although the concrete partition wall put in later serves as such. The soft sliding nature of the earth section necessitated a change of plans for its permanent support, and a design, specifying 10-in. I-beams with concrete arches between them, was selected.

Concrete Placed by Gravity

The placing of concrete in the slope was done, for the most part, by means of long steel chutes. The lower sections of the 12-in. concrete partition wall and a portion of the roof arches were concreted by the use of a specially shaped car, having a chute attached. This method was entirely successful, the car being filled from the mixer at the slope portal and run down to a level just above the wall form, where a small portable chute was attached and the concrete run by gravity to place. The side-wall forms were filled with absolutely no handling of the concrete from the mixer, and the labor of tamping, and attaching the chutes to each carload, represented the only hand work done on any of the concrete at the slope bottom, 437 ft. from the portal and mixer. The only hand labor required in connection with transportating the concrete was that found necessary to insure a good job in placing the material in some of the roof arches, where the caps of the temporary timber bents were so close to the I-beams that there was not room for the chutes.

The original plans called for a Y-branch fanway, leaving the slope 70 ft. from the portal. The expense and hazard of tunneling and permanently supporting the soft ground for the main slope led the engineers to change their plans, omitting the Y-branch and constructing an air shaft over and into the slope about 50 ft. from the mouth. The concrete lining of this shaft was heavily reinforced with I-beams to resist the overturning moment of the hillside pressure, and by grading the surface at the shaft coping, an admirable fan site was prepared. An air lock was then placed in the slope, between the portal and the air shaft, for admitting supply cars to the mine, the whole making a unique and efficient arrangement.

Modern Power Plant

The central power plant for the mines, in the Dumps Creek division of the Clinchfield Corporation, is worthy of note, as it is without doubt one of the best in the bituminous coal fields. It is located near the shafts above described, on the Hurricane Fork of one of the main tributaries of the Clinch River. The present equipment comprises two 1000-kw., 6000-volt, 3-phase, 60-cycle Westinghouse generators, driven by Parsons turbines. An additional 2000-kw. machine has been purchased, and the building is so constructed that other units can be installed as needed.

The hot water from the Westinghouse surface condensers is pumped to cooling towers, situated over a reservoir, which has been formed by damming the stream about 200 ft. from the power house. Steam is supplied by three 400-hp. Wickes boilers with Cochrane feed-water heating system, all the boiler-room elements being placed with the future conditions in mind. Current for the haulage system of the No. 201 mine, of which the shafts are a part, is furnished by a 300-kw., 275-volt, direct-current generator, driven by a synchronous motor.

The shafts and slope were designed by D. R. Beeson, under the direction of H. M. Waite, then vice-president and chief engineer, and Carel Robinson, division superintendent. The construction work was done by the Dravo Contracting Co., of Pittsburg.

The United States imported 172,716 short tons of coke during the year 1910 and exported 984,562 tons during the same period.

Calcium Chloride

Among the methods for creating immunity from coal dust explosions is the use of calcium chloride. This chemical compound has the power of absorbing water, and under favorable circumstances such as are usually found in a mine, 100 lb. of the material will take up 115 lb. of water. Even in face of a strong sun, the salt will take up 50 to 60 lb. of moisture. It is easy to see, therefore, that in any ordinary mine, it will retain enough water to keep the places sprinkled with it in a perpetually damp and coherent condition. Dampness and coherency are the two requirements of a harmless coal dust.

A roadway well treated by the chloride should be as immune from an explosion as a dustless zone. But such a dustfree working is created at considerable expense and does not have the power of self-maintenance. The condition has to be continually renewed at the expenditure of no little labor. While on the other hand, the chloride moistens all the dust which falls and renders it innocuous, and does not need frequent attention.

Its principal sale today is as a road-binder. This use exhibits well its power of creating an agglomerate mass out of a collection of separate solids, and this would appear to be an argument for its use in mines where the roads are often in bad condition for traveling.

Pure calcium chloride is white and odorless. It is the presence of hypochlorite of lime which causes the pungent odor of the impure variety. The strong smell of the impure salt is due to the continuous liberation of chlorine from the decomposition of the hypochlorite.

Calcium chloride does not injure the hoofs of mules. It may be applied either in solution or as a solid. When used dry, it will soon obtain the necessary moisture from the air. It is reported that the Bureau of Mines is about to make an examination of the chloride to ascertain its desirability as a means of checking the extension of mine explosions.

Byproduct Coke Ovens

On p. 808 of Coal Age, No. 25 is given a list of byproduct coke ovens operating in the United States, as of Jan. 1, 1910. The following additions will bring it up to Jan. 1, 1911 (cf. *Journ. Ind. and Eng. Chem.*, March, 1912). *Koppers*: Woodward Iron Co., Woodward, Ala.; Tenn. C. I. & R.R. Co., Corey, Ala. *Rothberg*: Cleveland Furnace Co., Cleveland, Ohio; Lackawanna Iron & Steel Co., Lebanon, Penn. *Didier*: Lehigh Coke Co., South Bethlehem, Penn.

Without the dreamer industry would not exist, and without the worker it could not. Moral: Be both.

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Fire Fighting in India

The following remarks on mine fires in India are taken from the *Transactions* of the Mining and Geological Institute of India. They are contained in an article written by W. H. Pickering and R. R. Simpson. They state that the Koithi and Sibpur beds in the Raniganj coal field measure 14 ft. and 18 ft. respectively. Owing to this great thickness, to the readiness with which the coal burns and to the great strength of the roof, the problems presented by mine fires are unusually difficult.

"In considering the inherent dangers of coal mining in India, it is necessary to clear our minds of any prejudices due to experience in other countries. The conditions are very different from those which obtain in other coal fields. To be specific, the fire dangers are markedly different. The extraordinarily strong roof over the coal allows wide galleries to be driven to the full height of the thick beds, and the practice has been to cut up large coal areas into pillars by such intersecting galleries.

Air Blasts

If the pillars crush or are burned out, the roof will not fall until a large area is left unsupported. Thus when the fall does take place, an air-blast is inevitable. Except in a few isolated mines, it has not been the practice to divide the workings into districts by leaving barrier pillars of coal. Under such conditions, the only places available for stoppings are in the galleries, which are perhaps 20 ft. high and 15 ft. wide. A dam of such an area, unless of enormous thickness, will burst under the sudden pressure of an air-blast. In any case it would be impracticable to make gas-tight dams in such large galleries in a short space of time.

Therefore, the only alternative in case of fire in many Indian collieries is to cover over the shafts or to fill them up. The conditions at the mouths of many shafts make the covering of them difficult, and filling them with earth is an extremely slow process where the approaching galleries are about 20 feet high. Shafts are numerous and interconnected over large areas and in many cases there are no boundary pillars between mines even when these are worked by different owners.

Importance of Creating Separate Districts

Thus, a fire may involve the closing of a group of collieries; and this closing may be permanent if falls extend to the surface. Fire will spread with marvelous rapidity in the coal mines of India because the local falls of roof, which do much to check the spread of fires in other countries, are absent. When falls occur in a fire area they produce air-blasts which drive burning gases in all directions, and extend the fire to distant workings. Fortunately provisions against these dangers can easily be made by dividing the working areas into districts and panels with barrier pillars between them. All the galleries cut through these large pillars should be small, not more than 8 ft. wide and 8 ft. high, and dams should be put in them as soon as coal working is finished in the district which they serve.

Gas Engines for Collieries

By E. L. Chorlton

In continuation of his discussion on the advantages of the use of gas engines in connection with by-product ovens and producers, Mr. Chorlton shows that fans, pumps and mining machines may be driven directly by gas engines, and that with air compression to aid in starting, hoists and haulage drums can be similarly actuated.

In the pneumatic system the power is converted into air-compression, and although the efficiency of this method may be less than either of those previously mentioned, it is more flexible than the hydraulic system, and as to safety is superior to a direct use of the generated power. Consequently it is still much used, and practically all collieries have such a compressed-air plant. Moreover, an increase in its use seems likely, if any further restriction is put upon the use of electricity underground. The efficiency seems to average only 30 per cent. This, however, is largely due to causes which might be obviated, as, for instance, by the use of more efficient air engines in the mines.

The direct driving of air compressors by gas engines with an automatic control, which varies the speed according to the demand, although an eminently practical proposition, has not, at any rate so far, been adopted to any extent at collieries.

This automatic control of gas engines is easily applied to the two-cycle type, and the following is a description of a plant which has been in use for two years. So successful is this type of plant that it is almost always more economical to install it than any other, even at existing collieries, where it may have to be worked from a separate producer. Figs. 1 and 2 show the general arrangement of the plant. A producer is used here because no coke-oven or other waste gas is available. It is in a separate room, and is walled off so as to keep the main engine room clean. Important points in the general scheme are the accessibility and the ease with which the whole installation is manipulated. It has been so arranged that one man can easily attend to the entire plant, thus not only is the fuel cost low, but the labor charges are small.

A Two-cycle Gas Engine for Colliery Use

The engine is of the two-cycle double-acting type, and embodies the latest improvements. Its suitability for the actuation of air compressors is largely due to its being the only gas engine with a single cylinder in which an impulse is given at every stroke. The maximum speed of the engine is 120 r.p.m., and can be slowed down automatically to as low a speed as 30 r.p.m., its action being similar to that of a steam-driven compressor. The piston rod is carried through a stuffing box fitted with metallic packing, and is connected to an external crosshead, as in ordinary steam-engine practice.

There are two inlet valves, one at either end of the cylinder, and the exhaust gas is blown through ports set midway between them. This exhaust is followed by an incoming charge of scavenging air, entering through one of the inlet valves. These valves are operated by an eccentric rod from the main shaft through a pair of rolling levers, from

which a simple motion also operates the trip gear to the magnetos. The flywheel is 14 ft. in diameter, and weighs 13 tons. It is cast in two halves, with a barring rack round the periphery.

Control by Speed and Air Pressure

There are two methods devised for governing the engine; one of them consists of a governor mounted directly over the crankshaft, and driven by spiral gearing. The governing is effected by a small butterfly valve, connected with the governing rod, which permits just enough gas to enter the power cylinder to meet the requirements of the load. This governor is simple, and is fitted with an attachment by which the maximum speed can be adjusted within certain limits while the engine is running. It only comes into action as full speed is approached.

The other method provides a special dashpot governor, which controls the engine when the pressure of air in the receiver exceeds the required maximum pressure. It reduces the speed automatically in direct proportion to the amount of air desired, thus economizing fuel.

In my experience of compressed-air installations for mines, I have observed that the air was nearly always economically compressed, the design of the plant being evidently the result of considerable thought. On going below ground, however, efficiency seemed to have been entirely overlooked, as engines and pumps of the most uneconomical description were employed. So common does this appear to be, that I am inclined to ask: Who, and where, are the makers of efficient air motors in this country? In America, and in some other countries, much better plants seem to be used, and many schemes are in vogue for increasing their efficiency, such as the closed-circuit system. As the air pressure required for coal cutting and similar work is so low, the air might first pass through other plants for pumping, etc., before going to the cutters.

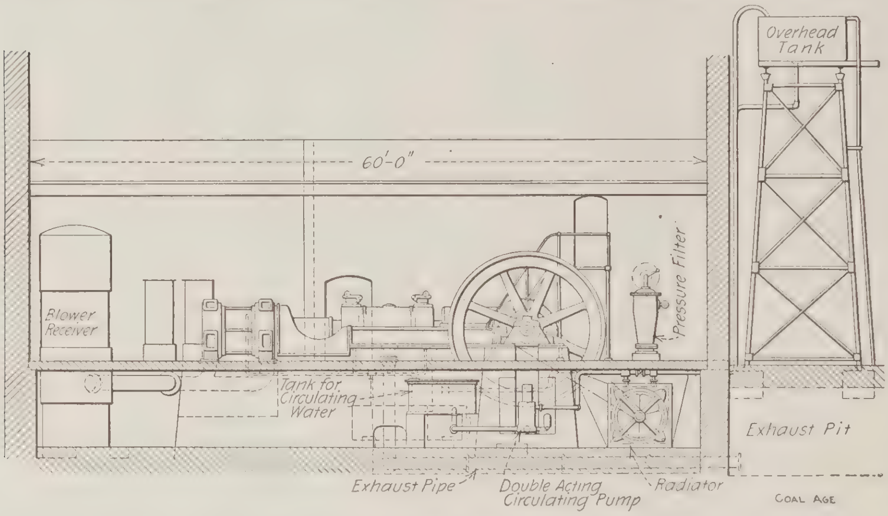

Fig. 1. Elevation of Gas-driven Air Compressor

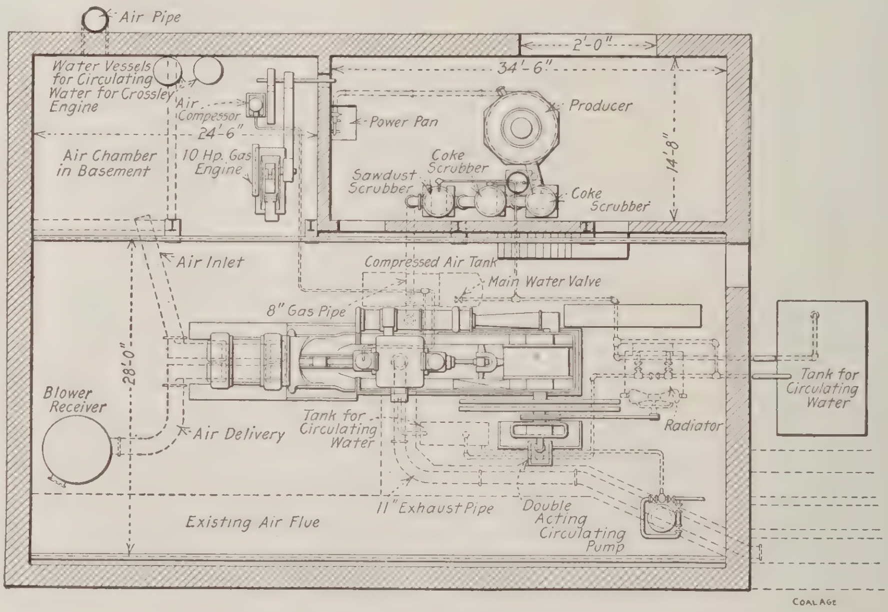

Fig. 2. Plan of the Above, Showing Gas Producer

The Mechanical or Direct Scheme

Hoisting with a direct gas-engine drive presents several difficult problems, and up to the present, I am unaware of the use of this method at any colliery. It seems hardly possible to operate the main hoisting drum of a shaft by the use of gas engines unaided by any other device. There are usually so many stops and starts for decking, so much reversal of the direction of hoisting, that we must look further, therefore, for some additions to the gas engine if it is to be made to meet the various requirements.

One method of circumventing these difficulties effectively would be to install a gas-driven hoisting engine, conforming in general layout to a standard twin-cylinder steam engine, the gas engine being of the two-cycle type, with its great advantage of quick starting. Behind each cylinder would be situated air cylinders, with the pistons coupled to and acting on tailrods from the gas cylinders in front. It will be seen, therefore, that with compressed-air auxiliaries the hoist can be run with an air engine being operated like a steam hoist when starting and decking, and making an inspection of the shaft, etc. To accomplish in an economical manner the general duties of hoisting by the addition of such air cylinders, I propose to connect them with a reservoir of relatively small dimensions, the capacity of which can be easily regulated by the addition or subtraction of water.

How Air Reservoirs Could Store Energy of Cage

Supposing now that the gas hoisting set is running at full speed in the middle of the hoist; the air cylinders, being put out of service, are ineffective; when the period of deceleration commences to bring the hoist to an end, they are thrown into circuit with the air receiver through the operation of a valve gear, and then, acting as compressors, they rapidly raise the pressure in the receiver on a curve corresponding to the deceleration curve of the moving cages. Thus the kinetic energy of hoisting is stored in the air receiver, and the cages are gradually slowed up, until finally they are brought to rest by a brake. The pressure thus stored is then available for restarting the engine on the next hoist, the gas-engine cylinders coming into play as soon as movement takes place. Thus these cylinders would act alternately as compressors and motors. It is obvious that by this means a considerable economy could be secured, positive starting and control effected through the air cylinders, and all this with a considerably smaller gas engine than would otherwise be required. Of course, there is some loss in the compression and re-use of the air, but this is largely corrected by reheating it before

it is used by means of the exhaust from the gas engine, and, when necessary, by storing the power given out by the engine when running at high speed. Thus, the period of starting up when the stored air acts as a motor will be shorter than that during which power is being accumulated at the end of the hoist. The figures regarding this scheme are unfortunately not yet worked out in such a way as to enable me to present them in satisfactory form.

As Efficient as Electric Hoisting

With reheating, the overall efficiency may be as high as or higher than that of the electric hoist. More important at the moment, however, is the fact that it seems to make gas hoisting a distinct possibility. It is well worthy, therefore, of consideration, with the hope that ultimately further practical demonstration and improvement will result.

There are other ways of regenerative working which secure the object desired, and of these, one is by a hydraulic engine to replace the air cylinders, water being substituted for air and used afterward as motive power.

A further variation, which, however, the writer has not yet developed, seems to suggest possibilities of increased simplicity. In this case a balance rope is employed, such as was used in certain shafts many years ago, and an example of which I have seen working at the Wharncliffe Silkstone Colliery before mentioned. In this system I propose to use a similar rope or chain to lap onto a conical drum for the slowing part of the hoist and to unlap for the accelerating part, and, instead of attaching to the end a balance weight, to employ a connection to the piston of a small capacity air-storage cylinder, such as is used in the previous plants.

Fans and Pumps

The direct driving of a ventilating fan by means of a gas engine is not a difficult problem. The method is already in use, and therefore it does not need further discussion.

Pumping presents a much easier problem than hoisting. Because, in mining work, the pumps will be necessarily below the surface while the engine is above, a design with pump-rods would have to be adopted. In the usual type of pumping reciprocators, flywheels are not used to regulate their action. This absence of a flywheel renders it much more difficult to apply gas as a driving agent. In this non-rotative type, steam cylinders would be replaced by gas cylinders, with the addition of suitable hydraulic compensating cylinders, such as have been employed on Worthington pumps to even out the irregular driving force exhibited so plainly in gas-engine indicator cards. The ignition is controlled from the differential gear in a suitable manner. It is essential that such gas cylinders should be of the two-cycle type, for by this means only can the excessively slow speed of this type of pump be obtained. The provision for a continuous and even absorption of power from a source which creates it, discontinuously and unequally, is so difficult that a rotational pump driven by gas must be considered a much cheaper and more satisfactory proposition in every respect. Fig. 3 shows a general layout with pump-rods actuated through bell cranks and passing down the shaft. Pumping can otherwise be performed by wire-rope driving in the dips and in the more remote parts of the mine.

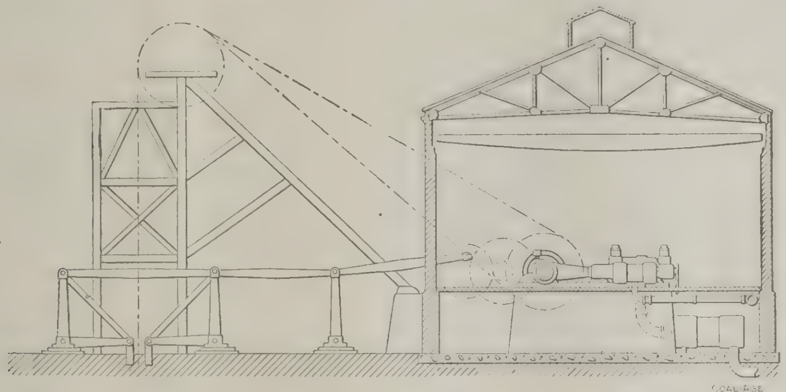

Fig. 3. Diagrammatic End Elevation of Colliery Plant Actuated by a Gas Engine and Mechanically Driven

Haulage and Coal Cutting

Many of the older collieries were equipped with direct mechanical drives, actuated by steam engines on the surface, and it does not seem that any insuperable difficulty should be found to result from the substitution of gas engines in place of the original prime movers.

Haulage is nearly always effected by wire ropes from haulage engines situated at the shaft top or bottom. In the direct mechanical system this drive is operated by means of a band rope actuated by a gas engine; and it is this rope, with its proneness to failure and its interference with hoisting, which is the undesirable feature of the mechanism. This objection, however, should not be insuperable, when the care and supervision necessary for all modern machinery are exercised. Such drives, worked by steam engines, are in common use, and seem to be both satisfactory and efficient. The writer has had the pleasure of seeing one or two modern installations of rope transmission, and he was impressed by the general simplicity and completeness with which these various requirements were fulfilled. The steam engine operating on the surface could easily have been replaced by a gas engine fitted, as an additional means of flexibility, with a reversing mechanism and the usual connections for starting by compressed air.

Coal-cutting machines, although often driven electrically, are more generally operated at the present time by compressed air. They can be operated effectively by wire ropes, as was done in the first mechanically operated machines. Efficiency could undoubtedly be increased if the various rope wheels were mounted on ball- or roller-bearings, the success of which for duties more onerous even than those in connection with mining has of late years been most marked.

The Chilean Coal Market

The demand for foreign coal continues good, notwithstanding the increased output of the Chilean mines, which amounted to more than 1,000,000 tons for 1911. The imports of coal for 1911 amounted to 1,274,118 tons, against 1,293,140 tons for 1910. Of this England furnished 705,762 tons, and Australia 526,643 tons, against 861,887 and 426,867, respectively, for 1910. No American coal was imported during 1911 and only 7260 tons during 1910. Only 51,861 tons of American coal have been sold in Chile during the past six years.

Briceville Explosion

E. N. Zern, assistant professor of mining, University of Pittsburgh, in an address to the Monongahela Y. M. C. A. Mining Institute, made the following reference to the Briceville explosion.

"Not long ago we read of a terrible mine disaster. These are the facts: The state mine inspector permitted a mine to be operated, the ventilation of which was provided by a fan installed within the mine. This mine was gaseous and dusty, and was neighbor to a mine where 10 years before 184 men lost their lives in an explosion. Open lights and electricity were permitted and their use can be classed in no wise as a precautionary measure wherever gas is generated, but the crowning fault lay in the use of that agency which, in the past ten years, has sent an army of men to the great beyond—black powder. In view of the dangers which were known to exist at this mine, I say that the loss of these 84 lives due to a blown-out shot is absolutely indefensible."

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

The fuel wealth of West Virginia has not been won by weaklings. In this little mountain state, Nature was lavish in storing her gifts, but all the good things were locked up in the fastnesses of her hills, and located far from the highways traveled by lovers of comfort and ease.

One of the pioneers in the development of West Virginia was Alexander Laing, father of John Laing, the present head of the State Department of Mines. The elder Laing emigrated from Falkirk, near Glasgow, Scotland, to America, in June, 1867. The family located at Hermitage, a small mining town, near Sharon, Mercer County, Penn.

John having been born in Falkirk, in August, 1865, was less than two years old when his father and grandfather came to this country. As soon as the family had located in Pennsylvania, the older men secured employment in the mines of Mercer County, continuing there for some years, but later changing their residence and devoting their time to mining in Mahoning County, Ohio.

John Laing entered the mines in what was known as the Spearman Shaft, Mercer County, Penn., at nine years of age, and his attention has been directed solely to the production of coal ever since. Mr. Laing accompanied his family to Ohio, and worked in the mines of that state until 1884, when they all moved to Fayette County, West Virginia.

John worked in the mines of the New River and Kanawha districts until 1891, when he gave up underground work and accepted a position as clerk in the store of the Rush Run Coal Co., in Fayette County. He was later advanced to bookkeeper, and as an additional duty, had charge of the company's payrolls. In January, 1892, when 26 years old, Mr. Laing gave up office work and took charge of the mine of the Red Ash Coal Co., as mine foreman. Five years later he was promoted to the position of mine superintendent of the Red Ash, Brooklyn and Cunard properties, three of the earlier operations located on New River.

In 1898, John was made superintendent of the mines of the Rush Run Coal Co., and in 1901, when a consolidation was effected, bringing together the Rush Run Coal Co., the Red Ash Coal Co., the Brooklyn Coal Co., the Cunard Coal Co., the Sun Coal Co., the Lanark Coal Co. and the Royal Coal & Coke Co., all located in the New River district, he was appointed superintendent of the combination. After this consolidation, the company was known as the New River Smokeless Coal Co., and was under the active management of Ferdinand Howald, one of the early settlers, who retired from mining in 1905, after having accumulated a considerable fortune. On the retirement of Mr. Howald, John Laing was appointed to succeed him as general manager of the consolidation.

John Laing

During the latter part of 1905, the New River Smokeless Coal Co. sold its entire holdings to the Guggenheim interests, of New York City. When this deal was put through, Mr. Laing resigned from the new organization, and with a part of the proceeds received from the sale of his interest in the original company, he organized the Wyatt Coal Co., in Kanawha County. He also purchased four mines on Cabin Creek from the Cardiff Coal Co., and these properties, known as Horton Nos. 1 and 2, Oakley and Berlin, are still being operated under his personal management.

In 1908, John Laing organized the MacAlpin Coal Co., which concern is operating on the Virginian and the Chesapeake & Ohio railways, in Raleigh County, West Virginia. He is president and general manager of this company. In 1911, John organized the McGregor Coal Co., which corporation has a lease of 3600 acres, located in Logan County, West Virginia. In 1912, he organized the McCaa Coal Co., which concern is working a lease of 1000 acres in Gilmer County, West Virginia, on the Coal & Coke Ry. John is likewise president and general manager of this latter corporation.

On December 22, 1908, Mr. Laing took oath of office as chief of the Department of Mines of West Virginia, which position he has filled creditably, and to the satisfaction of both operator and miner. His term of office expires July 1, 1913, and although he expects to serve until the end of his appointment, he will not accept the office for another four-year term.

In his own words, Mr. Laing says: "My work as chief mine inspector has been both congenial and pleasant. I have at all times had the coöperation and assistance of the Governor and administration of the state, and my relations with the operators and miners have been unusually harmonious. While at times we have had a slight diversity of opinion, and although a few accidents have occurred, we feel that our efforts have been successful."

Having been raised in the mines from early childhood, and having filled every position from trapper boy to president and owner, John Laing knows the practical side of his business from A to Z. He is a plain man and a strong one. Having mined coal himself, he knows his men, and it is not difficult for him to grasp their point of view. A natural story-teller, John would rather spend an idle moment telling a "new one" than to attend a reception at the Court of St. James.

His education was secured in the college of "hard knocks," but the schooling he received is the kind you can't forget, and the man who can start as a trapper at nine and swim to shore early in life, with several hundred thousand gold shekels on his back, has something thicker than water in his veins and stiffer than cord in his spine. Best of all, in his climbing, John hasn't walked on the hearts of his friends, and used the hopes of associates and acquaintances as stepping-stones to success.

Loyalty to friend and clan is not the least of his virtues, for what he hasn't done for "kith and kin" wouldn't fill a paragraph. Perhaps it's the Scotch in him, but I am inclined to believe its the size of his heart and not inherited instincts that is responsible for his desire to advance the "House of Laing" rather than the personal fortunes of John.

Correspondence suitable for the columns of COAL AGE solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Entered as second-class matter, October 14, 1911, at the post office at New York, New York, under the act of March 3, 1879.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of Coal Age, we will print 7500 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.

This journal has a direct aim—a single purpose—which is to help advance the coal-mining industry. Its creed embodies the dissemination of knowledge and the free interchange of ideas among its readers, all of whom are invited to become regular contributors.

COAL AGE

The Recompense of Labor

Were there but one individual in the world, it would be easy to determine the meet recompense of his labor. We could be assured that this solitary wight would receive, and could only receive, for his happiness and his sustenance what he gained by delving and spinning, less what was taken away from him by the rough hand of nature.

But, in the present, with a complex system of society, when some individuals take specialized parts of the corporate burden and others lightly shirk their responsibilities, we sometimes permit ourselves to believe that what is true of the unit man is untrue of the agglomerate unit, society. But it is certain, no matter how often we may overlook the fact, that society as a whole, cannot earn unless it works, and works efficiently, thereby creating wealth.

Wages are but tokens of the share awarded to the individual, representing his claim to a part of the universal wealth, and the attempt to issue these tokens without restriction will but cheapen them, because they do not call for segregated portions of the common store, but for such a part of the whole as the individual token bears to all tokens issued. Let us not fear, the wages of the world will buy the product of the world. No matter how liberally we recompense labor, the pay of the workmen cannot purchase more than what is for sale; nor can wages be so low that they can only purchase a part of all things salable. And this adjustment whereby the public's money and the public's property become equal automatically is provided in two ways—by changing the price or by controlling the product. The adjustment is foreordained, and for the sake of human betterment should be reached in times of depression by price reduction, and not by the idleness of the producer.

These are sayings so trite that we hesitate to make them. Unfortunately they are too often forgotten, and we hear it declared that class consciousness, liberal laws and the coming of labor into its own, express a sufficient reason why the workman is prosperous. But after all there can be no sufficing prosperity, unless the ground will produce and man will work intelligently at production.

The political intelligence of the American workman has not, in any way, been the cause of his personal well-being, and we fear his socio-political agitation will land him and the whole country further from his social ideals.

But it is with no feeling of satisfaction that we now proceed to condemn extensive rises in wages. It seems natural for every man to look forward to a time when his statement will run into three figures. When he has reached the highest point open to his intelligence, he naturally seeks to raise his class of fellow workers to higher levels of remuneration, in the expectation of personal advancement. He sometimes believes that this increase in wages will be taken from the profits of capital. But if he reflects, he must know it comes from his fellow workman, who must pay a larger price for the article he produces.

We cannot condemn him for shallowness of vision or for callousness toward his brother worker. The average capitalist sees no further than do his wage-earners and raises his prices regardless of the public weal or woe. So in this seeking of a larger wage, the worker commands everyone's sympathy. It is realized that no matter how inept, degenerate and feeble he may be, and few there are who can be thus described, his needs and those of his family are none the less urgent. He and they, as much as the intelligent, brilliant and strong, need sustenance and the luxuries of life.

But these can only come if there is a product of toil sufficient when divided to give an adequate share to each man. If the product sinks so low that there is not enough for all on the old standard of living, then "real wages" must fall, even if the "nominal wages" soar to suit the demands of agitators. The real wages, as Adam Smith has said, are the

materials desired by the workman, and exchangeable by him from the nominal wages given him by his employer.

The real wages of America have been high despite, and not because of, the deplorably high nominal wages. With virgin forests of excellent timber, with coal outcropping to the surface, with land unspoiled by endless tilling, with iron which can be mined by a steam shovel, with magnificent waterways, and above all with laboring men of a high degree of intelligence directed by enterprising industrial leaders and animated by the hopes which a large real wage inspires, there could not fail to accrue to workingmen an enviable opportunity. That this well-being was due to the men and to the land in which they lived, and not to any altered relation in the distribution of profits between capital and labor, is shown by the fact that both capitalist and artisan profited at least as largely as in any other country.

The only drawback to national supremacy has been and is now to be found in large nominal wages, and the accompanying high prices. But we are not the only people held back by such an encumbrance. New Zealand, Australia, and in a lower degree Canada are similarly hampered. All new communities, knowing how a large wage appeals to outsiders, offer it freely to encourage immigration of specially fitted foreign workmen. Able to pay such wages, even when elbowing their way into foreign markets by virtue of cheap raw materials and boundless vacant lands, capitalists do not hesitate to increase the rates of pay unduly.

Moreover, these larger wages have been paid usually to the invited guests of the nation; in early days, for example, the miner received more per ton of coal mined and loaded than the average day laborer got for a day's work. Today the glass workers, the tin-plate workers and the iron rollers, through their unions, have maintained, not the American wage, but the artificial wages offered to them before their entry on American soil, having held up the standard by selfish interferences with the laws of supply and demand.

High nominal wages shut or tend to shut the products of industry out of foreign markets. When nominal wages are equally raised in our country and in those competing, then there is no disturbance in business from such a rise, but when larger increases in wages are made here than abroad, the American product must find all its trade in the home market. Thus the work of consuls in building up a foreign trade is continually nullified by home conditions which are purely artificial and which aid no one.

The Bureau of Mines

Not a few organizations have been destroyed by the excess zeal of their friends, and such a result, the Federal Bureau of Mines has much reason to fear. The mining public is too well instructed to accept as official and authoritative all the statements that seem to emanate from Pittsburg and Washington. However, the average layman, unacquainted with the facts, is likely to be misled, and shaken confidence is sure to result when the public is at last correctly informed.

J. W. Paul has been credited with the statement that "at the explosion at McCurtain, Okla., 25 men were saved out of 100 in the mine." The alleged quotation does not declare that the men owed their lives to the Bureau, though the whole statement labors hard to create the impression that the Bureau is to be credited with the rescue of all the 25 men. Our readers will recall that eleven of the men escaped long before any member of the Bureau heard of the disaster. The others, possibly, may have been aided in their escape by the fact that the Bureau directed the recovery work and helped to reëstablish the air current in the mine.

Let the Bureau deny all attributions of bravery and judgment, which do not rightly belong to its rescue corps. Let it give due credit to the inspectors and the local rescuers who work so bravely to save their fellowmen. There is surely glory enough for all. The bravest are usually the most modest and the first to deny stories which overstate their achievements.

But there are other journalistic deliquencies besides those relating to mine-rescue work. A tendency of the advocates of the Bureau has been to lay claim to the origination of every mining improvement, forgetting that many of the developments have come from over sea. This does not show in the bulletins issued at public expense, but it does appear in reading notices scattered far and wide all over the country. These notices are the well springs of no little justifiable criticism and the Bureau must curb its friends or it will itself be curbed. From all sources comes the assertion that the nerve centers of the mining industry do not center in a common ganglion situate in the group of buildings at 40th St. and Butler, Pittsburg, Penn.

It should never be forgotten that the best friends of this organization are not the noisy press writers who know nothing of mining. Those who are working along the same lines as that body will recognize freely all its steady, honest and painstaking investigation. But gasconades and overstatements, whether made by the Bureau or by perfervid press journalists can only do harm. We would ourselves be the first to deplore the Bureau's besmirching and destruction, but these evils are likely to result if the present lack of conservatism continues to be evinced by those whose writings proclaim them accredited press agents.

Let it never be forgotten that we may wipe entirely off the slate all those foolish commendations to which the Bureau is not and never will be entitled, we can whittle away all the dross ornaments of editorial pens and there will nevertheless be much of which this governmental body and the people of these states may be justly proud, and we and they, are but at the threshold of their worthy attainments. Where so much is good, when false claims are unnecessary, there is no need to fear that the lopping of fallacious honors will leave Joseph A. Holmes and his associates despoiled of all honor. Let us hope that hereafter the Bureau will urge the press to regard and acclaim it with that measure of dignifying and honorable approval accorded the Bureaus of Standards and of Roads. Let it pride itself on the following aristocratic medieval motto, "Moveo et taceo,"—I move ever forward but I hold my peace.

Many annoying mine delays, caused by waiting for parts to be sent from the factory, can be avoided if only standardized, interchangeable equipment is used. The importance of this item in time saving cannot be overestimated.

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Timbering a Mine Parting

Answering Noah Burton, Anglin, Ky., Coal Age, March 23, p. 786, who asks for the best method of timbering a mine parting under a tender roof, I submit a few sketches showing some of the methods I have adopted, in different mines. Each of these methods gave good satisfaction in the place where it was adopted. In timbering a mine parting, several conditions should be considered before adopting a method; as for example, length of service required of the timber; approximate weight it is expected to sustain; whether the siding will be temporary or permanent; whether the timbering will take up too much room and reduce the sectional area of the airway required for ventilation; whether or not the mine is in a good timber territory, or whether the timber will have to be bought and shipped in, and finally its cost as compared with steel I-beams, or T-rails.

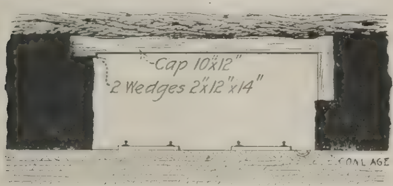

Fig. 1. Crossbar and Short Leg

Fig. 1 shows a method of timbering where the coal is reasonably hard and will sustain a good pressure. One end of the crossbar is notched into the coal, and rested on a plank to give it a better bearing surface. A wedge is then driven between this plank and the timber; or a pair of wedges can be used instead of a plank and wedge. This will reduce the liability of splitting off the edge of the coal supporting the timber. On the other side a short timber or leg is stood on the coal.

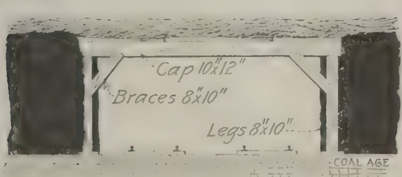

Fig. 2. Braced Timber Frame, Legs Set in Coal

Fig. 2 shows a method of using two legs and a cap or collar, and two braces of the same sized timber notched into the cap and legs as shown. This arrangement lessens the span and strengthens the collar. In both of these sketches the posts are cut into the coal on each side, and set back far enough so that a runaway car, or cars that become derailed will not knock the timbers out. The coal is cut just wide enough to admit the timber legs.

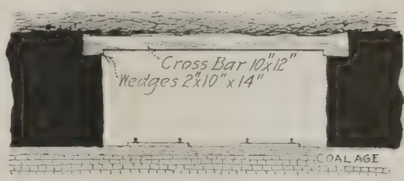

Fig. 3. Crossbar Supported by Hitches in Coal

Fig. 3 shows a method where the crossbar only is used. One end is slipped into a slot cut in the coal, the other end being swung in sideways, and the bar tightly wedged against the roof and the sides. Both ends of the bar rest on a short plank and wedges to give a good bearing on the coal. This is an economical and effective method where the coal is hard and will not split or crack off.

The timber frames can be set about 3 ft. apart, and lagged on top with 2-in. plank.

Fig. 4 shows a method of making a crossbar out of two steel rails, bolted together, with a wooden chock or filler between them. The ends of this bar are supported by two wooden legs. The sketch shows the general arrangement at one end. This bar is simple, easily constructed and will sustain an enormous weight and

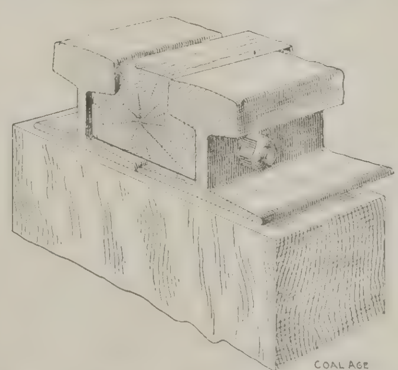

Fig. 4. Crossbar of Two Steel Rails

last a long time. The chocks do not reach the entire length of the rails; they are only about a foot long and placed where the bolts go through. Plank lagging can be used above the bars as with the other timber sets; or small iron rails, 16 lb. per yd., could be used, providing the roof was not too frail, requiring the lagging to be set skin to skin. This method is probably cheaper than the regular steel I-beams often used for mine timbering.

Fig. 5 shows a concrete arch with more than one radius. This is probably the most expensive first-cost method of supporting the roof over a sidetrack; but where the mine atmosphere has a corrosive effect on steel and rots wood, and where permanency and security are the chief factors to be considered, it is the best way to secure the siding or parting. This is especially true in shaft bottoms and landings. Where the weight to be sustained is great, and the excavation limited, the concrete can be reinforced with iron or steel to strengthen it.

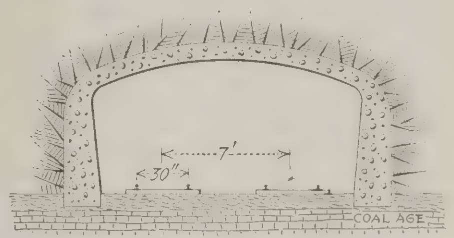

Fig. 5. Concrete Arch over Roadway

Not knowing the track gage, or the height of the seam, I have given no figures beyond stating the usual sizes of timbers used for mine partings in the bituminous regions of Pennsylvania. In estimating the cost of the job, it is necessary to consider the available supply of steel timbers, and of wooden timbers. The costs will probably be equal, in a territory where timber is scarce.

Johnstown, Penn. R. Z. Virgin.

The Utilization of Low-Grade Fuels

I was much interested in the Foreword, in Coal Age, April 6, which referred to the possibilities of the gas producer as an economizer of fuel for power purposes. The article draws attention, in a brief manner, to the fact that the gas producer has made it possible to use fuel that cannot be employed under a boiler because of its low calorific power, large ash content, or other cause that would make it an expensive fuel for this purpose. The statement is made that one ton of coal will turn more wheels operating through a producer and gas engine than two and one-half tons of the same coal burned under a boiler in the usual manner. This is an encouraging statement.

As master mechanic for the Cannel Coal Company of this city I have been studying the development of the gas producer, for some time. In preparing our

product for market we make one grade of coal (crushed-bone coal) for which there is little demand at the present time. There is a chance to sell electricity near here, for irrigation purposes; and we have thought, for some time, that this low-grade fuel, for which there is a limited market for power purposes, could be utilized through a gas producer and gas engine to furnish the power for an electric plant. I think such a gas producer and gas-engine-power station would be much better than a steam-power plant, in the economy of its operation. The article to which I have referred states that no coal is too poor for producer-gas purposes, and that coal containing even as high as 70 per cent. of ash has been used in this manner.

We have corresponded with a number of gas-producer manufacturers, but have found none who are willing to make any guarantee that this fuel could be used. If the statements to which we have referred are true, and we believe they are, we cannot understand why gas-producer companies should hesitate to assure us that their producer will work with this grade of coal.

The coal we mine is a semi-bituminous coal, called here "cannel coal." It gives on test about 15,000 B.T.U. The coal is very high in volatile matter, but has a large ash content. It is a long-flaming coal. The crushed-bone coal to which I have referred is what might be called a byproduct, in the preparation of our coal for market. I believe tests of this crushed-bone coal have shown about 8,000 B.T.U., with, of course, a somewhat larger percentage of ash than the regular coal.

I have suggested that our company should ship a car load of this crushed coal to some manufacturer of a good type of gas producer and have them try the same to ascertain the result. I would be glad to learn the name and address of such a manufacturer of gas producers, who would be willing to make such a test. I believe there is no fear but that the test would be successful.

W. F. Shutt,
Master Mechanic,
Cannel Coal Company.

Darwin, Webb County, Tex.

[It is possible there is a large amount of impurity in the crushed-bone coal to which our correspondent has referred. If this impurity is of a nature or in such quantity as to obstruct the grate and reduce to a large extent the temperature of the combustion in the gas producer it might be impossible to use this coal for the purpose mentioned. As cannel coal is one of the best gas producing coals, it is very possible that even this low-grade byproduct could be used in a gas producer; but it might require some previous treatment in order to separate a portion of the impurities. It might be necessary to wash the product before using the same in a gas producer. We would suggest that an analysis of the crushed-bone-coal product should be made, as this would greatly assist in solving the problem. It is a good proposition and should develop some valuable ideas in regard to the utilizing of low-grade fuels.

Coal Age will be glad to hear further from those who have had experience in this direction.—Editor.]

Treatment of Boiler Water

There is only one sure way of determining the proper treatment for boiler water, and that is to have it thoroughly and carefully analyzed. Then if there are properties in it which will cause either pitting, scales, or other boiler troubles, have chemists who make a study of this business prepare a compound or treatment specifically for this kind of water.

There are a great number of methods for treating boiler water, some of which are highly advertised. Many claims and counter claims are made, and experimenting indiscriminately with different methods is apt to discourage one from using any.

In time we will probably reach a stage of industrial development where practically all of the water used for steam will be analyzed and treated, if necessary, before it is used. Even the surface waters carry impurities that may produce scale or pitting, and it is so common among the miners to get water that is injurious that it is not safe to run a boiler any great length of time without carefully examining it. The better plan is to analyze the water and know before you start.

Injurious Impurities

Sometimes water strong in sulphuric acid derived from iron pyrites, or arsenical iron pyrites, will cause dangerous pitting of boiler tubes in only a few moments. This is a difficult water to treat.

The most common trouble with water that is seemingly practically pure is its leaving behind a sediment of lime or silicate, or a mixture of lime and clay that has been held in solution. This is quite common even in apparently pure surface water and it is this that forms what is termed scale in the boiler. Scale is not as bad as acids that will eat the metal of the shells and tubes. If neglected, of course, even scale proves dangerous in the end, but it is comparatively easy to clean out and remove.

The safe and sure plan is to send samples of the boiler water to chemists who make a specialty of boiler compounds; have it analyzed, and treatment prescribed according to its needs.

The Fireboss Question

I have been much interested in the discussion that has been going on for some time, in Coal Age, regarding the fireboss question. I am, at the present time, employed as a fireboss in western Pennsylvania. From my own experience I can indorse much of what has been said in regard to the general treatment of the fireboss. Whenever there comes an idle day and the mine foreman is aware of it in time to stop the fireboss from making his rounds or morning inspection, he is there at the mine entrance to stop them from going in or sends word and they are sent home after having risen at 2 o'clock in the morning and prepared themselves for the work and traveled sometimes a long distance to reach the mine in time.

The mines here mostly ship by river. When the river was frozen over last winter and the mine was idle, the firebosses were laid off or allowed the choice of working every other day, at a wage of $2.75 per day, which was 52c. less than their regular wage.

To show the difference between the treatment received by the firebosses and that received by other men in the mine, I would say it was a usual thing for the mine foreman to allow all the roadmen and their helpers and the day laborers to work every idle day. During last winter, when the firebosses worked every other day, these men worked every day.

It has been truly stated that during a period of idleness the fireboss should be the last man laid off, but during the idle period last winter, in our mines, the boss-driver and motormen got steady work; and one of these motormen was a new man, only recently hired since the mine had closed down on account of the freezing over of the river. All of the firebosses had been in the employ of the company a longer time than this man.

A Flushing Problem in the West

When constructing the new Federal Building at Rock Springs, Wyo., the engineers were confronted with the problem of filling in the old workings of the Union Pacific No. 1 Mine which were directly below the site of the building.

To attempt to haul material for filling the workings through the old openings would have been a laborious and expensive proposition. In order to save time, the government engineers are drilling a series of churn-drill holes from the surface and the material for filling the old workings will be spouted down these drill holes, making a perfectly solid foundation for the building.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Bituminous Mine Foremen's Examinations in Pennsylvania, April 9-11, 1912

Selected, Second-Grade Questions

Duties of Mine Foreman

Ques.—What are the duties of a mine foreman relative to his daily visit to each working place; what should he observe and what instructions give to the workmen?

Ans.—The mine foreman or one of his assistants must visit every working at least once each day while the men are at work. He must observe closely the condition of each place with respect to the health and safety of the men employed therein. He must see that the place is properly ventilated, drained and timbered; the coal properly mined and loaded, and proper breakthroughs made in the pillars. He must instruct each miner how to timber his place, mine his coal setting sprags not more than 7 ft. apart, and direct at what time blasting may be done. He must observe that sufficient timber and cap pieces are on hand, and that the fireboss has left his mark in the place, indicating that he has made his examination as required by law.

Ventilation, Water Gage in Two Airways

Ques.—If a water gage of 2 in. produces a velocity of 500 ft. per min. in an air course 4000 ft. long, what water gage will be required to produce a velocity of 800 ft. per min. in this air course, when its length has been extended to 8000 ft.?

Ans. — For the same cross-section (area and perimeter) of airway, the water gage varies as the length of the airway and the square of the velocity of the current. In other words, the water-gage ratio is then equal to the length ratio times the square of the velocity ratio. In this case, calling the required water gage x,

$$\frac{x}{2} = \frac{8000}{4000}\left(\frac{800}{500}\right)^2 = 2\left(\frac{8}{5}\right)^2$$

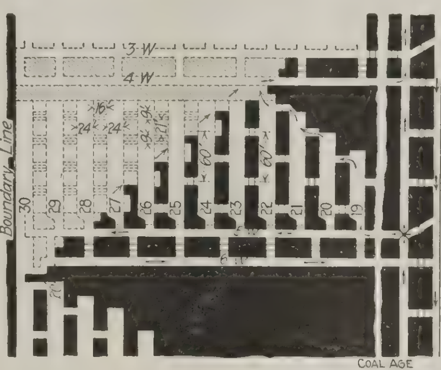
$$x = \frac{2 \times 2 \times 64}{25} = 10.24 \textit{ in.}$$

Drawing Pillars by Machines

Ques.—What method is best adapted to extracting pillars, in the mine, by mining machines, under ordinary conditions of roof and floor?

Ans.—The use of mining machines in drawing pillars requires experience and care. Few systems of mining will present conditions that will allow the machine to work with safety on the end of the pillar. With proper care, however, in the laying out and the prosecution of the work, the pillar coal will be sufficiently strong, under ordinary conditions of roof and floor, to enable the machine to undercut the rib of the pillar, back, say 3 yd. from the loose end.

A cut 7 yd. wide can generally be put in on the rib and the pillar cut through in this manner. The stub pillar 3 yd. thick is then mined out with the pick after setting the necessary timbers to protect the opening while the work is being done. The manner of crosscutting the pillars is shown in the accompanying figure, rib cuts being started in rooms



Showing Method of Drawing Pillars by Machines

24-27. Each 7-yd. rib cut is thus made with the machine, starting 3 yd. back from the loose end, and the pillar again cut through as before. Timbers are stood in this cut and the 3-yd. stub mined out by pick. This operation is continued till the entire pillar is taken out back to the entry stump

It is important, for success in drawing back pillars, especially when machines are to be used for that purpose, to lay out the work systematically and advance the rooms regularly with breakthroughs at a fixed distance apart. These breakthroughs should not be opposite to each other, but staggered, as shown in the figure. The line of pillar work must be kept, as nearly as possible, a uniformly straight line so that there will be a corresponding uniform line of fracture in the roof and none of the pillars will be unduly weighted, which would crush the coal.

In the accompanying figure the butt entries are driven to the boundary and the inside rooms turned first. The entire work is regulated so that the line of pillar work is continuous across the head of the butt entries. In the present case, the main-entry pillars are 10 yd. wide, the butt-entry pillars 8 yd. and room pillars 16 ft. All entries are driven 10 ft. wide; rooms are turned 8 ft. wide for 4 yd. and then widened out, on the inby side, at an angle of 45°, to a width of 8 yd. This makes the rooms 40-ft. centers; they are driven up 60 yd., leaving a chain pillar 20 ft. wide to protect the upper air course. The butt-entry pillars, in each case, are drawn with the chain pillar below them at the time of drawing the room pillars on the next lower butts.

Pressure on Mine Dam

Ques.—A dam in an entry supports a vertical head of water of 80 ft. The wetted area of the dam is 70 sq. ft.; find the total pressure, in short tons, on the dam.

Ans.—Assuming the wetted area is a rectangle 10 ft. wide and 7 ft. high, the center of pressure is one-half the height or 3.5 ft. above the floor. Then, if the water level is 80 ft. above the floor the effective head against the dam is 80 − 3.5 = 76.5 ft. and the pressure due to this head is

$$62.5 \times 76.5 = 4781.25 \text{ lb. per sq.ft.}$$

The total pressure on the dam is then

$$\frac{70 \times 4781.25}{2000} = 167.34 + \textit{short tons}$$

Ventilation, Height of Motive Column

Ques.—What would be the height of motive column, for upcast and for downcast air, respectively, where the depth of each shaft is 300 ft., and the temperature of the downcast shaft 32° F. and that of the upcast 48° F.?

Ans.—The heights of motive column, in terms of downcast and upcast air, are, respectively,

Downcast air,

$$M = 300 \times \frac{48 - 32}{460 + 48} = \frac{300 \times 16}{508} = 9.44 + ft$$

Upcast air,

$$M = 300 \times \frac{48 - 32}{460 + 32} = \frac{300 \times 16}{492} = 9.75 + ft.$$

The upcast air being the lighter gives a longer motive column for the same pressure.

For the Betterment of Living Conditions in Mining Communities

Emergency Car of Colorado Fuel & Iron Co.

Special Correspondence

The emergency car of the Colorado Fuel & Iron Co. has equipment features of more than ordinary interest. It is intended to supplement the rescue car proper, which carries the regular rescue equipment.

It is a standard box car, fully equipped for train service. It carries a 5-ft. disk fan, manufactured by S. B. Stine, of Osceola Mills, Penn. This fan has a sectional base with two bearings bolted together, which support the fan independently. At one end of the fan is a flexible coupling for attachment to any one of three motors. A base is carried in the car to support any one of the motors when in use. It is designed and built of sufficient strength and size to accommodate the largest motor, and is provided with the necessary liners, which match the bolt holes in the bases and bring the motors up to the correct height for alignment with the fan. These two parts, the fan base and motor base, when bolted together, complete a direct-connected fan unit of substantial construction.

Motors for All Kinds of Current

The different mines use current of different voltages. Moreover, at some direct current is used, and at others, alter-

nating. To fit the different conditions, the Fuel Co. has installed three motors, suitable for every type of current supplied. The motors will operate the fan at any required speed, from 150 r.p.m. to 600 r.p.m. They are equipped with the necessary controlling apparatus to provide for the above range of speed. Each motor is fitted with its own corresponding half of flexible coupling, so that it is not necessary to change couplings when motors are changed.

The following is a description of the three motors:

One 20-hp. direct-current motor of the semi-inclosed interpole type, using from 250 to 500 volts, and running at 550 revolutions per minute.

One 20-hp., 25 cycle, 3-phase alternating-current motor of the semi-inclosed, wound-rotor induction type, using 440 volts and running at 480 revolutions per minute.

One 20-hp., 60-cycle, 3-phase, alternating-current motor of the semi-inclosed, wound-rotor induction type, using 440 volts and running at 575 revolutions per minute.

These motors were furnished by the Allis-Chalmers Co. To facilitate transportation of the fan, the three motors and the adjustable motor base, each piece is equipped with specially designed trucks, or dollies. These are constructed to fit mine tracks, gaging 36, 38 and 40 in. On the car are also carried 2000 ft. of No. 4 wire, inclosed in a duplex rubber-covered cable, wound on a reel; also two 4-ton jacks and ropes, blocks, chains, and gangplanks. A supply of fireproof brattice cloth is set in racks on the sides of the car.

The Helmet Car

These supplies are supplemented by those carried on the helmet car, and it is the intention to move the cars together to the seat of any disaster. On the helmet or rescue car is carried a full supply of shovels, picks, axes, saws, hammers, bars, sledges, pipe wrenches, dies, pipe

Two Alternating-current Motors on Adjustable Trucks and Rheostat with Bunks in Rear

fittings, nails, rubber gloves, disinfectants, stretchers, fire extinguishers, 2000 ft. of 2-in. fire hose, cooking utensils and tents. Eight Draeger helmets, two pulmotors, a large supply of potash cartridges and oxygen, safety lamps, gasoline, complete first-aid equipment, flashlights and lanterns are also provided.

TELEPHONES FOR RESCUE WORK

Another part of the equipment consists of eight portable telephones, equipped with one mile of twin conductor cable, made in accordance with the general specifications No. 548, of the U. S. Army, as follows: Each conductor is made up of seven wires of diameter 0.010 in., the center wire being of copper and surrounded by six steel wires, each conductor being insulated with 1/64-in., 30 per cent. rubber-compound braided conductor, laid parallel and covered with waterproof braid. The telephones are for use in rescue work and will make it possible for the rescue party to be in communication with the outside. A full set of blueprints of all the mines is kept on file in the helmet car. It is also provided with the tin pocket splints invented by W. V. Gage and described in our issue of Mar. 30.

The emergency car is worthy of more general adoption. The Consolidation Coal Co., in the Fairmont district, has a fan placed in a car, ready for transportation when needed, but the Colorado Fuel & Iron Co.'s outfit is more elaborate and more flexible and should do good work, if the company should be unfortunate enough at any time to have to make use of it.

When Welfare Work Fails

By CHARLES L. FAY*

There is welfare work and welfare work. There is the sort which is the result of sudden impulse, often requiring large financial outlay, a "big" scheme which looks well in print and then, like the beautiful sky-rocket having blazed forth its glory for the moment falls somewhere in the outer darkness. It is all over, another failure and one more well meaning enthusiast, its promoter, is turned into a pessimist.

This man who once felt the great inner joy of an endeavoring to do something for others less fortunate than himself, his own employees perhaps, now considers the rank and file of men ungrateful, without desire for self-improvement and utterly unworthy of further serious thought. I have heard men with similar experiences to that mentioned, say, after failing to thrust a pet plan upon the masses: "The more you do for people the less they respect you. I thought differently, I find I was a fool. I was deluded by a fancy."

*Mining secretary, Pennsylvania State Y. M. C. A.

NO WORK SHOULD BE SPASMODIC

It never occurs to that man that *he* was at fault. He fails to recall that he was guided by a *sudden impulse* which had no basis other than the honest desire of a naturally generous and sympathetic nature. The man was all right and the sudden impulse was good but something was needed to control and guide it. That man should have remembered first of all that men and boys, whether laborers, mechanics, or what not, *think, and they think in the sphere in which they live.*

They respond with sincerity to a real and practical effort in their behalf, but they rebel and turn away from the superficial scheme. No man can lift and hold another man's life to a higher plane than he himself lives upon. For motive is the real power whether that motive be right or wrong.

THE BERTILLON MARK IN WELFARE WORK

There have been instances where a man with humane desires but still dominated by a selfish motive, has projected a beneficent enterprise in an endeavor to develop employees or others to an unselfish plane of living and of conduct. The plan, of itself good, has failed to gain response from those it was intended to help and another pessimist results.

This man hides from his own consciousness a knowledge of his ulterior motive, boasts of his former willingness and desire to help other men and heaps invective upon the ungrateful (?) masses. The man of the "rank and file" felt instinctively the selfish motive lying far back in the recesses of that life which laid a bogus claim to a desire to "uplift him," and his manhood, latent and corroded, perhaps, rose in an unexpressed agony and resented the proffered aid. Had purity of aim graced an honest motive, that workman's manhood would have gradually risen in its majesty to the higher plane to greet its helper.

Strong impulse to do good, honest desire to better the conditions of men, pure motives in the enterprise on hand will always be backed by a careful study of conditions surrounding those to be benefited, also with a delicacy of perception and treatment which recognizes men as men.

The plan of helpfulness, thus born, whatever it may be, playgrounds, reading clubs, societies of one sort and another, will be so arranged that the genius of those gaining the benefits will be required and have ample opportunity to operate in maintaining and developing whatever is undertaken. So that, out of their lives may come a fruitage from the growth developing within, started and nurtured by the kindly spirit and honest motive of the benefactor.

A life is an outward growth from within; it cannot be lined with a tee-square and developed in a blueprint room. Qualities cannot be tacked to the character as an "addition" or a "cupola" is added to a house. Like a leaf or a flower it may be checked or controlled but its growth must proceed from the vital processes within.

Mine Rescue and First Aid Contest, Colorado School of Mines

SPECIAL CORRESPONDENCE

On the last day of March, a most interesting demonstration of the Draeger Oxygen Helmet in mine-rescue work, and a first-aid-to-the-injured contest, was held by the students of the State School of Mines at Golden, Colo., under Prof. J. C. Roberts, of the U. S. Bureau of Mines, who had Rescue Car No. 2 there for ten days while he, with the crew of the car, were giving instructions in the above work to about 80 students from the senior and junior classes.

In the first-aid contest, ten teams, consisting of a captain, four assistants and a patient, competed for a silver loving cup presented by Dr. Victor Alderson, head of the school. The judges were Captain George C. Osburne and two other U. S. Army officers.

The demonstration of life saving in mine fires or explosions, was given at the School of Mines' tunnel. Dense fumes poured from the portal; students wearing the oxygen helmets went in and rescued the victims, and then gave them first-aid treatment outside the tunnel.

For saving the lives of the workers in coal and metal mines such tuition is invaluable, and this fact is now recognized by mine operators all over the country, who are giving their employees free instruction in this great work. Professor Roberts was assisted by Professors Schneider and Allen.

Tree Culture

Without doubt the public schools are destined eventually to promote the desire for beauty which will make mine hamlets places of scenic charm and order.

It will be objected that children must be reckoned with in any plan of beauty culture. Children are fond of destroying trees, solely because this destruction forms an occupation for their waste activities, but it will be observed that they take up fiercely a defense of anything those same activities have created or fostered. Consequently if children be induced to plant trees they will be devoted in their defense of the beauty they have labored to create and if their interest is enlisted children are natural conservationists, as active in protection as they are otherwise prolific in devastation.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

A body of several hundred delegates, representing commercial organizations, and among them men from various coal mining bodies, notably the National Federation of Coal operators, met in Washington, Apr. 22-23, upon the invitation of the Secretary of Commerce and Labor, for the purpose of discussing the advisability of forming a national chamber of commerce which would represent the commercial bodies of the country and would give expression to their views and wishes in regard to matters affecting federal policy.

It was decided to form an organization of the kind and to ask for a national charter, to be granted by Congress, with the idea of giving the organization a certain amount of governmental recognition and standing which, it was supposed, could not otherwise be had. Four plans for organization were more or less urgently placed before the convention and the scheme finally recommended was based as far as possible upon the ideas embodied in these plans.

Secretary Nagel in his opening address indicated the necessity for such a body as this for the purpose of concentrating public opinion upon national questions, and enumerated some of the principal issues now pending before Congress as being among those with which it should deal. Harry A. Wheeler, of Chicago, chairman of the convention, stated his opinion that an important function of the enterprise should be to ascertain facts by investigation, and then to attempt to secure national action based upon the conditions thereby revealed.

The new organization will be national in scope and based on existing trade organizations, chambers of commerce, etc., each being entitled to a delegate if its membership numbers 50, with one additional delegate for every additional 100 members, the total number of delegates from any one organization not to exceed ten.

Coal Car Discrimination Cases

The Interstate Commerce Commission has made a series of important awards in the actions brought by the Hillsdale Coke Co., Jacoby & Co., the Clarke Bros. Co., and the Bulah Coal Co. against the Pennsylvania R.R., all of which involve the question of reparation for losses due to discrimination in the distribution of railroad coal cars.

Damages were awarded to the several coal companies and in explanation of its assumption of authority in this matter, the Commission states that "there is a conflict of view as between the Commission and the very court to which these complainants, if refused any relief here, would doubtless have to resort to secure a judgment for the damages here claimed to have been sustained. In order, therefore, to prevent a failure of justice in these cases, as well as to create an opportunity to secure a final ruling by the courts as to what should be our course of action in the future in such cases, we concluded to proceed with these claims; and having found that undue discriminations had been practiced by the defendant against the complainants, we ordered a reargument on the question of the amount of damages respectively sustained by them by reason thereof."

In closing the discussion, the Commission says:

Many theories as to the elements that should be considered in estimating damages in a case of this kind were advanced by each side. It is said by the complainants that their damages should be estimated on the basis of a supply of coal cars according to the physical capacity of their mines, or at least on the basis of their rated capacity. We have dealt with the claims only on the basis of the fair proportion of the available equipment that each claimant was entitled to receive in view of what we here find would have been a proper rating for each operation. According to the argument and brief on behalf of the defendant there is no sound theory upon which the damages of the complainants may be calculated. The defendant contends in all these cases that the coal which the complainants were unable to mine because of their failure to obtain their fair share of cars still remained in the ground, and that the extent of the damage really suffered cannot, therefore, be ascertained without proof, showing that the coal when subsequently mined was sold at a less profit than might have been realized during the period of the action. We are not prepared to enter upon a discussion of that question. Such claims are clearly justifiable, and we know of no better guide or basis for our action than the rule followed by the courts in similar cases.

Alabama

Odenville—The miners employed by the Seaboard Coal & Coke Co. went out on strike, Apr. 15, as a result of a dispute in regard to the method of payment. The men wanted payment on a yardage basis and the company proposed to maintain the present system.

Birmingham—According to official figures recently received by Chief Mine Inspector Nesbitt, Alabama jumped, last year, from sixth place to fifth place among the coal-producing states, despite the fact that the output for 1911 showed a reduction of over a million tons compared with 1910.

Colorado

Florence—The Colorado Fuel & Iron Co. is preparing to sink a new shaft about 1½ miles south of Rockvale on the Radiant branch of the Santa Fé. This will tap the most extensive coal area in the Fremont County field. At present this territory is being worked by the Canfield company, at Coal Creek.

Charles Cowan, formerly one of the county's large coal operators, has filed articles incorporating the Farmers' Progressive Coal Co., with a capital stock of $50,000 to operate coal mines in Delta County. Several years ago Mr. Cowan purchased a large tract of coal land near Paonia, which has been found to contain six seams of domestic and steam coal. The mine is situated on the mountain side overlooking the town of Paonia and a tramway, which is now being constructed to convey the coal from the mine to the foot of the hill, will land the coal within a mile and a half of the town.

Denver—The government brought suit some time ago to recover 4000 acres of coal land in Routt County, which it alleged had been obtained by fraudulent means through dummy entrymen. At the conclusion of the hearing of this case recently, Federal Judge Trieber advised the defendants that he would sustain the government, at least in regard to its claim to 1640 acres of the land.

Illinois

Murphysboro—At Bush, a mining village of 600 inhabitants, in Williamson County, 18 persons were killed by the storm which swept this section, Apr. 20. The town was laid in ruins, the property of the Western Coal & Mining Co., the post office, a store, two hotels and 40 dwellings were demolished.

Belleville—A jury in the circuit court recently awarded the Mulberry Hill Coal

Co. a verdict for $10,000, against the Illinois Central R.R. Co. as damages for failure to furnish the plaintiffs with coal cars for the transportation of coal during a period of 99 days. This is the first case tried in Illinois under the new law, and this is the third time the case has been tried. The railroad company will appeal to the supreme court.

Springfield—The Sangamon Loan & Trust Co. has been appointed receiver for the Barclay mine and will probably arrange to lease or operate the property while acting in this capacity

Condemnation proceedings in connection with the right-of-way for the extension of the Chicago & Northwestern R.R. to the coal fields of central Illinois are rapidly being wound up in Tazewell and Sangamon Counties and it is expected to have deeds to all the property desired, by the first part of May. The road passes through the counties of Tazewell, Mason, Menard, Sangamon and Macoupin. The expenses of securing the right-of-way through Sangamon County will amount to $300,000, while the aggregate for the other counties will reach $500,000.

Troy—It is reported that the well known Bennett coal mine, located about two miles west of Lebanon, will be abandoned in the near future. Practically all the available coal has been taken out and the underground haul is now too long to operate the mine profitably. The Bennett mine is one of the oldest in this section, having been operated for the past 40 years.

Indiana

Indianapolis—With the formal signing of the Cleveland wage contract here Apr. 25, by representatives of the United Mine Workers and the bituminous coal-mine owners, peace was established in the central competitive field, so far as wages are concerned, for the next two years. The field comprises Indiana, Illinois, Ohio and western Pennsylvania, and the agreement probably will be the basis for contracts in the North and Southwestern coal fields.

Terre Haute—The convention of Indiana United Mine Workers adjourned Apr. 19 for 10 days, to allow time for the signing of the interstate agreement. Linton was chosen as the place for holding the next biennial convention. The convention voted down the plan for mutual accident insurance, with the operators paying nine-tenths of the assessment, which would raise $235,000 a year, because the delegates want a state law which will establish compulsory liability for the operator.

Kansas

Pittsburg—Grievances that have been in existence for the past two months at mine No. 17 of the Central Coal & Coke Co. were settled recently by Vice-President Variot and Assistant Commissioner George Richardson. It is said that the agreement is eminently satisfactory to both sides.

Kentucky

Madisonville—Six lives are believed to have been lost in the explosion, followed by a fire, in the Coil coal mine, near here, Sunday night, Apr. 21. The body of Joseph Hollowell, the mine foreman, was found Apr. 23, and also the bodies of three negro miners.

Hickman—Representatives of the owners of coal mines of western Kentucky and eastern Tennessee have been here the past week trying to get men who have been flooded out of their homes and work to go to the mines to work. They have met with no encouragement, however.

Pineville — The New Straight Creek Coal Co., a corporation composed of Winchester capitalists which was organized for the purpose of leasing and operating the mines of the Big Hill Coal Co., at Blanche, has surrendered its lease, after having operated the property for about nine months. The Big Hill Coal Co., the owners of the property, took charge the first of the month and are now operating.

Winchester—Work on the opening of a new $100,000 coal-mining plant in the northern edge of Perry County, on the new extension of the Lexington & Eastern R.R., will be begun at an early date, and the owners, who are Northern capitalists, are arranging for headquarters here.

Ashland—Owing to the increased coal tonnage over its lines, the Chesapeake & Ohio is reported to be considering double-tracking from Russell to Ashland, and improving its facilities at Russell.

Henderson—The engine and boiler room of the Keystone Mining & Manufacturing Co.. at Henderson, was damaged by fire recently. The tipple was threatened by the blaze, which was kept under control, however.

A Chicago syndicate is reported to have acquired a considerable amount of coal lands along the Kentucky River, in Letcher County. It is on the right-of-way of the extension of the Lexington & Eastern Railroad.

Michigan

Saginaw — West side capitalists are back of a new coöperative coal-mining company which it is expected will be organized and incorporated in the near future. Twenty-five practical miners are wanted as stockholders. It is proposed to use the unworked part of the old Caledonia tract and add to it a large acreage. A shaft 900 ft. deep will be sunk. A vein 3 ft. 8 in. thick is to be found under this locality.

It is expected that all the men will be back at work in Michigan coal mines by the first of the month.

Ohio

Columbus—During a two-days' session, which adjourned at Columbus, Apr. 4, the executive board of the Ohio district, United Mine Workers, named the dates for holding a number of conferences between miners and operators in several of the sub-districts as follows: Massillon, May 1; Hocking Valley, May 6; Guernsey, May 9; eastern Ohio, May 15; Jackson, May 27. These meetings are for the purpose of perfecting the details of the Cleveland agreement. President John Moore will attend each of them and as soon as those named above have been held dates will be selected for holding similar conferences in the six other sub-districts in Ohio.

Bridgeport—Ten thousand miners in eastern Ohio resumed work Apr. 23, after being idle since the last day of March. The men were expected to resume work on the twenty-first, but for some reason they failed to get an official circular sent out last week, and refused to report. Miners at Plum Run, Bradley and Piney Fork, where rules which permitted pumpers and repair men to work pending scale conferences, were violated, are to be disciplined and many of the ringleaders will be expelled from the United Mine Workers.

Zanesville—The citizens of Winterset are greatly interested in rumors of the building of a new railroad running east and west through Guernsey County. It is said the new road will leave the Pan Handle at Coshocton, running east via Plainfield to Birds Run and Tyner, then passing through the coal fields of Harrison County and terminating at Jewett or Cadiz Junction. It is claimed that the new road will shorten the distance from Columbus to Pittsburg several miles and pass through one of the richest coal districts in the state. If the new railroad is built it is also rumored that new coal mines will be opened up.

Pennsylvania

Bituminous

Pittsburg — An award of reparation against the Pennsylvania R.R. Co., aggregating in five cases, $129,722, was made, Apr. 24, by the Interstate Commerce Commission. The commission found that the railroad had been guilty of unlawful discrimination in the distribution of its coal-car equipment, by reason of which five complaining coal companies had been unable fairly to market their products. The commission established a new principle by awarding damages in these cases. Heretofore, such matters have been referred to the courts

The orders require the Pennsylvania to pay to the Hillsdale Coal & Coke Co., $27,193; to W. F. Jacoby & Co., $21,094; to Clark Brothers Coal Mining Co., $31,-128; to the Bulah Coal Co., $31,716, and to James H. Minds, $18,592.

Efforts of socialists and those in sympathy with the Industrial Workers of the World to inject politics into the affairs of Pittsburg District No. 5, United Mine Workers, are said to have caused the present rupture in the ranks of the local district. An appeal, said to have the support of Michael Halapy, of Indianapolis, formerly of this city, to the national board, for a reëlection of officers of this district has been made. There is thought to be little chance, however, that the national council will grant the petition. Halapy was defeated for the presidency of the local district by Francis Feehan, of Pittsburg.

Thirty-five new men were placed at work, Apr. 23, in the mines of the Hicks Coal Co., of Brackenridge, in place of the miners who went on strike two weeks ago. The striking men contented themselves awaiting an adjustment of their difficulties. No disorder is expected.

Huntingdon—On application of the Broad Top Coal & Mineral Co., an injunction was issued, Apr. 22, by the Huntingdon County Court, enjoining certain members of the miners' union from interfering with the operation of the company's mines and trespassing on the company's property. The Broad Top company's mines have always been nonunion, and as a result of the recent organization of the miners, they have been closed down since Apr. 1.

Anthracite

Scranton—The sub-committee of anthracite operators and miners in session at New York reached an agreement, Apr. 25, and the coal companies are preparing for a resumption of work by Monday, May 13. The agreement will undoubtedly be ratified by the general committee, which meets on May 2, and also by the miners convention, to be held later, although some little dissatisfaction is felt among the men in not having obtained a higher increase in wages. Briefly, the terms of the agreement reached by the subcommittee are as follows:

A 10 per cent. wage increase, with the abolition of the sliding scale. A four-year contract. The granting of colliery committees, working in conjunction with union officials to adjust grievances, with the conciliation board as a final arbiter. The signing of agreements by the union executive officers as representatives of the Anthracite Miners' organization. The maintaining of laborers' wages at rates fixed by the strike commission of 1902. The right to elect checkweighmen and docking bosses at the collieries. The maintenance of the strike commission clause to pay all miners uniform wages, according to the 1902 settlement. The determination, by committees of miners and officials at each colliery, of what wage rates prevailed at the collieries prior to the 1902 strike, which formed a basis of the settlement of that controversy. A standard wage rate for miners employed on "consideration work." This rate has not been announced, but it is supposed to be $3.50 a day.

Four men were buried recently under a fall of burning culm, at the bank of the Central colliery, of the Pennsylvania Coal Co., at Avoca. The material was being washed away and, becoming undermined at a point near where the men were working, a portion which was on fire gave way and slid down upon them. All were rescued alive, but three of the men died later from their burns. Five men were seriously burned in the same way at this place about a month ago.

Wilkes-Barre—The annual meeting of anthracite mine inspectors opened in Williamsport, Apr. 24. Twenty-one inspectors from all over the region were present. D. J. Roderick, of Hazleton, presided over the gathering, and Carbondale, Scranton, Old Forge, Pittston, Wilkes-Barre, Hazleton, Mahanoy City, Shenandoah, Centralia, Pottsville, Lansford, Mount Carmel, Shamokin, Lykens and Forest City were represented.

Hazleton—The Lehigh Valley Coal Co. is moving the offices of the Hazleton division to the tenth floor of the new Markle Building, and combining with them the offices formerly at Drifton. In this way Superintendent Davies will have all his forces under his immediate supervision.

Tennessee

Bristol—According to a rumor that is current in Bristol and Roanoke, the general offices of the Virginia Iron, Coal & Coke Co. are to be removed to Bristol. The report is unconfirmed, but it is believed to have good foundation.

Coal Creek—A strike has been called at the Cross Mountain coal mine, of the Knoxville Iron Co., at Briceville. Sixty to seventy-five miners are out, pending a settlement of the matter. The strikers demand a 10-per-cent. increase in the wage scale, a 9-hour day and a semimonthly pay day instead of being paid off once a month, as heretofore. Inauguration of the strike was attended by no violence or demonstration of any character. President T. I. Stephenson, of the company, went to Briceville and was notified of the miners' demands. The company has made no public statement here as to what action it will take.

Washington

Tacoma—One miner was killed and seven were painfully but not seriously burned, as the result of an explosion of firedamp, Apr. 15, in the mines of the Pacific Coast Coal Co., at Burnett, a small coal-mining town 25 miles southeast of Tacoma. According to the superintendent, the explosion was caused either by the breaking of a miner's safety lamp or by the careless usage of one of the lamps.

West Virginia

Wheeling—A call was issued, Apr. 26, for a joint conference of the miners and operators of the Fifth Ohio subdistrict, which includes four counties in this state, to be held in Wheeling, May 15, to arrange the working scale for 17,000 miners. The operators asked to have the place of the meeting changed to Cleveland, Ohio, but the miners will not consent unless the operators agree to pay the extra cost of caring for the miners' delegates. The miners' annual convention opens here May 13.

Morgantown—Within a few days a new coal company will apply for a charter for the purpose of developing coal lands in Mineral County. Enough stock has been taken to buy 20,000 acres; at the present time 300 acres are owned by one of the men forming the new company. The capitalists composing the company are from Morgantown, Uniontown, Penn., and Baltimore.

Numerous mass meetings are being held by the miners, on strike in the Kanawha district. One at Smithers was attended by about 2000 men from the mines at Boomer, Harewood, Longacre, Cannelton, Carbondale and National.

The Mound Coal Co.'s mine, recently the scene of much rioting, followed by the arrest of a dozen strikers, resumed operation, Apr. 22, after a two weeks' suspension, and has continued to run with a gradually increasing force.

Charleston—Employees of two additional mines joined the strikers in the Kanawha field, Apr. 23—those at Peytona and Racine, along Coal River. About 300 men are employed there. The mines are nonunion.

Canada

Toronto—The commission appointed by the provincial government of Alberta to prepare amendments to the Coal Mine Act began its sittings recently in Calgary. John Sterling, provincial inspector of mines, has been appointed chairman. The government of Alberta proposes to establish several mining rescue stations at various points in the coal-producing areas. The first of these has been installed at Blairmore, where five men are now under training.

Japan

Tokio—Following an explosion of firedamp in the coal mine of the Hokkaido Coal Co. at Yubari, on the island of Yezo, Apr. 30, 283 miners were reported to have been entombed.

Personals

A. H. Storrs has been elected president of the Jed Coal & Coke Co., as successor to the late W. A. Lathrop.

J. F. Russell, sales manager for A. Simons & Son of Columbus, is confined in the Grant Hospital as the result of an accident.

Frank L. McCarty, formerly superintendent of the Union Pacific mines at Reliance, has been appointed superintendent of the Superior mines.

Carl Scholz, of Chicago, Ill., president of the Rock Island Coal Mining Co. and of the Coal Valley Mining Co., recently spent some little time in Birmingham, Ala., on business.

C. G. Weitzel, president of the New Pittsburg Coal Co., of Columbus, returned recently from Cleveland, where he went to investigate the outlook for the coming lake trade.

Edward N. Peterson, of Peoria, has been elected president of the newly organized Mid-Valley Coal Co., and William Noonan, of Tremont, has been elected vice-president.

Baird Snyder, Jr., formerly general superintendent of the Lehigh Coal & Navigation Co., Lansford, Penn., has opened offices in Pottsville, where he is established as a consulting engineer.

D. G. Thomas has been appointed superintendent of the Union Pacific mines at Rock Springs and Reliance. Mr. Thomas has been special inspector of the Union Pacific coal properties for the past two months.

H. H. Heiner, president of the Maynard Coal Co., which operates properties in the Pomeroy Bend field, Ohio, returned recently from a trip to the Pocahontas field, where he is interested as receiver for the Big Vein Pocahontas Coal Co.

William Leckie has resigned as manager for the Jed Coal & Coke Co., Jed, W. Va., and C. M. Kornuff has been elected as his successor. Mr. Leckie's resignation was tendered so that he can devote more of his time to other plants in which he is interested.

Edward H. Coxe, general superintendent of the coal mining department, Tennessee Coal, Iron & R. R. Co., who has tendered his resignation to take effect June 1, was recently presented with a handsome gold watch and fob by a party of his friends and business associates.

Lewis A. Riley has been elected president, *pro tem*, of the Lehigh Coal & Navigation Co., to fill the vacancy caused by the death of W. A. Lathrop. Mr. Riley was president for a short time prior to the election of Mr. Lathrop and has since been chairman of the executive committee.

Obituary

Harry R. Beeson, secretary-treasurer and sales manager of the New Pittsburg Coal Co., and one of the best known coal men in Ohio and adjoining states, died, Apr. 15, at his home in Columbus, after a three weeks' illness.

Mr. Beeson was born and reared in Pennsylvania. He was 45 years of age at the time of his death. Starting in as a clerk in the offices of the Hocking Valley R.R. Co., he later went with the Pullman company and subsequently became traveling auditor for the Emerson McMillan properties, widely scattered throughout the west. About 10 years ago he entered the employ of the New Pittsburg Coal Co. and rapidly rose to the position he occupied at the time of his death.

Construction News

Viper, Ky.—It is reported that the Kelly Coal Co. will build a coke plant.

Bastrop, Tex.—The Bastrop Coal Co. is sinking shaft No. 2 and will install additional machinery.

Phelan, Tex.—The Independence Mining Co. is sinking its No. 3 shaft and will install additional machinery.

Helena, Ala.—The Wadsworth Red Ash Coal Co., of Birmingham, contemplates developing coal mines near here.

Birmingham, Ala.—The Crescent Coal Co., B. F. Roden, president, contemplates opening a new mine, at Kimberly, at a cost of $100,000.

Florence, Colo.—The Colorado Fuel & Iron Co. has asked for bids for sinking and timbering a 400-ft. shaft about 1½ miles south of Rockvale, Fremont County.

Johnstown, Penn.—Announcement has been made that another mine will be opened at Foustwell by the Somerset & Cambria Coal Co. and a contract for a number of new houses will be awarded in the near future.

Pittsburg, Penn.—The board of directors of the Four States Coal & Coke Co. has recommended an increase of capital stock from $1,500,000 to $2,500,000 to provide for completing the equipment of Annabelle No. 2 mine and the development of another mine.

Hazard, Ky.—The Perry County Coal Co., capitalized at $400,000, will open and develop its property near Viper, Ky., including the Richmond-McIntire tract and adjoining lands. E. L. and A. G. Speaks have organized the Speaks Coal Co., to develop a leased mining property.

Hazleton, Penn.—The Dodson Coal Co. contemplates improvements at the Morea colliery which will involve machinery for handling mine cars to and from a dump supplying a gunboat hoist in the mines. Address inquiries to T. M. Dodson, vice-president, Morea Colliery, Penn.

Birmingham, Ala.—The Sloss-Sheffield Steel & Iron Co. will expend $50,000 for mine improvements, to include 400 hp. increase of boiler capacity and two air compressors at the Bessie coal mines and a 300- to 400-hp. boiler increase at the Flat Top coal mines, costing $15,000, and improvements at Sloss iron-ore mines costing $35,000.

Publications Received

THE COAL MINER. A STUDY OF THE STRUGGLE TO SECURE REGULATED WAGES IN THE HOCKING VALLEY. By Earl A. Saliers, Ph. D., Instructor in Economics in Lehigh University, South Bethlehem, Penn. Bethlehem Printing Co., 1912. 1¼x 7¾ in. 65 pp., no illus. Cloth. $1.

In view of the sub-title of this book, it is not necessary to point out that the writer has taken almost without exception the standpoint of the miner. But we must concede he has shown a conservatism of statement and a dignity of language which will make the book acceptable reading to those who view the controversy from a different standpoint.

In the first chapter he discusses the "Pre-organization Period" when the Hocking Valley coal field was in its infancy. He details the disturbances which followed the unreadiness of the operator to recognize the inability of the Hocking Valley furnaces to cope with the competition of those in the Alabama fields. Realizing that the market was being destroyed by competition, they strove at first to lower wages but ultimately met the original wage by invading new markets. In the second chapter is discussed the "Period of Organization" and interesting but brief information is given of the earlier unions and of the formation of the United Mine Workers of America.

The third and last chapter discusses the evils of the "Truck System of Payment" and of delayed pay, and records the legislation, often ineffectual, by which it was sought to control and restrain these developments. The book can be read in one sitting and while unsensational, treats a mass of details in an interesting way. As the writer omits all statistics, one cannot form from the book itself an estimate of the truth of his conclusions. However, if the figures were obtained, it is probable that they would substantiate all that the author has stated.

Trade Catalogs

Helmick Foundry-Machine Co., Fairmont, W. Va. Booklet. Helmick Mine Cars. 15 pages, 3½x6 in., illustrated.

Ingersoll-Rand Co., 11 Broadway, New York. Bulletin. "Arc Valve" Tappet Rock Drills. 16 pages. 6x9 in., illustrated.

Chain Belt Co., Milwaukee, Wis. Monthly Bulletin. Concrete and Chain Belt Concrete Mixers. 8 pages, 6x9 in., illustrated.

Goulds Manufacturing Co., Seneca Falls, N. Y. Booklet. How and Where Pumping Costs Can be Reduced. 16 pages, 6¾x8¼ in., illustrated.

Industrial

The H. Koppers Co., of Chicago, announces that it has succeeded to the business of H. Koppers, of Joliet, Ill., and will soon establish general offices at No. 5 Wabash Ave., Chicago. Mr. Louis Wilputte, formerly connected with the business of H. Koppers, is not connected with the new company.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The stocks accumulated in anticipation of a prolonged suspension at the mines are having a decidedly depressing effect on the trade, with the result that the market is dull and heavy. Prices have been easing off slowly but steadily for several weeks, and buyers are hesitating to enter the market until satisfied that the bottom has been reached. Supplies are so plentiful that some consumers are offering to dispose of their surpluses.

In the Eastern markets no effort is being made to obtain anything more than a normal price; that is, last year's quotations with the new wage scale added. Some companies are still delivering on contracts made at the high level prevailing through March, but this business will soon close. It is rumored at some points that the selling scale fixed by the Pittsburg companies is being severely cut. Mines in that district are only working about 50 per cent. capacity, most of the operators refusing to open up full blast until there is some pressure for coal. Supplies of anthracite are down to a low point, and a continuation of the suspension at the mines will soon result in an acute shortage in this branch.

Prices in Ohio and West Virginia are soft, except in the small sizes, which are in good demand. Most of the Ohio mines are now in operation, and a heavy lake trade is anticipated during the coming season. It is expected the April shipments to the coast from West Virginia will break all previous records, and while the market generally is not so active, the demand is still fairly strong.

The trade in the Middle West is nearly demoralized. There is an almost total absence of any buying movement, large supplies are still in evidence, and the operators are seeking an increase in prices to compensate for the increase in the mining scale. A large number of mines are opening up, and should the output be heavy, prices will probably drop to about the cost of production.

Boston, Mass.

Some inquiry for contract has developed lately in bituminous, but there is little interest in coal for current needs. Stocks accumulated during the "flurry" are surprisingly large, and together with mill suspensions here and there and an unusually heavy run of water for power makes the outlook rather dull. There appears to be a disposition on the part of the Pocahontas and New River interests to net more remunerative prices than obtained last year and with conditions here as they are that would certainly point to a slow druggy market through the spring and early summer.

In Georges Creek and the Pennsylvanias there is no material change. There is no longer an effort to get any but normal prices, that is, last year's level with the increased mining cost added. At that the movement is light into New England.

Marine freights are down to 70c., Hampton Roads to Boston, and in most cases tonnage goes begging. The release of certain anthracite transportation for soft coal has reduced the rates that previously held from Philadelphia.

Bituminous in transit all-rail has been practically cleared up. The resumption in the union districts means that buyers' wants can now be easily and promptly supplied.

The news of the compromise in anthracite has allayed any fear of a prolonged tie-up. With retail prices still where they were put to stop undue buying early in March, there is little coal going out to the consumer. One large retailer speaks of his delivery yard being turned into a horse show.

Quotations are as follows:

Clearfields, f.o.b. mines	\$1.15@1.35
Clearfields, f.o.b. Philadelphia	2.40@2.60
Pocahontas, New River, f.o.b. Hampton Roads	2.75@2.80

New York

The New York market is dull and quiet. Prices have been steadily easing off for several weeks and are now at the lowest point reached since the panicky conditions in effect during the early part of the suspension. At no time has there been any acute shortage, although rumors to that effect resulted in a heavy buying movement on a number of occasions and caused prices to advance sharply. There are adequate supplies on hand now and the market is about normal.

The low-grade bituminous coals are being quoted down as low as \$2.50 or \$2.55 f.o.b., but there is not much offering at this price. The higher grades are nominally about \$3 f.o.b., although there are few transactions being made. The movement is confined principally to shipments on contract, and there is little demand for spot coal. Mines shipping this market are working up to a good capacity, and large tonnages are coming in.

In anthracite the situation is not so easy. The effects of the long shutdown at the mines are being felt, and while the prospects of a settlement are now in sight, it will be some time before any shipments can be expected, and there is a noticeable uneasiness among consumers. A joint meeting of the operators' and miners' full committees takes place here, May 2, to consider the results of the agreement reached by the subcommittees. It is generally believed that a resumption will not be effected before May 15, or possibly June 1.

The following are the prices nominally quoted, although any actual buying brings a premium on these:

Broken	\$4.50
Egg and stove	5.00
Chestnut	5.25
Pea	3.25
Buckwheat	2.75
Rice	2.25
Barley	1.75

Philadelphia, Penn.

It looks now as if peace between the miners and operators was about to be concluded. There is no doubt that some sort of arrangement has been made between the sub committees which will in due course be submitted to the committees of the whole, and it will be simply a matter of form to have favorable action passed on their findings by the several representatives of the operators and miners. Concessions on both sides have doubtless been made, and more than likely the middle of May will find the miners back to work under the new arrangements. This is further borne out by the fact that it is understood that the wholesale people are receiving numerous inquiries for prices, and while none are quoted, there seems to be a disposition to inform the dealers that the next week or ten days will see a basis of prices established for the coming season.

Of course, it is useless to speculate what the prices will be when announced. The chances are very much in favor of an advance over last year for some of the sizes, probably stove and pea. There may be a general advance all along the line in the domestic sizes, most if not all of the companies having practically all their output of the smaller sizes covered by contracts entered into the beginning of the year. These were \$1.75 for pea, \$1.25 for buckwheat and 85c. for rice. Car-

load lots may bring more than these prices, but the companies as a rule are almost covered up to their normal output of these small sizes and there is little to be had.

The retail trade in this vicinity is practically *nil*. Springlike weather has caused many fires to be drawn, and most householders are able, by sweeping up the corners, to accumulate sufficient to carry them over the few cool days which appear.

Pittsburg

Bituminous—The mines are opening rather slowly, demand being light. While the formal opening occurred the beginning of last week, in the early part of this week the mines in the Pittsburg district are probably not operating 50 per cent. of full capacity. Consumers are still using stocks and it is quite clear that one of two things was the case: Either consumers laid in too large stocks, or the operators reached a settlement with the miners too quickly. As the operators profited by the stock up, which advanced the market very materially and furnished an excellent tonnage, they are not disposed to complain of the stocking, and are endeavoring to avoid trouble from the scale being adjusted too quickly, by refraining from opening their mines until there is pressure for coal.

A definite effort will be made to hold the market on the basis announced in our report last week, \$1.22½, against \$1.15 a year ago, even though the \$1.15 price was not uniformly maintained and the 7½c. advance more than covers the advance in the wage scale. Thus far the market has not been seriously tested, demand being so light, but we do not hear of any cutting.

Shipments in the lake trade will start Wednesday, May 1, when the freight rate goes from 88 to 78c., but they will be light at the start, and entirely on old contracts. There is still negotiation on new contracts and the parties are not getting together very rapidly. We quote: Mine-run and nut, \$1.22½; ¾-in., \$1.32½; 1¼-in., \$1.47½; slack, 82½c. per ton at mine, Pittsburg district.

Connellsville Coke—Production and consumption are adjusted very closely, and the market is inactive. We note a sale of 10,000 tons of furnace for May delivery, at about \$2.50, ovens, which about represents the market. Furnaces are in a comfortable position at present, but many will need to contract for second half, having contracts at \$1.55, \$1.60 and \$1.65 which run out June 30. As a rule these furnaces cannot afford to pay \$2.50, considering the price of pig iron and the question is whether sufficient demand will develop to cause more furnaces to blow in. They would only come in at higher pig-iron prices, which would justify the higher price for coke. We quote: Prompt furnace, \$2.50; contract (nominal), \$2.25; prompt foundry, \$2.75; contract foundry, \$2.40@2.50, per ton at ovens.

The *Courier* reports production in the Connellsville and Lower Connellsville region in the week ending Apr. 20 at 396,320 tons, a gain of 33,000 tons, and shipments at 4129 cars to Pittsburg, 6403 cars to points West and 1122 cars to points East, a total of 11,654 cars, or an increase of 621.

Buffalo, N. Y.

There is still very little life in the coal trade. Anthracite will return to its own in a short time, with the trade in excellent shape, and with conditions the best for a profitable season, but there is very little that is hopeful in the bituminous outlook. The operators are eager to give to the consumers not only every advantage offered them, but even more. A scale of prices has been made by the leading Pittsburg companies, but it is already reported that it has been cut pretty badly, with the exception of slack, which appears to be strong everywhere. This is largely due to the fact that the lake trade is backward and not much slack has been made.

All the wage scales at mines tributary to this market have now been settled, and the miners are to get 3c. or more increase in pay, but it does not appear that the mine owners will profit much by the new scale, unless it may be in the case of the anthracite interests. At least there has been no selling of coal in April at the usual reduction and the rumor that the new scale will be advanced is still very persistent and will no doubt eventually materialize.

The Canadian coal situation was much affected by the congestion of rail traffic before the mines shut down. At that time there was coal, mostly bituminous, side-tracked everywhere, waiting for motive power to move it. This coal is now being delivered and it affects present sales seriously. When it is all in, some of the consumers will have a year's supply on hand. There are so many conditions favoring a slow bituminous market that not a few of the mine owners are holding off or starting only in part in order to meet some regular order or contract.

The lake trade is now on and there is soft coal loading at Erie and Ohio ports, but there is no anthracite for that trade anywhere. It was claimed that there was a large stock of anthracite held at various points, waiting release as soon as the mining scale should be fixed, but this is denied by shippers. They were just able to satisfy their regular trade when the suspension took place so that it is practically impossible that any important surpluses could have been accumulated at that time.

Bituminous prices for this market are nominally \$2.57½ for Pittsburg three-quarter, \$2.47 for mine-run and \$2.10 for slack, with coke hardly so strong as formerly at \$4.75 for best Connellsville foundry. Most prices are weak and the market is very unsteady generally for bituminous sizes. There is every prospect of the supply exceeding the demand considerably.

Baltimore, Md.

While there was a somewhat better demand for coal in the Baltimore market during the past week, it was not sufficient to affect prices in the least. Low-grade coal is now quoted around 80 and 90c., while the second best grade is bringing \$1.10, and the best big vein \$1.65 per ton.

There is no rush for the product, and consumers find not the slightest difficulty in getting all the fuel they want at greatly reduced prices. Many of the Baltimore operators are still delivering under contracts closed in March, but these deliveries will probably be completed by the end of next week. The trade is quick to admit that it will be some time before contracts are closed at any such figures as those given by consumers, who were willing to pay anything for their supply rather than be caught short in case of a prolonged strike. The sentiment in Baltimore is that there will not now be a serious strike in the United States for many years to come.

It was pointed out in the past week that before the time for the next wage-scale conferences arrives, the Erdman act will have been amended so as to include coal fields as well as the railroads. In the event that the act is so amended, meditation can be resorted to, should the miners and operators be unable to reach a satisfactory agreement between themselves.

Some indication of just how active the demand was during March, while the English strike was in progress and labor troubles threatening here, is given by the statement of coal tonnage handled by the Baltimore & Ohio R. R. for that month. The total tonnage was 3,173,168, as compared with 2,027,245 for the same month of 1911, making a gain of 1,145,-923 tons for March of this year. The coke tonnage for the month shows a decrease, the total for March being 384,094 tons, as against 371,219 tons for the corresponding period of the preceding year.

The Consolidation Coal Co. will, in all probability, begin the shipment of coal from its new mines in the Elkhorn Valley of Kentucky some time in June. The new railroad which this company is building is nearing completion, and will be operated by the Baltimore & Ohio R.R. Company.

Columbus, Ohio

The coal trade in Ohio is in a state of anticipation. Since the mining scale was formally signed by the operators and miners, everyone engaged in the trade is looking forward to considerable activity. While there is a pretty fair stock of coal in certain sections, everything indicates a rather active season and preparations are being made accordingly.

The majority of Ohio mines will resume operations May 1, although some have been in operation during the past week in eastern Ohio. In the Hocking Valley the New Pittsburg Coal Co. had several mines in operation by Apr. 22.

Quotations in Ohio are soft, excepting in the small sizes, which are the strongest feature in the trade. There is a good demand for both nut, pea and slack and coarse slack and this will probably continue until the lake trade becomes active. Jobbers having nonunion connections have been placing a small tonnage in central Ohio, although most of the railroads and many of the manufacturing establishments are stocked until the latter part of May.

Great results are expected from the lake trade this season. Preparations are being made to ship a large tonnage from Ohio mines to the Northwest, as there is practically no coal being carried over on the docks. The reduction by the Pittsburg Coal Co. of the dock price from \$3.50 to \$3.40 is expected to have a considerable effect on lake conditions. The jobbers in the Northwest are asking that the 10c. be taken off the price at the mines in order that they can compete with the Pittsburg Coal Co. There is still considerable ice in the upper passages and little coal will be moved in that direction until the middle of May. A number of lake boats will be loaded, however, previous to that time, to be moved as soon as insurance is obtainable on boats and cargoes.

Prices which prevail in the Ohio fields are:

Hocking Valley	
Domestic lump	\$1 50
¾-in	1 35
Nut	1 20
Mine-run	1.10
Nut, pea and slack	0 90
Coarse slack	0 80
Pittsburg No. 8	
¾-in	\$1 30
Mine-run	1 10
Coarse slack	0 80
Pomeroy Bend	
Domestic lump	\$1.60
¾-in	1 40
Nut	1 25
Mine-run	1 15
Nut, pea and slack	0 95
Coarse slack	0 85
Kanawha	
Domestic lump	\$1 50
¾-in	1 30
Mine-run	1 10
Slack	0 80

There is some stir in domestic circles, but little is expected in that direction until after June 1. Some inquiries are being received for the fancy grades, such as West Virginia splints and the rescreened grades. Dealers are carrying some stocks over.

Hampton Roads, Va.

While the market is not nearly as strong this week as it has been during the past six or eight weeks, there is, nevertheless, a heavy demand for Hampton Roads coal. In fact, up to the present time the month of April has broken all previous records in the way of shipments from the piers at Lamberts Point, Sewalls Point and Newport News, the Norfolk & Western piers at Lamberts Point leading the other two by a good margin. For the first 18 working days this month they dumped on an average of 21,666 tons a day.

Work has commenced on the new Norfolk & Western piers and with improved conditions both here and at Newport News, Hampton Roads gives promise of becoming the leading coal center in the world. The Chesapeake & Ohio Ry., in testing out one of their new Mikado engines, on Thursday, pulled 110 steel coal cars from Richmond to Newport News in approximately five hours. They are putting several more engines of this type into commission and while they will not be called upon to carry such a load upon every run, this class of equipment is a long step in the way of better movement on tidewater coal.

There are still a number of vessels, foreign and American steamers, schooners and barges anchored in the Roads awaiting berth to load cargoes of coal. Indications are now, however, that these hold-overs will be disposed of within the next week. The local coal market still continues steady with prices on spot coal ranging from \$2.75 to \$3.

Charleston, W. Va.

With two-thirds of the mines in the Kanawha district closed down on account of the strike and with both sides playing for position there has been no important change in conditions over those prevailing a week ago. Despite the fact that little coal is being shipped there has been no increase in the price.

Detectives have arrived to guard the property of the coal companies in the event of trouble, and also for the purpose of ejecting the miners if they refuse to return to work at the old terms and conditions. Up to the present time, however, the companies have not ordered the men from the houses, but this is one of the moves expected every day and when it is taken trouble will follow that will doubtless require the calling out of the militia.

The strike has had no effect in the New River and Pocahontas districts, nor are any mines reported closed in the Fairmont region. There are a few mines out, however, along the Ohio River section, in the northwestern portion of the state.

The car supply has been good and selling agencies have been busy trying to sell coal at prices that are considered fair, but not the figure that was believed would prevail with so many mines closed.

Louisville, Ky.

The warm weather and fine boating stages have had the effect of solving the strained situation which existed in connection with the local coal supply. The only inconvenience caused was in domestic. Now that the threatened coal-mining troubles have practically disappeared, those who were storing coal for emergency uses, especially the railroads, are letting it go. The heavy shipments by water from the Pittsburg district are also helping to establish normal retail prices for this time of the year. The local dealers are advertising reduced prices as an incentive for customers to lay in a supply for next winter.

Indianapolis

Only a few Indiana mines were reported to be in operation during the week. Mines operated in connection with manufacturing concerns were permitted to work, but those in southern Indiana, producing coal for railroads, were ordered to cease operations when it was found they were hauling coal to the general market.

The retailers are booking orders for immediate shipment to fill their summer storage orders when the mines resume operations. The mine operators say that improvements to their plants are about completed, and that the mines will be found in first-class condition when operations begin, which is expected in a few days.

Chicago

According to indications, the Chicago market will witness little buying for another month. A number of big consumers have cars of coal on their sidings which they are willing to sell to other consumers if the latter would offer a fair price.

Chicago dealers have been advised that the Ohio mines have arranged to add 5c. to last year's contract figures. The Indiana mines have added 7c. a ton to the old contract prices on mine-run and screenings and 10c. on lump coal. It is believed that this price will hold. The Illinois producers say that they will be obliged to add 12½c. a ton to last year's prices in order to come out even.

Prices of coke have been marked down. The furnace and foundry cokes have been

held at a rather stiff figure, in anticipation of a strike. These prices could not hold through the present period of dullness, and there has been a shading of values.

Prevailing prices at Chicago are:

Sullivan County:	
Domestic lump	$2.62@2.87
Egg	2.50@2.75
Steam lump	2.17
Screenings	1.67@1.82
Springfield:	
Domestic lump	$2.57@2.82
Steam lump	2.17
Mine-run	1.97@2.07
Screenings	1.67@1.82
Clinton:	
Domestic lump	$2.52@2.77
Steam lump	2.17
Mine-run	1.97@2.07
Screenings	1.67@1.77
Pocahontas and New River:	
Mine-run	$3.15
Lump and egg	4.05

Coke—Prices asked for coke are: Connellsville and Wise County, $4.75; byproduct, egg and stove, $4.55; byproduct, nut, $4.55; gas-house, $4.75.

St. Louis, Mo.

There is practically no change in the St. Louis coal market, as there has been little or no demand. The latter part of last week a few of the mines in the Standard field opened up, the first of these being the mine at Nashville, Ill., on the L. & N. R.R.

The Standard market opened up with 2-in. lump coal selling at from $1.15 to $1.25, and screenings from 90c. to $1. A few of the Carterville mines opened up, but there is very little demand for the coal, and it is being offered at from $1.25 to $1.40 for the lump, egg, and nut.

It is almost impossible to say what the developments will be before the present week is over, but indications are that prices will go down to about the cost of production, as there is no market, and the producers will try to operate their mines regardless of conditions.

Portland, Ore.

Nothing new or startling has developed in the coal trade in this district for some time and business is barely normal, owing to the fair condition of the weather. Receipts by rail have been ordinary in volume with very little coming in by water. No more Australian coal will arrive here until next fall and the stock on hand is quite sufficient to meet all demands. The demand for coal the past winter was lighter than usual on account of mild weather and keen competition from wood dealers. Prices remain unchanged.

Production and Transportation Statistics

Shipments to Our Non-contiguous Possessions

Alaska—Fuel shipments to Alaska for February of the present year amounted to 2244 tons as compared with 1341 tons during the same month last year.

Porto Rico—Total shipments of bituminous coal to Porto Rico during February of the current year amounted to 4555 tons as compared with 6165 tons during the same month last year. No anthracite was shipped to Porto Rico during February of last year, and only 101 tons this year.

Consolidation Coal Co.

During the year 1911, the Consolidation and its subsidiary companies mined 8,231,903 tons of coal, and made 43,740 tons of coke. The coal mined by lessees amounted to 473,008 tons.

Baltimore & Ohio Railroad

The total tonnage hauled over the lines of the Baltimore & Ohio for the month of February was 2,695,874 tons as compared with 1,701,846 tons for the corresponding month of 1911, making a gain for February of this year of 994,028 tons.

Atlantic Coastwise Movement

Comparative statement of fuel shipments, in long tons, from five principal Atlantic ports for February, 1911-12, including bunker coal placed on vessels in the domestic and foreign trade and comprising probably 90% of the total shipments from these points.

	1911	1912
New York	1,867,893	2,470,043
Philadelphia	526,422	412,011
Baltimore	356,601	286,085
Newport News	233,685	237,682
Norfolk	267,300	428,036
Total, 5 ports	3,251,901	3,833,857

Government Coal Contracts

Western Division — Sealed proposals will be received until 11 a.m., May 10, 1912, for furnishing fuel required at the posts of the Western division during fiscal year commencing July 1, 1912. Prospective bidders should address Post Quartermasters or Quartermasters at Seattle, Wash., and Portland, Oregon.

Eastern Division—Sealed proposals in triplicate for furnishing coal required in the Eastern division during year ending June 30, 1913, will be received until 10 a.m., May 15, 1912. Bidders should address Chief Quartermaster, Governors Island, New York Harbor.

Pacific Coast — Sealed proposals in duplicate will be received until 11 a.m., May 24, 1912, for furnishing fuel for the fiscal year beginning July 1, 1912, at Bear Island, Calif.; San Francisco, Calif., and Bremerton, Wash. The right is reserved to reject any or all bids or parts thereof and waive informality therein. Bids from regular dealers only will be considered. Prospective bidders should address the Depot Quartermaster, Marine Corps, 182 Second St., San Francisco, Calif., or the commanding officer or Post Quartermaster, Marine Barracks, at the station named.

Norfolk & Western Ry. Co.

Comparative statement of coal and coke shipments over the lines of the N. & W. Ry. Co. for March, 1911-12, was as follows, in short tons:

Destination	1912	1911
Coal		
Tidewater, foreign	146,089	90,488
Tidewater, coastwise	286,340	236,233
Domestic	1,353,330	980,033
Coke		
Tidewater, foreign	8,859	5,117
Domestic	140,298	163,141
TOTALS	1,934,916	1,475,012

Financial Notes

The O'Gara Coal Co. reports for the fiscal year ended Oct. 31, 1911: Gross earnings, $3,671,460; net profit, $335,171; surplus for year, $283,810; total surplus, $568,522. The company has $1,000,000 of 5% preferred stock, $5,000,000 of common and $3,000,000 of bonds. The company operates mines in Saline County, Ill.

Confirmation of the report now in circulation that the preferred dividend of the Pittsburgh Coal Co. will be increased from 5% to 7% annual basis cannot be confirmed in official quarters. It is stated that the matter has not been discussed by the board and that such increase is not contemplated at the present time.

General expenses and fixed charges of the Lehigh Coal & Navigation Co. for the year ended Dec. 31, 1911, were $432,610 for taxes; interest on funded debt was decreased $101,605, chiefly by retirement of the consolidated mortgage 7s. Against this latter was a full year's interest on the collateral trust 4½% loan issued Nov., 1910, making a net decrease in interest on funded debt of $35,980.

The coal-mining department of the Delaware & Hudson Co., which forms a considerable part of the company's business, brought in but a small amount of profit directly. On a gross business of $13,355,000 only $116,000 remained as net profits and, after paying taxes on the property, there remained a deficiency for the year of $24,000. Last year the mining profits were but $42,000 on $11,806,000 worth of coal sold.

The Pittsburgh Coal Co., after carrying to credit of undivided earnings account the net earnings for the year and charging the four dividends of 1¼% each or 5% on the preferred stock outstanding ($1,353,590), the amount to its credit Dec. 31, 1911, was $8,481,541 (an increase of $38,347 over 1910). There has been no readjustment in the values of any of the assets sustaining this credit, and they are believed to represent a greater worth than they are carcarried at, not including coal rights which are largely in excess of book value.

The directors of the Island Creek Coal Co. will probably place the 100,000 shares of common stock on a dividend basis of $3, beginning with the coming October. The current year is expected to show output of between 2,000,000 and 2,200,000 tons of coal as compared with 1,876,000 tons mined during the fiscal period of Dec. 31 last. At prices which the company is getting for its coal additional $250,000 more may be figured for the common stock above the $2.34 secured in last year. This means that the common stock will this year earn close to $500,000 against $233,357 in 1911.

Index of Coal Literature

Monthly list of the world's best articles on coal and coal mining

The following is a list of abbreviations used below:

A.E.G.-Ztg. = A.E.G.-Zeitung.
Ann. Mines = Annales des Mines.
Ann. Mines Belgique = Annales des Mines de Belgique.
Berg-Hüttenmänn. Rdsch. = Berg- und Hüttenmännische Rundschau.
Bull. Am. Inst. Min. Eng. = Bulletin American Institute of Mining Engineers.
Bull. Assoc. Ing. Liège = Bulletin de l'Association des Ingenieurs sortis de l'Ecole de Liège.
Bull. Ass. Sucr. = Bulletin de l'Association des Chimistes de Sucrerie et de Distillerie de France et des Colonies.
Can. Eng. = Canadian Engineer.
Chem. Eng. = Chemical Engineer.
Coll. Guard. = Colliery Guardian.
Compt. Rendus Acad. Sc. = Comptes Rendus de l'Académie des Sciences.
El. Eng. = Electrical Engineering.
El. Jl. = Electrical Journal.
Eng. Contract. = Engineering Contractor.
Eng. Min. Jl. = Engineering and Mining Journal.
Eng. News = Engineering News.
Geol. Mag. = Geological Magazine.
Giess.-Ztg. = Giesserei-Zeitung.
Iron Coal Trades Rev. = Iron and Coal Trades Review.
JB. Berg-Hüttenw. Sachsen — Jahrbuch für das Berg- und Hüttenwesen im Königreich Sachsen.
Jern. Kont. = Jern Kontorets Annaler.
Jl. Soc. Chem. Ind. = Journal of the Society of Chemical Industry.
Jl. Gasbeleuchtung = Schilling's Journal für Gasbeleuchtung und Wasserversorgung.
Jl. Royal Soc. Arts = Journal of the Royal Society of Arts.
Jl. S. Afr. Inst. Eng. = Journal of the South African Institute of Engineers.
Kohle Erz = Kohle und Erz.
Mines Minerals = Mines and Minerals.
Min. Sc. Press = Mining and Scientific Press.
Min. World Eng. Rec. = Mining World and Engineering Record.
Mitt. Ver. Moorkultur = Mitteilungen des Vereins zur Förderung der Moorkultur im Deutschen Reich.
Mon. Ind. Gaz = Moniteur de l'Industrie du Gazet de l'Electricité.
Montan. Rdsch. = Montanistische Rundschau.
Oesterr. Tonind.-Zeitung — Oesterreichische Tonindustrie-Zeitung.
Oesterr. Z. Berg- Huttenwes. — Oesterreichische Zeitschrift fur Berg. und Hüttenwesen.
Rev. Noire — Revue Noire.
Rev. Univ. Mines = Revue Universelle des Mines.
Rock Prod. = Rock Products.
S. Afr. Min. Jl. = South African Mining Journal.
Stahl Eisen = Stahl und Eisen.
Stein-Braunkohle — Stein und Braunkohle.
Tech. Rdsch. = Technische Rundschau.
Trans. Inst. Min. Eng. = Transactions of the Institution of Mining Engineers.
Trans. Manchester Geol. Min. Soc. — Transactions of the Manchester Geological and Mining Society.
Ung. Mont. Ind. = Ungarische Montanindustrie und Handelszeitung.
Z. El. Mach. = Zeitschrift für Elektrotechnik und Maschinenbau.

Note: We shall be glad to obtain for readers, where possible, copies of the papers referred to.

I—GENERAL

Coal on Vancouver Island, B. C. E. Jacobs, Can. Min. Jl., Vol. 32, 1911, 24, pp. 807-8.

The World's Coal Production. Coal Age, Vol. 1, 13, pp. 398-400, 2 fig. (A synopsis of available statistics and notes on different fields.)

World's Coal Production and Consumption. Iron Coal Trades Rev., Vol. 83, 1911, 2287, pp. 1057-8, 8 tab.

The Mining Year Book 1912, 8vo. Financial Times, London, $3.75, net.

Coal and Coke Exports in 1911. Coal Age, Vol. 1, 13, p. 417. (American Export has trebled in 12 years, now amounts to 80 million dollars.)

The Colliery Guardian Review of the Coal Trade in 1911. Edit. by H. Greenwell, 8½x5½, 161 pp., 8vo. Colliery Guardian, London, 25c., net.

Scientific Coal-Mine Management. Sim and W. H. Reynolds, Mines Minerals, Vol. 32, pp. 459-60, 2 tab. (Three devices by which accurate knowledge of working conditions can be had daily.)

Notes on Mine Accounting. T. H. Sheldon, Eng. Min. Jl., Vol. 92, 1911, 26, pp. 1231-2.

Minimum Wage Boards. F. Kelley, Am. Jl. Sociology, Vol. 17, 3, pp. 303-14.

Treatise on the Law and Practice relating to Letters Patent for Inventions. R. Frost, 2 vols., 4th Edtn., Ryl., 8vo., Stevens & Hall, London, $9.50.

Western Coal Land Legislation. Mines Minerals, Vol. 32, 1911, 5, pp. 277-8. (System of leasing to avoid long time speculative investment. Present coal land laws.)

The Mining Law. H. V. Winchell, Min. Sci. Press, Vol. 104, 10, pp. 366-70. (The faults of Canadian and United States mining laws, and suggestions for changes. A comparison of English and American systems. The fundamental differences in the concession systems of South Africa and Australia. Claim systems, American regalian right.)

The Smokeless Coal Field of West Virginia. Edwin Ludlow, Mines Minerals, Vol. 32, pp. 467-8, 1 tab. (Legal and business conditions which operate to promote the wasteful exploitation of coal lands.)

American vs. English Mine Fatalities. J. T. Beard, Coal Age, Vol. 1, 13, pp. 403-5, 1 tab. (American output per man double that in England. Pennsylvania death rate lower than Great Britain's. Conditions in American mines.)

Fatal Accidents in Mines in 1911. Colliery Guard, Vol. 103, 2664, pp. 128-9.

Coal Supply and Coal Prices. (Kohlenversorgung und Kohlenpreise.) Konjunktur, 1911, Vol. 3, 11.

Price Policy of the Coal Syndicate. (Die Preispolitik des Kohlensyndikates.) Konjunktur, 1912, Vol. 3, 16.

The Technical Features of the Sale of German Coal in Germany. (Die Technik des Absatzes deutscher und englischer Steinkohlen in Deutschland.) Hans Jeschke, Z. Handelswiss, 1912, Jan., pp. 333-9.

The Prussian State and the Coal Syndicate. (Der Preussische Staat und das Kohlensyndikat.) L. Eschwege, Bodenref. 1912, 2, pp. 28-30.

II—GEOLOGY

Studies in Mine Surveying. (Studien zur Markscheidekunde.) E. Dolezal, Berg-Huettenmaen. JB., Vol. 59, 1911, 2, pp. 99-134, 2 fig. (Strict compensation of an open polygon.)

The Geology of Coal. J. Sim, Iron Coal Trades Rev., Vol. 84, 2297, pp. 365-6. (The term includes a large number of substances from peat to anthracite, the humic rather than the anthracite are, from the commercial point of view, the most perfect types of fuel. Paper read before the Scot. Fed. Inst. Min. Students, Glasgow.)

The Weathering of Coal Seams. T. Coventry, Mines Minerals, Vol. 32, 1911, 5, pp. 273-5, 2 fig., 3 tab., 1 map. (Peculiar geological conditions at the Charlie Coal Mines, Queensland.)

Metamorphism and Geological Structure in the Narragansett Basin, Rhode Island. F. H. Lahee, Am. Jl. Sci., Vol. 33, 195, pp. 249-62, 7 fig. (The basin is a body of carboniferous strata 50 miles long and from 14 to 25 miles wide, with a stratigraphic thickness of two miles.)

III—MINING TECHNOLOGY

Penn Mary Coal Mines, Heilwood, Penn. R. D. Hall, Coal Age, Vol. 1, 1911, 8, pp. 237-41, 5 fig., 1 map. (Some important and distinctive features of the plant described.)

Ore and Coal Mining Machinery. C. A. Tupper, Mines Minerals, Vol. 32, 8, pp. 454-5. (Their similarity and what each branch of the industry owes the other for its development.)

Buckner No. 2 Mine United Coal Co. Mines Minerals, Vol. 32, 1911, 5, p. 272, 1 fig. (The mechanical equipment of a thick coal bed mine in Illinois.)

An Outline of Mining. W. H. Coghill, Col. Sch. Min Mag., Vol. 2, 1911, 3, pp. 66-7. (An exhaustive outline of all appliances and methods used in every description of mining.)

Coal Cutting Machinery. W. B. Shaw, Colliery Guard., Vol. 103, 2672, pp. 527-9, 12 fig.; 2673, pp. 584-5. (A comparative review of the relative advantages of the various types of rotary machines.)

Crushing Coal for Boiler Use. Mines Minerals, Vol. 32, 1912, 6, p. 349, 2 fig. (The Jeffrey single-roll crusher employed at Pocahontas Consolidated Collieries, McDowell County, W. Va.; this machine has wooden pins on hub engaging holes in pulley; any undue strain shears the pins and stops machine.)

An Anthracite Plant at Hazleton, Penn. Coal Age, Vol. 1, 1911, 10, pp. 310-1, 1 diag. (The Andenried breaker of the Lehigh & Wilkes-Barre Coal Co., handling 1500 tons daily, layout of rolls, conveyors, screens, etc.)

A 150-ton Revolving Steam Shovel for Stripping Operations. Eng. Contract., Vol. 36, 1911, 25, pp. 650-1, 1 fig. (A new type designed for stripping overburden from the coal in Illinois coal fields.)

IV—WORKING OF MINERALS

Elementary Coal Mining. G. L. Kerr, 3rd Edtn., 8vo., 7½x4¾ in., 234 pp., C. Griffin, London, 90c.

A Modern Twin Coal Mining Plant. W. R. Roberts, Coal Age, Vol. 1, 1911, 8, pp. 324-7, 7 fig. (The Bunsen Coal Co., Danville, Ill. The plant runs the two mines in which only the shafts and tipples have individual service.)

Coal Mining Methods in Michigan. R. B. Hosken, Coal Age, Vol. 1, 1911, 8, pp. 242-8, 4 fig. (Interesting use of machines in low levels, in seams 26 to 42 in. thick.)

Methods of Mining in Southern West Virginia. L. J. Marshall, Coal Age, Vol. 1, 1911, 10, pp. 302-6, 5 fig., 1 tab. (The retreating system in gas seam No. 2 Page, Fayette County, W. Va.)

Anthracite and Bituminous Mining. E. T. Conner, Coal Age, Vol. 1, 1911, 9, pp. 277-80, 10 fig. (Methods of operating in New River field, W. Va.; several plants described.)

The Working of the Thick Coal Seams of Upper Silesia. B. C. Gullachsen, Trans. Inst. Min. Eng., Vol. 46, 1912, 2, pp. 209-18, 2 tab., 1 pl.

Maltby Main Colliery. Iron Coal Trades Rev., Vol. 84, 2298, pp. 403-4, 4 fig. (The mines near Doncaster comprise some 6000 acres. The article covers all the operations from sinking the shaft to the delivery of the coal and the mechanical equipment.)

V—BORING, SHAFT SINKING AND TUNNELING

Driving Stone Drifts through Water Bearing Strata. R. Watkin, Iron Coal Trades Rev., Vol. 84, 2294, pp. 248-9. (Some interesting difficulties met with are stated in the paper read before the Yorks. Nat. Assoc. Col. Mgrs.)

Shafts for American Coal Mines. R. G. Johnson, Mines Minerals, Vol. 32, 1912, 6, pp. 344-7, 8 fig. (Methods employed in sinking, their dimensions, timbering or lining with concrete, etc.)

Use of Grout in Shaft Sinking. R. G. Johnson, Coal Age, Vol. 1, 20, pp. 639-41, 5 fig. (One of the chief difficulties of shaft sinking lies in dealing with water encountered. Forcing cement grout into the fissures of water bearing strata by means of compressed air is a new and effectual solution of this problem.)

The Advantages of Freezing as a Method of Sinking Through Heavily Watered or Difficult Ground. W. B. Wilson, N. England Inst. Min. Mech. Eng., Vol. 62, 1911, 1, pp. 36-44. (Some fresh details given in the continued discussion.)

Rules of International Union of Deep Boring Engineers in Vienna. (Satuten des Internationalen Vereins der Bohringenieure und Bohrtechniker in Wien.) Z. Int. Ver. Bohringenieure, 1912, 1, pp. 1-3.

VI—BLASTING, EXPLOSIVES

A New Explosive "Stygia." (Explosivos Stygia.) Mem. Est. Major, Chile, 1912, Jan., pp. 19-20. (This new explosive, invented in Brazil, has all the advantages of dynamite without many of its disadvantages. Description and results of experiments.)

VII—TIMBERING, PACKING, ETC.

Mining without Timber. R. B. Brinsmade, 8vo., Ldn. Hill, 1911, $3.15.

Longwall Mining in Illinois. Mines Minerals, Vol. 32, 8, pp. 451-4, 1 fig., 6 ill., 1 tab. (Plan used in mines of Spring Valley Coal Co. Method of timbering. Building Cogs.)

Accidents in Mines Caused by Falls of Grounds. G. B. Harrison, Trans. Inst. Min. Eng., Vol. 46, 1912, 2, pp. 260-73, 3 tab. (The widespread occurrence of such accidents and the great total mortality from them. Presidential address and discussion.)

Hydraulic Packing in the North of France. Colliery Guard., Vol. 103, 2673, p. 595. (The material used in the Liévin coal mine is the earth removed from the shafts, graded into two grades from 0 to 40 mm. and 40 mm. to 120 mm. in size, and treated in breakers turning out 30 cu.m. per hr.; from the hopper the material is conveyed in pipes to the place of deposit.)

Shaft Raising in Hard Rock. Mines Minerals, Vol. 32, 8, pp. 495-6, 9 fig. (Methods of timbering, drilling, blasting, and handling the rock in shaft.)

The Action and Control of Differently Constituted Coal Roofs. H. Hepplewhite, Trans. Inst. Min. Eng., Vol. 46, 1912, 2, pp. 366-81, 23 fig., 1 pl. (Various methods of supporting roofs described and discussed.)

VIII—WINDING AND HAULAGE

Trials with Electric and Steam Winding Engines. Colliery Guard., Vol. 103, 2670, pp. 426-7, 4 tab. (Report of Committee to German Assoc., Dortmund Min. Assoc. and Boiler Insp. Assoc.)

Mine Headgears. G. Morris, Jl. S. Afr. Inst. Eng., Vol. 10, 1911, 4, pp. 83-5.

Gravity Planes with Monitors. Coal Age, Vol. 1, 1911, 10, pp. 312-13, 6 fig. (The economy in actual practice of gravity haulage, using monitors; available on all grades over 5 per cent.)

Track Arrangement for Shaft Bottoms. O. Cartlidge, Mines Minerals, Vol. 32, 1912, 6, pp. 336-7, 4 fig.

Model Steel Tipple at Annabelle Mines. W. A. Weldin, Mines Minerals, Vol. 32, 1912, 6, pp. 325-31, 12 fig. (Newest methods in building construction and coal handling in West Virginia.)

A Self Dumping Car Haul System. Coal Age, Vol. 1, 19, pp. 605-7, 5 fig. (A description of the Greene car-haul and automatic dumping system as installed at the Burnside Colliery, Penn. The apparatus includes a novel arrangement for recording the work of the tipple and is an important labor saver.)

Haulage System at Gray Creek Mine. F. W. Whiteside, Mines Minerals, Vol. 32, 1911, 5, pp. 264-5, 5 fig.

Wire Ropes as Applied to Mining. D. Baird, Trans. Inst. Min. Eng., Vol. 42, 1912, 1, pp. 129-41, 3 tab.; 2, pp. 288-300. (The increasing danger incurred in the increasing depth of shafts and heavier loads.)

The Shaw Hemsworth Overwinder. T. Beach, Trans. Inst. Min. Eng., Vol. 42, 1912, 1, pp. 92-8, 9 fig. (The effective automatic prevention of overwinding by this device described.)

A Comparison of Electric and Compressed Air Hoisting from Deep Mine Shafts. K. A. Pauly, Eng. Contract., pp. 7-11, 2 fig., 4 tab.

IX—SIGNALING

Relay Indicator Signaling in Mines. J. Charlton, Iron Coal Trades Rev., Vol. 84, 2295, pp. 300-1, 2 fig. (If traffic delays are to be avoided, the system of signaling must be reliable. The speed-

ing up of haulages and the highly organized system of working sets of tubs, increases the value of signaling.)

Luminous Electric Mine Shaft Signaling. J. C. Eadie, Trans. Inst. Min. Eng., Vol. 42, 1912, 1, pp. 37-46, 4 fig. (Paper read and illustrated with working models for both light and sound.)

X—LIGHTING

Ignition of Gas by Electric Lamps. Coal Age, Vol. 1, 15, pp. 478-80. (Belgian tests showing that under certain conditions all electric-lamp filaments ignite firedamp in coal mines.)

The Holmes-Ralph Gas-Detecting Portable Electric Lamp. G. J. Ralph, Trans. Inst. Min. Eng., Vol. 42, 1912, 1, pp. 201-8, 5 fig.; 2, pp. 435-40. (A small lamp described, using only about half a watt and operating detectively by the catalytic action of platinum. Paper and discussion.)

Acetylene in Underground Mining. J. Deszennyi, Acetylene, Vol. 9, 100, pp. 13-4. (Lamps free from soot give bright light on less consumption of oxygen than oil lamps.)

XI—VENTILATION

Effects of Reversing a Main Air Current. J. S. Haldane and J. Bain, Trans. Inst. Min. Eng., Vol. 42, 1912, 1, pp. 155-61. (Discussion with special reference to proposed legislation on mine ventilation.)

Coal Mine Ventilating Equipment. W. M. Weigel, Coal Age, Vol. 1, 14, pp. 441-2; 15, pp. 470-1, 4 fig. (Methods of ventilation by means of mechanical ventilators.) Vol. 1, 19, pp. 610-13, 6 fig.; 21, pp. 671-4, 5 fig.; 24, pp. 769-72, 4 fig. (Description and theory of centrifugal and disc fans.)

The Working of Mines. Lessons on Dynamic Ventilators (Cours d'exploitation des mines.) Leçons sur les ventilateurs dynamiques.) L. Denoël, 4to., 74 pp., ill., Liège, D. et E. Close, 1911.

XII—MINE GASES, TESTING

The Physical and Chemical Properties of Mine Gases. G. H. Winstanley, Min. Eng., Vol. 16, 213, pp. 8-9. (Some criticism of the conflicting standards for inflammable gases and the practical difficulties arising from several of them.)

Release of Gas Accumulations. W. H. Cunningham and C. R. Conner, Coal Age, Vol. 1, 1911, 12, pp. 370-1, 1 fig., 1 map. (Borings release gas from abandoned mines.)

Methods of Testing for Mine Gases. W. R. Crane, Coal Age, Vol. 1, 1911, 12, pp. 376-7. (Additional tests given in paper read before Coal Min. Inst. Am.)

The Composition of Some Mine Gases. G. A. Burrell, Chem. Eng., Vol. 15, 1, pp. 1-8, 8 tab. (Also gives a description of a Simple Methane Apparatus. Read before Coal Min. Inst. Am.)

Pathogenic Mine Atmospheres. E. W. Chance, Coal Age, Vol. 1, 14, pp. 448-50, 6 tab. (The cause and conditions governing flame extinction and death by smothering gases in mines.)

XIII—COAL DUST

Automatic Sprinkling Apparatus for the Prevention of Dust in Mines. T. C. Futers, Coll. Guard., Vol. 103, 2662, p. 24, 3 fig.

The Use of Stone Dust in Relation to Coal Dust Ignition. W. C. Blackett, Iron Coal Trades Rev., Vol. 84, 2297, pp. 368-9. (Some simple applications for the prevention of explosions of coal dust being carried along the pit roads, are given in a paper read before the N. Eng. Nat. Assoc. Coal Mgrs.)

The Influence of the Presence of Gas on the Ignition of Clouds of Coal Dust by Single Electric Flashes. W. M. Thornton, Iron Coal Trades Rev., Vol. 82, 2294, p. 253, 2 fig., 1 tab. (Some new experiments described, and the results compared with former experience. Read before N. Eng. Assoc. Min. Eng.)

British Coal-Dust Experiments. W. E. Garforth, Trans. Inst. Min. Eng., Vol. 46, 1912, 2, pp. 220-45. (A full report of Altofts experiments are presented and lessons deduced from the investigation.)

Experiments on Liquid Mixtures for Laying Coal Dust. W. M. Thornton, Trans. Inst. Min. Eng., Vol. 42, 1912, 1, pp. 66-86, 1 tab.; 2, pp. 417-24. (The use of liquid soaps, disinfectants, water glass, solvents, binders, cresol, caustic soda and other mixtures dealt with and discussed.)

XIV—EXPLOSIONS

The Prevention of Explosions. Dr. J. Harger, Coll. Guard., Vol. 103, pp. 2671-3. (Discussion of the author's views on the possibility of preventing coal-dust explosions as presented before the Man. Geo. Min. Soc.)

The Briceville Mine Explosion. R. D. Hall, Coal Age, Vol. 1, 1911, 11, pp. 343-7, 4 fig., 1 map. (Much dry coal dust present through spilt coal in haulage, fan at foot of shaft, the Cross Mountain Mine, Knoxville, Tenn.)

Botton Creek Mine Explosion. Mines Minerals, Vol. 32, 1912, 6, pp. 332-3, 2 fig. (Conditions in the mine at the time of the explosion, its effect minimized by the moisture, quantity and split up supply of air. The steam-jet system.)

XV—MINE FIRES

Notes on Underground Fires. J. Ashworth, Coal Age, Vol. 1, 21, pp. 668-70. (Instances of fires caused by criminal negligence, carelessness, and the disregard of rules and mine regulations. Lessons taught by mine disasters. Spontaneous combustion in mines. Effect of mine temperatures. Direction of air current from pyrites in coal. Manner of handling mine fires.)

Extinguishing the Majestic Mine Fire. R. Y. Williams. Mines Minerals, Vol. 32, 1912, 6, pp. 342-3, 1 map, 1 tab. (Investigation by men wearing oxygen helmets enabled effective action to be taken.)

Earthquakes and Mine Explosions. Coal Age, Vol. 1, 22, pp. 702-3. (Discussions at the Conference of the International Association of Seismology on Radio-Active Products as Source of the Earth's Heat. Formation of mountains and valleys. The earthquake and the pendulum. Correspondence of seismic unrest with mine explosions.)

XVI—RESCUE AND AMBULANCE

Mine Rescue Work in Illinois. H. H. Stoek, Coal Age, Vol. 1, 19, pp. 598-600, 6 fig. (The rescue stations and three rescue cars. Men from these cars attend all mine disasters and train mine-rescue men at the surrounding mines.)

Use of Oxygen Helmet in High Temperatures. H. H. Sanderson, Mines Minerals, Vol. 32, 1912, 6, p. 335. (Tests carried out at Virginia City, Nev., at the 2450-ft. level in 165 deg. of temperature give satisfactory results.)

XVII—DRAINAGE, PUMPING, ETC.

The Evolution and Present Development of the Turbine Pump. E. Hopkinson and E. L. Allan, Machinery, Vol. 18, 7, pp. 533-6, 9 fig. (The evolution of the Osborne-Reynolds pump is traced, as being typical of the turbine pump at large.)

XVIII—PREPARATION

Consolidated Coal Washery at Saginaw, Mich. Mines Minerals, Vol. 32, 8, pp. 468-9, 4 ill.

Standardization in Coal Washing. G. R. Delamater, Mines Minerals, Vol. 32, pp. 461-5, 2 tab. (A plea for uniformity in tests and reports. Formulas for accurate comparison of washery work.)

Washing and Sorting of Small Coal. N. T. Williams, Cassier's Mag., Vol. 40, 1911, 7, pp. 606-28, 13 fig. (The apparatus employed in cleansing coal.)

XIX—BRIQUETTES

Automatic Furnaces for Brown-Coal Briquettes. (Maschinelle Fuerungen fuer Braunkohlen briketts.) El. Anz., 1911, 98, pp. 1263-64; 101, pp. 1301-3, 12 fig., 3 ill. (Automatic feeding device.)

Briquetting Presses Driven by Three-Phase Commutator Motors. (Brikettpresses-Antrieb mit Drehstrom-Kollekttormotoren.) Druckschr. Siebens-Schuckertw. (Working results, description of plants.)

Electric Driving of Briquetting-Presses. (Der elektrische Antrieb von Braunkohlenbrikettpressen.) A. Strauss, Techn. Rdsch., 1912, 7, pp. 74-5, 2 fig., 2 ill. (Description of two plants built by the Siemens-Schuckert Works.)

XX—COKE OVENS

Treating Coal for Coke Making. Coal Merchant, Vol. 24, 589, pp. 11-12, 4 fig. (The great advantage of washing, mixing, and crushing before charging the ovens.)

Source of the Coking Property of Coals. H. W. Hempel and F. Lierg, Jl. Gas Light., Vol. 116, 1911, 2536, p. 822. (From Zeit. für angewandte Chemie.)

Continuous Coking in Vertical Retorts. Coal Age, Vol. 1, 1911, 10, pp. 314-6, 2 fig. (Description of retorts, their numerous advantages and maximum efficiency.)

Development of a Byproduct Coke Oven Gas Plant. W. S. Blauvelt, Am. Gas. Jl., Vol. 96, 11, pp. 169-71, 4 fig., 1 tab. (In thermal efficiency and in total yield of gas the byproduct oven compares favorably with the best gas benches. All difficulties in the operation of the byproduct oven gas plant have been overcome.)

A Horizontal Flued Coke Oven. J. R. Marsden, Iron Coal Trades Rev., Vol. 84, 2298, p. 405, 3 fig. (Deals with several points of comparison between the horizontal and vertical flued ovens; and states that for simplicity and comfort in working, cost of upkeep and repairs, the horizontal is distinctly the better.)

A Retort Coal Quencher and Loader. A. Goodall, Coal Age, Vol. 1, 21, pp. 678-9, 3 fig. (Describes an apparatus for quenching and loading coke from retort ovens in one operation. A number of plants are in successful operation in England, and it is claimed that the machine will effect a considerable economy of labor.)

Modern Coking Plants with Utilization of the Byproducts. (Moderne Kokereien mit Gewinnung der Nebenprodukte.) A. Wagner, Bergbau, 1912, 1, pp. 1-6; 2, pp. 13-8; 3, pp. 29-33; 4, pp. 45-9, 23 fig. (Preparation of the coal; coking ovens; utilization of the byproducts.)

XXI—FUEL TESTING

Gas and Fuel Analysis for Engineers. A compendium for those interested in the economical application of fuel; prepared especially for the use of students at the Massachusetts Institute of Technology. A. H. Gill, 6th Edtn., 12mo., 7+139 pp., ill. N. Y., Wiley, 1912, $1.25.

The Testing of Coal. C. Ostler, Jl. Gas. Light., Vol. 117, 2546, pp. 582-4. (The paper shows what testing can be done in a small test plant.)

Coal Dust as Fuel. H. V. Hart-Davis, Iron Coal Trades Rev., Vol. 84, 2295, pp. 298-9, 3 fig. (A coal-dust fuel boiler and its uses are described. Much dust is allowed to blow to waste at the pit mouth which is of high calorific value.)

Deterioration of Coal in Storage. H. C. Porter and F. K. Ovitz, Mines Minerals, Vol. 32, pp. 475-6. (Results of experiments showing effect of weather on various coals under different conditions.)

XXII—STEAM ENGINES AND BOILERS

Steam Regenerative Accumulators. D. B. Morison, Coll. Guard., Vol. 103, 2674, pp. 629-32, 10 fig. (The Fife Coal Co.'s collieries illustrate the amount of mechanical power required to operate the plant necessary for coal getting at a group of modern pits. Four stations are each equipped with mixed pressure turbo-generating units of 750 kw. capacity. Exhaust steam is utilized to an exceptional extent.)

Methods of Driving by Gas Engines for Collieries. A. E. L. Chorlton, Trans. Inst. Min. Eng., Vol. 46, 1912, 2, pp. 315-50, 25 fig., 3 pl., 2 tab. (Some methods of drive, possibly as economical, if not more so, than the customary electrical modes.)

Bettington Boilers for Pulverised Fuel. Ry. News, Vol. 96, 1911, 2503, pp. 1422-3, 3 fig. (Efficient combustion promoted by intimate mixture of air and fuel.)

Power Installations in Pits; Gas, Steam and Electricity. (Installations motrices des houillières; le gaz, la vapeur et l'électricité.) J. Burns, Lumière El., 33, 1911, Vol. 26, 46, pp. 208-11.

XXIII—ELECTRICITY

Colliery Cables. H. G. Fraser, Iron Coal Trades Rev., Vol. 84, 2294, pp. 254-6. (A discussion upon the installation and maintenance of high-tension vulcanized bitumen cables. If the current density is kept within the limits laid down by the Home Office it may be used up to, or even above, 6600 volts.)

Electrical Accidents in Mines. M. Pickering, El. Rev. (Ldn.), Vol. 69, 1769, pp. 678-80. (Wire armoring and wooden casing as preventive of trouble in cases of roof or side falls or iron girders or runaway tubs.)

Winding Plant with Electric Drive by Variable-Speed Three-Phase Motors. El. Eng., Vol. 8, 5, Supp., pp. 9-11, 4 fig. (Plant of the Deri Motor for shaft depth 690 ft., net load 1.6 tons, speed 20 ft. per sec.)

Electric Transmission in Coal Mines. H. D. Jackson, Coal Age, Vol. 1, 15, pp. 484-5. (The true cost of electric power, rail, bonding, calculation of copper required.)

Electrical Equipment of the D., L. & W. Mines, Penn. Coal Age, Vol. 1, 23, pp. 742-4, 4 fig. (An unusually complete and extensive electrification, motor capacity 27,618 hp. The central station and substation practice is outlined and the electric power in haulage, hoists, pumps and auxiliaries.)

Electric Winding Developments. F. Thursfield, Trans. Inst. Min. Eng., Vol. 42, 1912, 1, pp. 179-90, 1 fig. (Discusses the use of electric drive where waste gases or exhaust steam are available, but deprecates the substitution for live steam.)

Home Office Rules for the Installation and Use of Electricity in Mines. Iron Coal Trades Rev., Vol. 84, 2295, pp. 279-80. (Showing the alterations from the original draft which are of considerable importance.)

Motor Starters for Mining Work. A. P. Drake, Iron Coal Trades Rev., Vol. 84, 2295, pp. 287-8, 23 fig. (Resistance units, resistance starters, and alternating-current motor starters are all dealt with.)

XXIV—SURFACE TRANSPORTATION

Coal Developments at Stearns, Ky. J. E. Butler, Mines Minerals, Vol. 32, 8, pp. 481-2, 3 ill. (Use of an aërial tramway to transport coal across a river. Description of equipment and surface arrangements.)

Anti-breakage Coal Shipping Apparatus. Coal Merchant, Vol. 24, 591, pp. 55-6, 4 fig. (Particulars of the Handrock appliance with endless chains carrying steel plate trays, upon which the coal travels.)

The Largest Naval Collier in the World. K. G. Martin, Marine Engineering (N. Y.), Vol. 16, 12, pp. 495-8, 3 ill. (Characteristics of U. S. A. fleet collier "Cyclops." Description of deck arrangement and coal-handling machinery.)

XXV—SANITATION, DISEASES

Colliery Cottages and Surface Buildings. J. Perkin, Iron Coal Trades Rev., Vol. 83, 1911, 2286, pp. 1022-3, 9 fig.

Model Concrete Village for Coal Miners. Concrete, Vol. 12, 2, pp. 40 and 66-7, 13 fig. (A village of 20 double houses for 40 families, arranged around a park 300x600 ft. They are built so that the house cleaning can be mainly done with the garden hose. Many interesting devices are given.)

Coal Mine Mortality Statistics. F. L. Hoffman, Coal Age, Vol. 1, 13, pp. 400-3, 4 tab. (Tables showing the rapid increase in the death rate in North American mines.)

Miners' Baths. R. A. S. Redmayne. Coll. Guard., Vol. 103, 2663, pp. 77-8, 6 fig. (Bath installations described as at Dolwath, Cornwall, and in Belgium and France.)

Watch Out For The Sulphurettes!

They'll get you if you don't. For there are millions of the little imps picking and pecking away, day and night, in your mine, in every coal mine—working quick death and destruction to pipes left unprotected against their ravages.

If you've never thought of it, just stop a minute and figure up what the Sulphurettes cost you last year—in new pipes to replace those eaten up by sulphur-permeated mine water, in tearing up the old and laying the new, in interruptions to your work.

Then cut that cost in half and you'll get the *bottom* figure you will save by painting your pipes with **Highland Non-Corrosive Coating.**

Others are doing it right along—everywhere. Want the proof? Just ask us for it.

Want the *best* proof? Send for free six-months trial quantity. It's easily applied; it dries quickly; it won't chip off; it's sure protection.

So send for a free-trial lot!

COAL AGE

Devoted to Coal Mining and Coke Manufacture

Volume 1, No. 31.
Issued Every Saturday.
Hill Publishing Company.

NEW YORK, MAY 11, 1912

Ten Cents per Copy.
U. S. and Mexico, $3 per Year.
Canada, $4; Other Countries, $5.

Why Is Over $616,000,000 A Year Spent In Advertising?

Because manufacturers want to support publishers and advertising men? Or because it pays the manufacturer and the publisher?

Not on your life!

The only reason on earth for that expenditure is because advertising pays the *reader* of the ads who *buys* the advertised goods.

Then, and only then, it pays the advertiser—and after him the publisher.

You readers are the ones who can profit most by advertising. It gives you a ten times better paper than we could afford to give you without it.

It tells you the latest news and information about the machinery, equipment and supplies for your mines.

It offers you a complete catalog, bulletins and other data on any product you need.

It is clearly, plainly written and well illustrated.

It is the modern salesman that will tell you all you want to know about the things you have to use.

The advertising section of your technical paper is a collection of invaluable up-to-date information that you can't buy anywhere else at any price.

Are you taking full advantage of it?

Are you reading the "Selling Section" of Coal Age each week?

Remember, advertising has become a tremendous power only because it pays you to read it and to buy the goods advertised.

CA

COAL AGE

Vol. 1 NEW YORK, MAY 11, 1912 No. 31

THE eyes of the world have been watching the various phases of state activity in New Zealand, hoping to learn something that might be used in the social reform of other nations. Having become the sociological experiment station of the universe, she is rather expected to try out all radical ideas for the benefit of humanity. The country is remote, has a homogeneous population of intelligent, well educated people who have a high standard of public virtue; the climate is healthful and the soil fertile, so that important conditions are favorable to the work in hand.

If in any country, therefore, the ideals of Utopia could be realized, surely New Zealand affords the chance. But has the aim been accomplished? Let us briefly analyze the results the government has secured from having established Old Age Pensions, Parcels Post, Savings Bank, Fire Insurance, Life Insurance, a system of Telegraphs, Telephone Exchanges, and from operating Coal Mines.

To receive a state pension the citizen must be 65 years old, sober and reputable and 25 years a resident. His income must not exceed $300 annually, and his accumulated property must not amount to $1300 or over. The full pension of $130 a year is reducible by $5 for every $5 of income over $170. Thus when the applicant's yearly income reaches $300, the right to any pension is lost. Likewise, a reduction of $5 is made for every $50 of accumulated property.

As to state insurance, state ownership of mines, and government management of railways and other public enterprises, the plan of conducting all such activities on sound business principles has lately been adopted. This policy prevails not only where the state is competing with private effort, but in government monopolies, where lack of competition tends to cause expensive management, obsolete methods and unreasonable concessions to public clamor. The present aim is to make each business pay at least interest on the capital invested.

The most recent reports at hand show that the annual profits of the Post and Postal Telegraph Departments are approximately $500,000. The State Coal Mines netted the government another $100,000. The railways showed a deficit of $1,030,000, while the net profits to the state from 5 per cent. loans made to settlers was $325,000.

Telegrams and telephone service are cheaper than in the United States. Railway fares are practically the same (2c. per mile). The price of coal is higher than when the government first went into the business. Wages, as compared with the cost of living, are slightly lower than in this country, and the net public debt of New Zealand ($329,000,000) amounts to $340 per head, which forms a striking comparison with our net debt of $10 per head. The enormous net debt of New Zealand, however, does not seem so great when compared with the total private wealth of the country, which is $1628 per head, a greater per-capita wealth than that of any other nation.

It would be unfair to say that the mild form of socialism prevailing in New Zealand is a failure. But has it improved conditions? Of 1,000,000 inhabitants, 130,000 are directly dependent on the state. Poverty has not been abolished, for there are just as many paupers in the towns of New Zealand as in American cities. Also the distribution of wealth is not much more equal, since statistics show that 1 per cent of the families in that country own 35 per cent. of the wealth, a condition but little better than that which exists in the United States.

Strange to say, socialistic legislation has had an effect that certainly was not socialistic. Discontented and land-hungry laborers, through state aid, have been converted into prosperous citizens, strong supporters of the freehold and ardent advocates of the sanctity of private property.

There is still a discontented class, who, having little to tax and nothing to lose, desire to exploit the rich, regarding the capitalist as a goose to be kept for the sake of its golden eggs. We should study New Zealand's scheme of compulsory arbitration and her system of old-age pensions. Also, if it will make our coal industry more stable, we would like to see Uncle Sam operating a few mines of his own, but to believe that results so far attained in this far-off country point a way out of the tangled woods of social unrest is hardly justified by the facts that exist.

The Acme Co.'s Plant in Wyoming

By Jesse Simmons*

A detailed description of one of the largest and best equipped plants in the Sheridan, Wyo., field, a general description of which was recently published in COAL AGE. An unusual refinement in sizing the coal is attained by the use of a shaking screen with both a lateral and longitudinal motion; this is one of only four or five such screens in use in this country.

*Deadwood, S. D.

The mines of the Sheridan, Wyo. coal field are operating on seams that have been designated by the Geological Survey as sub-bituminous, but are more commonly known locally as lignite. Whether this coal is a true lignite, in the common acceptance of the term, is a question the Survey men evaded by giving the new name. The coal differs from the ordinary lignite in that it contains less moisture and far less ash. In color it is black instead of brown, and it has a high gloss, almost as bright as the best grades of anthracite. It burns freely to a clean, light ash, having a resemblance to wood ash.

Because of the fact that it is mined from large clean seams and nearly all of the mines leave a coal roof, the resulting product is exceptionally clean. It contains barely more than traces of sulphur. For steam purposes it is a good fuel, and is used in large quantities by the C. B. & Q. R.R. As a coal for domestic use it is in some ways superior to the ordinary bituminous, as in burning it leaves almost no soot, and for this reason, as well as its freedom from clinkers and sulphurous gas, it derives merited popularity.

Of the several mines in the Sheridan district the newest and one of the best equipped, as well as one of the largest, is the Acme Coal Co.'s property. This company is but two years old, and owns three mines. Mine No. 3 is operating in the top seam of the district, which is known locally as the Monarch. Mines 1 and 2 are working in the Carney, or second seam, the Monarch being eroded at this point. Mines 1 and 2 are on a property comprising about 300 acres, 3 miles west of the 1100-acre tract on which Mine No. 3 is located. The former property is operated under a short term lease, and the latter under a ninety-nine-year contract. All three openings are made in the bluffs of the Tongue River, by drifts having a slight inward dip.

The Acme No. 3 Mine

The main entry of the Acme No. 3 mine is in the bluffs of the Tongue River, on the northerly side of the stream. From the pit mouth the track, which has a 42-in. gage, and is laid with 45-lb. rails, both on the surface and in the main haulageway, follows the bluffs westerly, and crossing a steel bridge, enters the yards. At a point 250 ft. from the foot of the inclined approach to the tipple, the electric locomotives are uncoupled and the cars picked up, one at a time by a cable haul. The essential features of this haul are a 1¼-in. steel cable to which are attached 4-wheel trolleys, equipped with dogs which engage lugs on the car axles, the trolleys running on 16-lb. rails. The haulage is controlled by a friction clutch, making it possible to give the proper feed to the cars going up the incline.

Acme Co.'s Steel Tipple, Showing Re-screening Plant and Chutes

At the foot of the incline the cars are picked up by a cable haul similar in detail to the one described, which takes them to the top of the tipple. The top of the incline is 49 ft. above the yard tracks, and has a grade of 15 deg. The cars are dumped over a crossover dump, and automatically transferred by means of a double track system, down the approach, and made up into trains for return to the mine.

When the coal is dumped from the mine cars it enters a large bin provided with a movable bottom, or feeder plate, arranged to be operated at varying rates of speed. This delivers the coal to a shaker-screen of special design having a capacity of 3000 tons per day and openings 6 in. in diameter. Having both longitudinal and lateral motion, the makers of this screen claim it has an important advantage over other types. It is one of four or five in this country, but it has been extensively and successfully used in Germany.

From this screen coal may be diverted into either open or box-cars, a standard Ottumwa box-car loader being used to load the latter. By cutting out the screen, which is done by covering it with movable steel plates, mine-run may be loaded direct into the cars. As a further precaution in the preparation of lump, the coal before entering the railway cars passes over grizzlies, thus removing the last vestige of slack and dust which might have been carried to this point.

Re-Screening Plant

The coal passing through the shaker-screen may be either diverted to open cars on the slack track, or to an elevator boot from whence it is conveyed by a 30-in. rubber-belt conveyor, 265 ft. long, to a revolving screen 65 ft. above the ground, at the top of what is known as the re-screening plant. This screen is 24 ft. in length, and for one-half of the length an outer screen, 7 ft. in diameter surrounds the main screen, which is 6 ft. in diameter. Beginning at the upper end, the openings in the main, or 6-ft. screen, are as follows: 1-in., for the first 12 ft.; next a 6-ft. section with 2-in. openings, while the remaining 6 ft. has 3½-in. openings. The outer screen has ½-in. openings, and surrounds that portion of the inner screen having 1-in. openings.

The following grades of coal can be made at this plant: At the main tipple, lump, mine-run and slack; at the re-screening plant, slack, pea, nut and egg. The slack is that portion passing through the ½-in. opening; the pea size drops

through the 2-in. opening; the nut through the 3½-in. screen, and the egg is that product which has passed through the 6-in. screen in the tipple and over the 3½-in. The regular grades may be dumped into their respective bins at the re-screening plant, or the product may be mixed if desired, making not only the four sizes of coal as originally prepared, but a combination of these sizes to meet special market conditions.

The bins into which the coal is screened are made entirely of steel, and are of latest modern construction. In order to prevent any breakage of the coal after having been prepared in the revolving screen, it is conveyed to the bottom, or coal level, in the bin by means of special chutes, constructed as follows: The chute proper is a steel box, standing nearly vertical and provided with a series of sloping steel shelves. The coal in passing down the chute pursues a zig-zag course from shelf to shelf, and finally arrives at the coal level in the bin without having dropped at any time, a distance which would cause it to break. This scheme is largely followed in the anthracite territory, as being the best method of handling coal with minimum breakage.

Jeffrey Motor at the New Acme Mine

Beneath the storage bins, which have a capacity of 500 tons, are three railway tracks, where coal may be loaded from the bin. The mouths of the loading chutes are provided with grizzlies, similar to the equipment at the tipple, for removing slack. At both this point and the tipple, the slack is picked up by screw conveyors, 6 in. in diameter, and delivered to bucket elevators housed in steel, which returns the material to the screens. This eliminates considerable hand labor and keeps the loading tracks free from accumulations of coal.

At the re-screening plant the bins are provided with hoppered chutes over the center track, for loading open cars. The two tracks at the side are equipped with chutes for loading box-cars only. The hoppers over the center tracks are equipped with improved clam-shell delivery gates. The entire plant is operated by electricity, power being secured from the Sheridan Electric & Power Co., whose plant is close to the tipple, as shown in the illustration. Westinghouse, alternating current, 3-phase, 60-cycle motors, having a capacity of 2300 volts are used for driving the tipple and screening plant, one 60-hp. motor being used at each place. The electric locomotives and coal cutters are driven by 250-volt direct current.

Machine Shop

The machine and blacksmith shop is a reinforced concrete building, 40x60 ft., with a steel roof, and equipped with the machinery for making all necessary repairs to cars, mining machines, etc. A side track runs into the shop and over a pit, giving easy access for a man to work under the cars in making small repairs. A steel tank with a capacity of 75,000 gal. on a steel frame 75 ft. high, supplies the miners' cottages, etc.

Acme Co.'s Tipple and Sheridan Electric Light & Power Co.'s Plant

The tipple, re-screening plant and bridge across the Tongue River are all constructed of steel, resting on heavy concrete pillars. The work was done under contract, by the Ottumwa Box Car Loader Co., of Ottumwa, Iowa. The plant was designed by the manager of the Acme mines, A. K. Craig, of Sheridan, and machinery and equipment has been purchased from a number of manufacturers, it having been his endeavor to secure the best in each particular line.

The Acme No. 3 mine started producing mine-run coal, for railroad use, in February 1911, and during October the new tipple was put in operation. The re-screening plant will go in commission at an early date, and this mine will then be equipped to produce 3000 tons of coal per day—and a coal that will have as good a preparation as any produced in the field.

At this mine Jeffrey mining machines are used exclusively, both breast and longwall types; they are operated by a 250-volt direct current. A Sullivan high speed fan, motor-driven, furnishes the ventilation, the 30-hp. motor on this machine being driven by a 2300-volt, alternating current. Jeffrey electric locomotives are used for haulage. At the present time the camp includes a few temporary shacks, and 20 employes' cottages, completed or under construction; a large building, combining a boarding house, offices, etc., is also being built. As fast as necessary additional dwellings will be erected, and when a store, school, church, etc., are completed the camp will be quite an imposing one. The mine is about one-half mile from the main transcontinental line of the C. B. & Q. R.R., the grade being almost level for this distance.

Method of Mining

In a recent report made by Jno. K. Seifert, the workable coal in the 1100-acre tract of the No. 3 mine, is placed at a thickness of at least 35 ft. This is contained in two seams, the Monarch or upper seam, having 26 ft., 4 in. of workable coal, and the Carney or second seam, about 9 ft. of workable coal. The present openings on this property are made in the Monarch seam, the Carney, which is 42 ft. below, being held in reserve. The workable coal in this track is figured at 38,500,000 tons.

Owing to the thickness of the Monarch seam, the ordinary methods of mining cannot be followed to advantage. There is about 23 ft. of absolutely clean coal in this seam, which can be mined without touching any kind of rock, bone or inferior material. In general it has been found that the room-and-pillar method, driving the rooms 10 to 12 ft. high, and later drawing the pillars, bringing down the roof, gives a high percentage of recovery. The panel system is used, as it is found necessary to stop up abandoned workings, since the disintegrated and dirty coal has a tendency to ignite from spontaneous combustion if left too long exposed to the air.

Manager Craig, of the Acme mines, has devised a system of mining which is about to be patented. He claims for this system a higher recovery of the workable coal in these large seams than

is possible by any of the methods now in use at the various mines. As stated he is about to apply for a patent, having practically completed all of the preliminary work and experimentation.

Mining Conditions

The mines of this district are particularly fortunate in that they have absolute freedom from many of the disadvantages which mark coal operations in other districts. The mines are free from gas, probably due to the fact that the veins are found not far below the surface, while the superimposed strata is largely sandstone or other porous rocks. In mining with a coal roof very little, in fact almost no, trouble is experienced with caves or falls of rock which would injure workmen.

The Acme mine is typical of the district as regards freedom from accidents; during the two years that this mine has been open there has not been a single fatal accident, and no serious accidents of any kind. The freedom from gas makes ventilation a fairly simple problem, in fact the fan equipment at these mines would be totally inadequate were there any gas present. The fans are practically used only for the purpose of blowing out powder smoke.

The one drawback, which is not serious if anticipated and properly guarded against, is danger from fire. The slack coal, especially if mixed with dirt and rock where the roof has come in, in some abandoned room, is very likely to ignite from spontaneous combustion. Knowing this the operators use the panel system of mining, usually running about 30 rooms to a panel. Thus, when a 30-room panel has been worked out, it is only necessary to stop two openings in order to completely close up the section. These stoppings are ordinarily made with concrete.

Analysis of the Coal

The following analyses were made by the Commercial Testing & Engineering Co., Chicago:

Sample top to bottom of 8-ft. seam, Acme No. 1:

Moisture	17.83
Ash	4.11
Volatile matter	58.20
Fixed carbon	19.86
Total	100.00
B.t.u.	9950
Sulphur	0.24

Lower 12 ft. of Monarch seam Acme No. 3:

Moisture	17.92
Ash	3.58
Volatile matter	44.81
Fixed carbon	33.69
Total	100.00
B.t.u.	10,247
Sulphur	0.39

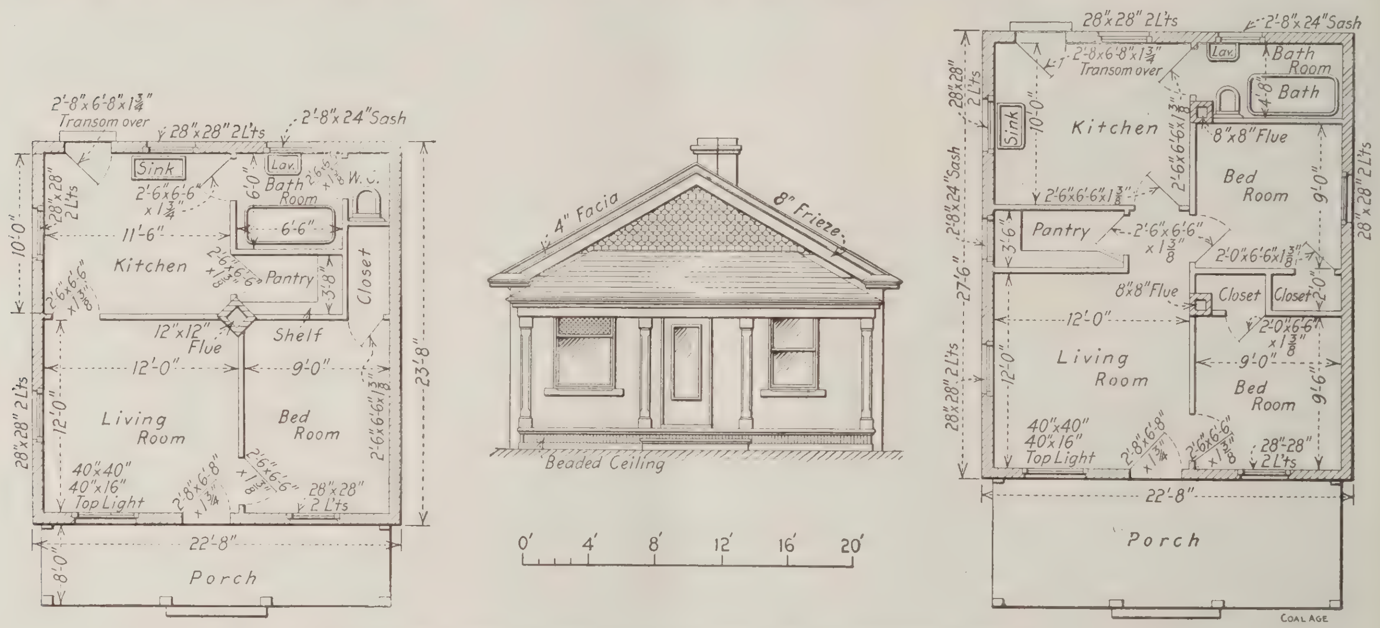
This quality of coal would make a splendid fuel for use in gas producers, probably as good, or better than the high class Virginia bituminous coal. These analyses are typical of this section, and when it is considered that this coal is mined absolutely free from foreign material (both the floor and roof being coal) it at once marks this district as unique in the coal industry.

Acme Nos. 1 and 2

The coal from the Acme Nos. 1 and 2 mines is dumped over a single frame tipple; both mines are drifts, with slight inward dips. The coal is mined from the Carney seam, the thickness varying from 9 to 12 ft. Like the Acme No. 3, the room-and-pillar method, combined with the panel system, is used. Rooms are 16 ft. wide and 200 ft. long, leaving 15-ft. pillars. Four Jeffffrey short-wall machines are used for undercutting. The miners drill and blast their own coal, which work, as well as undercutting and loading, is done on a schedule per ton made with the local Miners' Union. These Unions are affiliated with the United Mine Workers.

Two 5-ton Jeffrey electric locomotives are used in bringing the coal from the main partings to the tipple; horses are used in the rooms. The mines are electrically equipped, power at 22,000 volts, 3-phase, 60-cycle, alternating current being obtained from the Sheridan Electric Light & Power Co. This current is stepped down in three, 75-kv.-a., Westinghouse transformers to 2300 volts, and then drives a motor generator set, composed of a 220-hp., Allis-Chalmers motor, direct connected to an Allis-Chalmers, direct current generator, producing at 1130 r.p.m., a 250-volt, 545 ampere current; this current is used for the undercutting machines, locomotives and tipple. In addition to the above equipment, the transformer house contains a small transformer for stepping the current down to 110 volts for the lighting circuit, used both in the mine and town. As at present operated this plant is capable of producing 1000 tons of coal in 8 hours.

With the three mines mentioned the Acme Coal Co. is a strong competitor for the business of the Sheridan field, and the completion of the plant at No. 3 will place the company in splendid position. The Acme Coal Co. is owned by two men, A. K. Craig and Ora Darnell. The former is the practical miner and the latter the selling head. Both are well qualified for the work they have undertaken, having had long experience in the coal business. To both of them the writer desires to acknowledge the courtesies which have made it possible to secure the data for this article.

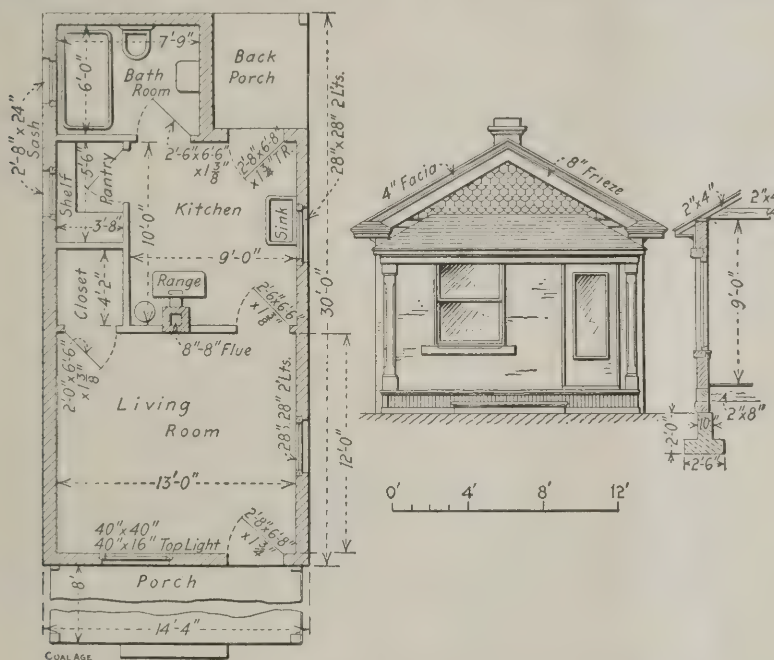


Plan and Front Elevation of Three-and Four-room Houses

Employees' Residences

In keeping with the equipment of the mine, the company is erecting a group of dwellings for the housing of employees which will bear comparison with those of any mining camp in the country. The plan of house No. 3, which is reproduced herewith, is typical of the village which is being buit. House No. 3, as it is designated in the specifications, has four rooms besides a bath room, pantry and two closets; the conveniences include a front porch extending the width of the building, electric lights, running water, sewer connections and hard pine floors. The extreme dimensions of the outside walls give the house a width of 22 ft., 8 in. and a length of 27 ft., 6 in.

The foundation is of concrete, with two courses of concrete blocks laid



Plan, Elevation and Partial Section of Two-room House

above the ground line; upon the foundation, and butting upon the blocks, are laid the floor joists, and upon these the rough floor is spiked and the studding raised. After the studding is raised and the outside weather boarding put on, the inside of the exterior walls is boarded up with rough lumber and into the space thus formed, between the ship lap and sheathing, concrete is poured and well tamped. After the wall thus constructed, and into which pipes carrying the electric wiring have been introduced as the work progresses, the interior rough boarding is removed and the wall pointed up with rich concrete. A coat of alabastine or whitewash completes the interior wall.

Aside from this innovation in construction, the house is completed in the usual workmanlike manner, good plumbing being used, and a heavy coating of paint protecting the woodwork. Partition walls are of the usual construction, 2x4 studding and lath, plastered with two coats and finished hard and smooth. Chimneys rest on concrete piers which extend from the solid ground up to the floor level, taking the weight off the floors. A house of this description rents to an employee for $20. per month, including water, light and coal.

House No. 1 contains two rooms, a living room, 12x13-ft., and a kitchen 9x10-ft., besides a bathroom, pantry and closet. House No. 2 contains three rooms, a living room 12x12-ft., bed room 9x12-ft. and a kitchen 11 ft., 6 in. x12 ft., also a bathroom, pantry and closet.

Power Plant

The Sheridan Electric Light & Power Co. has a most uptodate power plant on land belonging to the Acme Coal Co., having the surface right under a 50-year lease. The location is 9 miles from the city of Sheridan, a place of 10,000 inhabitants, which is served by its pole lines. The coal mines of the Sheridan district are close at hand, the most distant operating mine, the Kooi, being only a little over 3 miles away.

An interurban electric road is building from Sheridan to the coal mines, and has contracted for power generated at this plant. From these details it will be seen that the plant has a convenient location for the generation of power for the city of Sheridan, and is advantageously situated to give service to the mines and electric railway.

The plant is located about 200 ft. from the Acme No. 3 tipple, and it is the intention to install a conveyor for transferring the coal from the tipple to the boiler room of the plant. The boiler room contains three, Heine, water-tube boilers, one of which is being operated under a test with a Roney stoker; should this machine prove successful in the handling of lignite slack, a large field for its use will be opened up. There is demand for a stoker which will fire the slack coal from the Sheridan mines, as dozens of steam plants in Wyoming, South Dakota, Nebraska, etc., are using coal from this field, and a very large proportion of them are using hand firing.

The superheated steam from these boilers is fed to two, Westinghouse-Parsons turbines, direct connected to Westinghouse alternating current generators, which at 3600 r.p.m., produce 1250 kw. of 2300-volt current. Further equipment in the engine room includes transformers which take the 2300-volt current and step it up to 22,000 volts, which is the line pressure. Some of the 2300-volt current is used at the adjoining coal property, and a motor generator set, in the same room, is driven by this current. This set comprises an Allis-Chalmers, 220-hp. motor, actuated by 54 amperes of alternating current, 60-cycle, 3-phase, at 2300 volts, direct connected to an Allis-Chalmers, direct current generator, producing current at 250 volts no load, 275 volts full load, 545 amperes; the set operates at 1130 revolutions per minute.

Exhaust steam from the turbines is taken through a Leblanc condensing system. Water for this system is taken from the Tongue River, on the banks of which the plant is situated.

Annual Banquet of Mine Officials at Pittsburg

Superintendents, mine foremen, assistant foremen and fire bosses of the seventeenth bituminous inspection district of Pennsylvania held their first annual banquet at the Monongahela House, Pittsburg, on Saturday evening, April 13. One hundred and fifty-four mining men of the district were in attendance.

W. H. Pratt was elected toastmaster and with a few appropriate remarks called upon the following, to address the gathering: J. I. Pratt, mine inspector of the seventeenth bituminous district; David Young, mine inspector of the fourteenth bituminous district; J. B. Johnston, editor of the *Coal and Coke Operator;* R. H. Heath of Homestead, Penn.; Hugh Gibbs, inspector for the Pittsburg-Buffalo Co., Canonsburg, Penn.; H. D. Thompson, superintendent of the Pittsburg Coal Co., Willock, Penn.; and Dr. McKnight, of Willock, Penn. David Young, of Freeport and T. A. Jackson, of Curtisville, were invited guests.

It is intended to make these meetings an annual affair and much credit is due John I. Pratt for bringing the mine officials together to discuss various mine problems of the day.

Water Purification for Collieries

When water which is possessed of temporary hardness, is boiled or brought near the boiling point, carbonic acid gas is given off and carbonates are precipitated. This treatment suffices if there is no permanent hardness or other impurity to be dealt with but when permanent hardness is present, the water must be chemically treated. In the heater-softener, made by the Eriths' Engineering Co., of London, the use of lime is dispensed with and the arrangemen of the apparatus is as shown in Fig. 1. The supplies of cold water and soda solution are delivered together into a trough near the top of the upright portion of the apparatus, whence the water overflows onto removable trays, and finally falls into the settling chamber. At the same time, exhaust steam is delivered through the oil separator in the upper part of the shell surrounding the trays, and any excess of exhaust steam that there may be, escapes through a vent in the top of the shell.

Steam at atmospheric pressure is capable of heating the water up to about 210 deg. F., and the air and carbonic acid gas in the water are driven off through the vent pipe, a large proportion of the carbonates and precipitates being delivered at the bottom of the settling chamber. Moreover, the soda ash solution, which removes the sulphates, chlorides, and acids, has an accelerated action due to the heat. The water from the settling chamber passes upwards through a horizontal filter.

At the side of the settling tank will be seen a water space in which is located a float for controlling the admission of cold water and soda. The surface of the water in the settling chamber is occasionally flushed over in order to remove the scum due to oil from the oil separator. This is accomplished by admitting an excess of cold water and the portion thus flushed off passes into a trap or water seal. It will be seen that back pressure cannot occur with this arrangement and there is no danger of choking from deposits. The travel of the water after passing over the trays still gives plenty of opportunity for precipitation, and the low cost of soda ash, which is the only reagent used, makes the process inexpensive.

Combined Heater and Softener

The Paterson Engineering Co., Ltd., have a large number of water purification machines working in connection with coal mining plants and the majority of these are arranged for the utilization of exhaust steam from hoisting engines, haulage engines and other steam driven auxiliaries. Fig. 2 shows a type of apparatus in which the supply of hard water is controlled by a float in the feed-pump suction tank and is led through a chemical regulating apparatus, which measures it continuously by means of a narrow vertical discharge weir.

Special Correspondence

Water softeners which make use of waste heat, and combined preheaters and softeners are frequently installed. Iron salts require special apparatus for their removal. Aluminum possesses remarkable properties in connection with the softening of water, which are not, as yet, thoroughly understood. The third of a series of articles on water-purifying processes and apparatus.

A large float controls the position of two tapered valves discharging the softener reagents. The level of these valves is kept constant by ball cocks connected to the chemical storage tanks. The hard water and reagents are thoroughly mixed in a mixing tray before passing through a water seal into the heating chamber. The exhaust steam passes through a preliminary grease separator (where the oil from the engines is removed) to the heating chamber. Here it passes through the trays in a counter-flow direction, finally escaping to the atmosphere.

The heating trays are constructed of light sheet steel and are easily withdrawn for cleansing purposes. The water falls from the distributing box into the center of the top tray. Owing to the great length of the tray the water overflows the edges in exceedingly thin films, which cling to the underside and drop from the center into the middle of the tray immediately below. After working its way to the edges of the second tray it again overflows onto the underside and drops into the middle of the third tray and so on. By this method exhaust steam comes into contact with the films of water and the temporary hardness is removed without the aid of chemicals, by driving off the carbonic acid gas and precipitating the lime salts.

For the removal of the permanent hardness, sodium carbonate is necessary, and this is added through the Paterson measuring gear in accurate proportion to the amount of water passing. The heated and softened water passes into the precipitating chamber where the bulk of the impurities settle out, final purification being effected by double filtration through wood fiber. One objection to the open-type exhaust heater is the contamination of the feed water by oil. This is overcome in the Paterson apparatus by the addition of sulphate of alumina which coagulates the oil and fine suspended matter into tangible masses, readily arrested by the filtering medium.

Apparatus for Removing Iron Salts

Reference was made in a previous article to the removal of iron salts from mine water. The plant referred to, was an automatic self-cleansing filter erected by Messrs. Royles, Ltd., at the Tyldesley colliery for removing ochre colored impurities due to the presence of iron compounds in the water, a clear effluent resulting. Messrs. Royles have also developed a special type of eliminator for underground waters containing bicarbonate of iron which as soon as it is exposed to air is changed into iron oxide causing the water to assume a reddish brown color. Deposits of such sediments are apt to choke pipes and tubes and water thus affected is hardly suitable for either boiler-feed or for bathing and cleansing purposes. A brief note concerning this iron eliminator will therefore be of interest to colliery engineers who have to deal with this particular form of impurity.

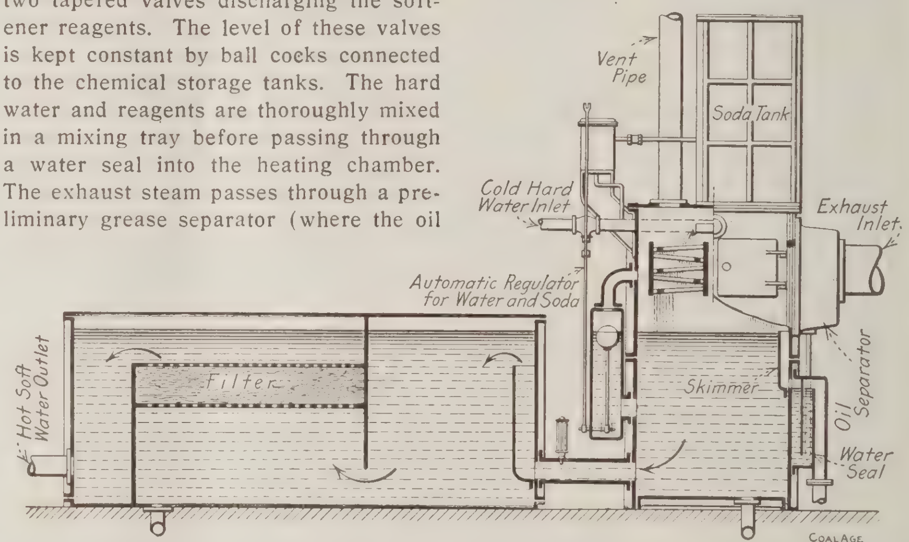


Fig. 1. Eriths "No Lime" Feed-water Purifier

The device is illustrated in Fig. 3 and consists of a spraying tank *A*, coke tower *B*, and a gravel filter which is periodically cleansed by means of air. The untreated water flows into the spraying tank, the bottom of which is perforated with small holes that allow the water to pass through onto the coke bed beneath, in the form of a fine shower. Water and air are thus thoroughly mixed and the absorption of oxygen causes the precipitation of iron oxide. This precipitation is continued throughout the passage of the water in fine streams over the coke, as the sides of the coke tower are perforated to admit more air. A coating of iron oxide speedily covers the coke, and this accelerates the separating action.

From the coke tower, the water passes in the form of a fine shower onto the gravel filter where the iron oxide remaining in suspension is arrested and finally the water is delivered at the point *D* in a purified condition. When the filter has to be cleaned, the mud valve *E* is opened to the drain, and the air blower *F* forces in a supply of air at the same time that water is admitted to the lower side of the filter. Energetic flushing of the filter is then maintained for a few minutes and the muddy water is drawn off through the mud valve.

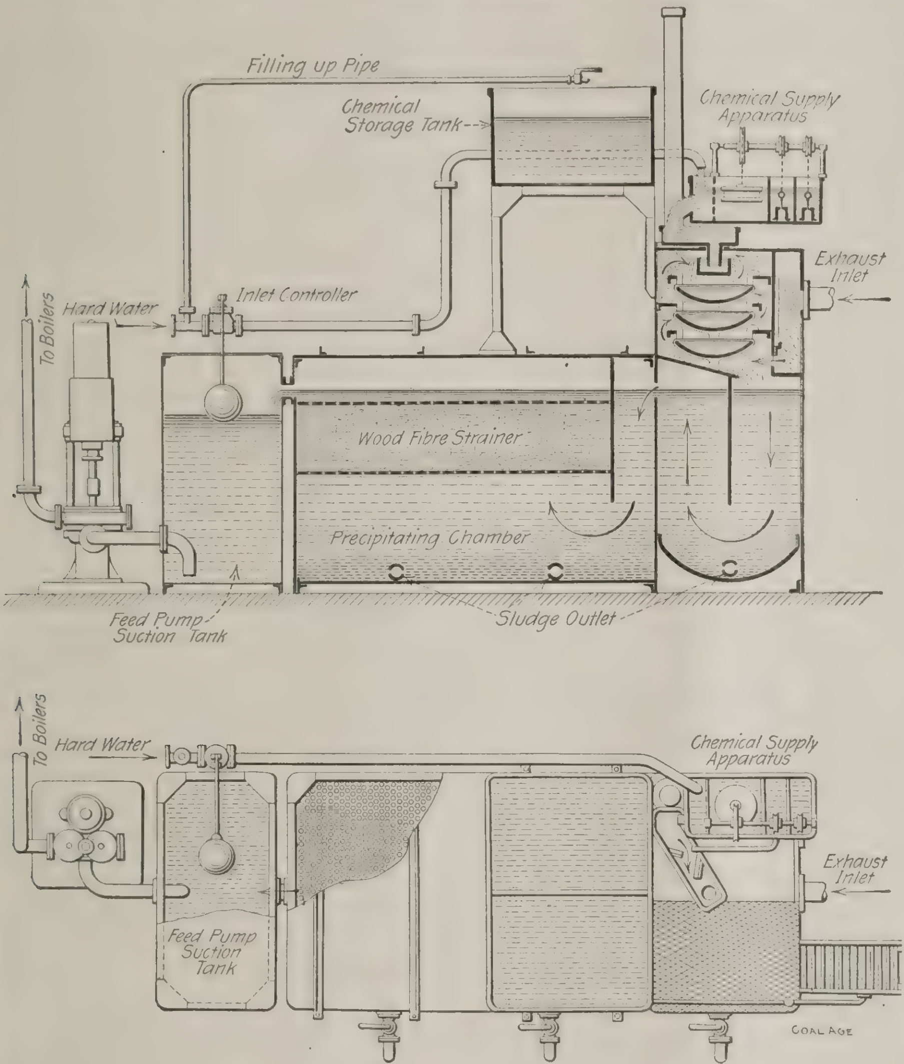

Fig. 2. Combined Purifier and Open-type Heater

Remarkable Property of Aluminum

Mention was made also of the remarkable action of aluminum on water, in connection with preventing hard scale in boilers, and some reference should be included to the Neff-Brandes apparatus which has been installed in Kainscht, near Meseritz, Germany. The boiler at this plant, used for driving air-pumping engines, was supplied with water from a ditch running over a neighboring mine. This water was of a particularly hard quality, the scale formed on the boilers being excessive. The Neff-Brandes apparatus, when installed, not only destroyed the adherent boiler scale, leaving in its place a scanty gray powder, the greater part of which was completely removed from the boiler by flushing out, but the pressure of steam was thereafter maintained with ease, and the boiler plates were kept in good condition. Dry steam of a bluish tint was obtained instead of steam having a gray appearance, indicating excessive moisture.

The Neff-Brandes apparatus has been brought to England under the name of the "Luminator" treatment. The operation consists solely in running the water down the channels of a steeply inclined corrugated aluminum plate, and the water after this treatment is passed directly into the boilers. No reagents of any sort are added. The action of the process, so far as at present can be determined, is as follows:

The surface of the aluminum plate, being kept clean and active by occasional scrubbing, slowly disintegrates and forms an extremely fine powder of aluminum in the colloidal state. This fine powder is washed off the surface of the plate by the water passing over it at a high velocity and is carried with the feed water into the boiler. In the boiler, these extremely minute metallic particles, which remain in suspension in the water, form nuclei for the evolution of carbonic acid gas and also for the crystalization of the carbonates in the water. This crystalization thus occurs on the aluminum particles instead of on the boiler surfaces and there is finally deposited a soft and non-adherent mud.

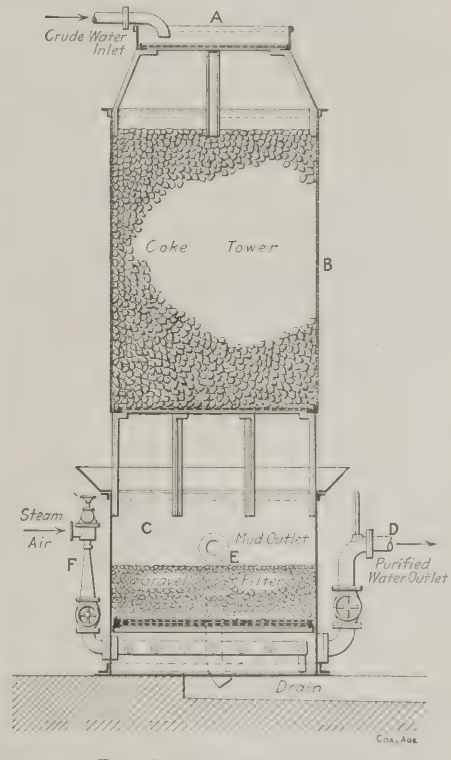

Fig. 3. Iron Eliminator

When the water contains permanent hardness the effect on the sulphates is not definite. The sulphate crystals form in the ordinary way but are separated from one another by the non-adherent carbonate mud, and are thus prevented from forming a close scale. This is briefly the theory of the operation of the process, although there are undoubtedly other actions occurring which have not yet been fully demonstrated by experiment.

Review of Iowa Mine Explosions

By R. T. Rhys*

Answers to numerous inquiries received in regard to the Iowa practice of slowing down or stopping the ventilating fan previous to firing shots in coal mines. Brief review of mine explosions in Iowa: First, in mines in which the ventilation was not reduced when firing; and second, in mines where the ventilation was so reduced. Comparative results and conclusions.

From the inquiries I have received of late it seems that the Iowa method of slowing down the fan at firing time is receiving considerable attention in other states. In the discussion relative to the advocacy of this method the following questions have been frequently asked:

(1) What is the practice, in Iowa mines, regarding the speed of the fan at firing time?

(2) Has the slowing down of the fan at firing time put a stop to explosions and windy shots in Iowa mines where this practice has been observed?

(3) Does experience in Iowa mines show that the slowing down of the fan at firing time reduces the danger, or the probability that an explosion will occur?

(4) Does experience in Iowa mines show that the slowing down of the fan at firing time lessens the force of an explosion and makes it less destructive should one occur?

My answers to the above questions are deduced from the official reports of Iowa explosions, and from my own personal observation and experience. They are as follows:

(1) The general practice in this state has been for the past several years and is today, in all new mines or mines not extensively developed, to stop or slow down the fan, a little before or at firing time. In practically all our more developed mines, however, the fan is allowed to run at its usual rate of speed; that is to say, there is no change made in the speed of the fan, at firing time.

After the Pekay and Cedar mines explosions the people of our state were in a receptive mood to adopt any practical measure that promised to diminish the danger of an explosion, or make it less destructive should one occur. Some of our leading mining men at the time strongly advocated the slowing down of the fan at firing time as a measure of protection; and, inasmuch as the remedy proposed was an easy one to carry out, entailing no expense to the operator or loss of wages to the miner, it was not long before some mines adopted the plan suggested. By the end of the year 1902 the practice of slowing down the fan at firing time had become quite general throughout the state, and has been adhered to ever since. Whether right or wrong the belief in its protective value is such that it would be almost impossible to secure shotfirers in new mines, especially during the cold season, unless the fan is stopped or slowed down at firing time.

(2) I can positively answer this question by saying that it has not. It is only fair, however, to say that no one, in this state, claims that it does.

(3) To this question I shall not reply either in the affirmative or the negative. I am seeking for and ready to receive proof either for or against the practice in this state. I think I am correct in saying that should I or some one else answer "yes" or "no" to this question it would only be a matter of opinion. No one yet, to my knowledge, has been able to show positive proof that the practice of slowing down the fan at firing time has prevented a single explosion, in this state, or that the practice has caused one.

(4) To compare explosions in Iowa with those in other states, even though there be a similarity of conditions, may often lead to wrong deductions. It seems to me that to arrive at right conclusions, Iowa explosions that have occurred in mines under one practice of ventilation at firing time, should be compared with those that took place in Iowa mines under a reversed practice of ventilation at firing time. In other words, to prove which of these two methods is the best and safest practice, comparisons should be confined to Iowa mines, under the two practices. When we do this the claim that explosions in mines where the fan was kept running at the usual speed and the usual quantity of air was circulating at firing time have exhibited greater force and were more terrific than those that occurred in mines where the fan was stopped or slowed down at firing time becomes a questionable one.

Iowa Mine Explosions, Ventilation Not Reduced When Firing

(a) The first explosion in Iowa, causing loss of life, was in Pekay mine, Nov. 8, 1892, when three men were killed. The official report of this explosion shows that there was evidence of great force. The fan was running to within a few revolutions of its usual speed; and practically the usual current of air was circulating at firing time.

(b) The explosion in the Cedar mine, Feb. 14, 1893, where eight men lost their lives, took place when the usual volume of air was circulating at firing time; and although the number of lives lost was greater than in the Pekay explosion, yet the extent of the explosion was limited and the damage done to the mine was small. All the men killed were on the entry, going home, and were caught by the blast not far from the seat of the explosion.

(c) The Jack-Oak mine explosion took place Nov. 27, 1894, at a time when the usual volume of air was circulating. One person was killed. The area traversed by the explosion was small and practically no damage was done to the mine.

(d) The explosion at Buxton, mine No. 13, took place March 5, 1907. One shotfirer was killed. This mine was an extensive one, and the fan was not slowed down at firing time. The explosion traveled only a short distance and did but small damage.

(e) The explosion at Lockman, mine No. 3, took place Jan. 4, 1910. One shotfirer was badly burnt. The usual current of air was passing at firing time. The extent of the explosion was small and no damage was done to the mine.

I have thus named every explosion of importance recorded in the biennial reports of the state mine inspectors that have occurred in mines where the usual current of air was passing at firing time. From these reports it is plain to the impartial reader that the Pekay explosion was the only one that exhibited evidence of great force. Also, in comparing these explosions it should be remembered that in the Pekay explosion five and one-half kegs of powder were exploded, which added greatly to the force of the explosion. This, everyone must admit, was a great factor in extending the area and augmenting the force of the explosion.

Iowa Mine Explosions, Ventilation Reduced When Firing

I shall now give a list of all the important explosions that have taken place, in the mines of this state, where the fan was stopped or slowed down before firing time.

(f) The explosion at Cleveland, mine No. 4, Jan. 5, 1901, when two shotfirers were killed, was marked by evidence of intense heat at the point of origin, and the initial force was great. Large rocks weighing several hundred pounds were picked up and carried quite a distance. The force of this explosion extended out along the main entry to the hoisting shaft through which it ejected dense volumes of smoke and dust to the surface. The fan in this case was running at a slow rate of speed at firing time.

(g) A second explosion occurred at Cleveland, mine No. 4, Feb. 5, 1901. The

*State Mine Inspector, District No. 2, Ottumwa, Iowa.

two shotfirers were found in an unconscious state by the rescuing party but recovered after being removed to pure air. This explosion originated at a point less than 50 yd. distant from the explosion of Jan. 5. The explosion left scarcely any sign of great heat, and created no unusual disturbance in the vicinity of its origin. Its initial force apparently was less than the first explosion named; but it gathered strength and became more destructive on its way out. Doors and stoppings that the former explosion failed to damage were destroyed by this explosion. A larger volume of smoke and dust was ejected from the hoisting shaft; and, while no life was lost, it was an explosion that exhibited tremendous force. much greater than the first one named. The fan in this instance also, had been slowed down at firing time.

(h) The most disastrous mine explosion in the history of Iowa took place at Lost Creek, Jan. 24, 1902. Twenty lives were lost. No explosion in this state has ever exhibited as great a flame as this one. It was a terrific explosion, and yet the fan in this case also was running at a slow rate of speed at firing time.

(i) Two shotfirers lost their lives in the Hocking-mine explosion, Feb. 18, 1902. I am not able to state the extent and the force of this explosion; but am informed that it was the practice, in this mine also, to slow down the fan at firing time.

(j) The explosion at Foster, Jan. 25, 1904, when two shotfirers lost their lives, was a light one, and the force of the explosion was comparatively small. The two shotfirers had undoubtedly erred in the manner of lighting the shots and also in the selection of a proper place of safety. The fan was stopped at firing time.

(k) The fan was stopped at the Dempster mine, when, on Nov. 1, 1906, the force of the blast of an explosion blew both cages up the shaft and against the sheave wheels, killing two men.

(l) The fan was stopped at Buxton, mine No. 15, when one shotfirer was killed by the force of an explosion, Feb. 25, 1910.

(m) At the explosion at the Regal mine, Jan. 15, 1912, when two shotfirers lost their lives, the fan was running at a very slow rate of speed at firing time. While no great damage was done to the mine, yet I doubt if any explosion in this state has showed evidence of a greater force.

This completes the list of all the principal explosions that have taken place, under both practices, in the Iowa mines, from the first serious explosion in 1892, up to the present time. In comparing these explosions I have named, first, those that occurred under one practice, and then those that took place under the opposite practice. I think every unprejudiced reader will agree with me that so far as the records of mine explosions, in Iowa, are concerned, the claim that slowing down the fan at firing time lessens the force of the explosion and makes it less destructive is not sustained, but is decidedly against this theory.

Explosion at Merritt, B. C.

By Chas. Graham*

Mixed lights and a single-entry system sufficiently explain the Merritt explosion. The flame, checked by a lack of fuel in the intake airways, was unable to travel more than a few feet along the right-hand split, with the result that eleven men were saved.

*Superintendent, Nicola Valley Coal & Coke Co., Middlesboro, B. C.

No. 3 Mine, operated by the Diamond Vale Collieries, Ltd., is located about one mile east of the town of Merritt, on the Nicola Valley branch of the Canadian Pacific Ry. The coal seam is about 4 ft. 6 in. thick and contains two bands of rock. The first band, about 12 in. from the floor, is 6 in. thick. The second, about 33 in. above the floor, also measures about 6 inches.

Two slopes have been driven from the outcrop directly to the dip, and at a point 300 ft. down, a left level has been turned off. The bed at this point is dipping at an angle of about 40 deg. About 50 ft. further down, another level has been driven to the right, and still further down a second level to the left has just been started.

The number of men working in the mine was normally only 20 at the time of the explosion, for the mine was not fully developed. Of this number, 18 miners were actually at work on the date of the disaster—six in the first left level, one in the second and the remainder in the right level. The six miners in the left level and the fireboss, who was traveling along the same heading, were killed; all the others escaped.

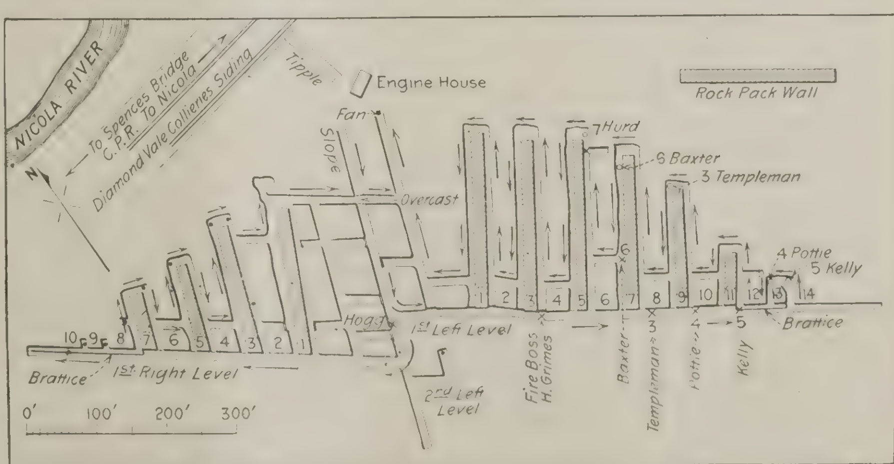
The mine was worked on the room-and-pillar system, with rooms 40 ft. and pillars 36 ft. wide. The room necks were double and about 20 ft. long. The rock from the coal was packed in the center of the room and just filled the space between the chutes, which were built along each rib. The roof is of a hard sandstone, and usually stands without timber.

The Explosion

The explosion occurred at about 9:45 a.m. on the morning of Mar. 7, 1912. A dense cloud of black smoke issued from the mouth of both slopes, and the tipple man, working at the mouth of the haulage slope was blown a short distance by the force of the explosion, but escaped injury. The fan, which was situated in the mouth of the drift, was blown about 25 ft., and the driving belt about 200 ft. The smoke-stack on the boiler was also blown down.

The explosion originated in chutes 13 and 14 of the left level, which were the last openings in this heading. These chutes were connected, but no connection had been made with chute 12. The air was carried by brattice cloth along the level to the mouth of No. 14.

The explosive force generated was not great, and there was little damage done to the mine, the greatest evidence of force being afforded by the action of the



Plan of Diamond Vale Colliery No. 3, Showing Where Men Were Working

fan, which was blown out of the mouth of the return airway. The tops had also been blown off the packs in the rooms.

Cause of the Explosion

Gas had evidently been found in chutes 13 and 14. for the two miners in this room had been provided with safety lamps. These lamps were found hanging on props in their respective chutes. The miners had apparently been using their naked lights on the heading, and one of them had evidently gone up along the chute and taken his naked light with him.

Fan Dislodged by Explosion

Main Slope Diamond Vale No. 3

The explosion confined itself to the first left level and the main slope. The flame turned down the main slope toward the right level, for the rope rider and a pusher who were on the siding were severely burned. There is much water on the floor at this point, and the flame did not travel any further. All the men who were working in this level escaped uninjured, with the exception of the two men mentioned. These men recovered from their burns.

The cause of the explosion was undoubtedly an ignition of the gas in chutes 13 and 14 of the left level by a naked light. The explosion was extended in some degree, however, by coal dust. No powder is used in the mine, but much dust is found, especially in the chutes, due to the breakage of coal as it descends the steep pitch.

Rescue Work

Notice of the explosion was telephoned to the office of the Nicola Valley Coal & Coke Co., at Middlesboro, about two miles distant. I immediately got together a crew of men and loaded the Draeger apparatus on a switch engine. My party was taken over to the Diamond Vale mine. In the meantime, Supt. Browitt, of the Diamond Vale Collieries, Ltd., had gone into the mine and was endeavoring to reach the men. Upon my arrival, Mine Foreman D. Brown, Thomas Archibald, of the Nicola Valley Coal & Coke Co.'s staff, and I went into the mine with the apparatus on. We proceeded along the level and located three of the bodies, the first one being that of H. Grimes, the fireboss.

There was a certain amount of natural ventilation and the level seemed clear. We returned to the slope, took off the apparatus and got together a number of men and went along the left level and brought out four bodies. A fifth was found on the slope below that level. An attempt was made to recover the two remaining bodies up the chutes, but the party was driven back by the afterdamp. Stoppings were repaired temporarily, and it was not until the following afternoon that the remaining bodies were found and brought out. All of the men who escaped, came out of the mine unaided.

In the mine plan, the double lines show where dirt stoppings were erected; single lines, which cross openings, denote curtains. Crosses show where the bodies were found, and the open circles show where the men worked. It is clear that several of them tried to escape after the explosion and fell dead on their way out. The black dots show where those men, who were not killed, were working when the explosion occurred.

Operation of Diamond Vale Collieries, Ltd.

A cheerful disposition may brighten the day underground even though it cannot bring real sunshine.

Safeguarding the Use of Electricity in Mines

By Hartley M. Phelps*

Investigations of great moment to mine workers and operators, looking to the elimination of explosions, and consequently the saving of human life, are being conducted by the Electrical Section of the Bureau of Mines at its experimental station in Pittsburg. It is known that the results attained so far have been important, although the details have not been made public, as it is the policy of the government not to divulge such information prior to its appearance in the regular bulletins and monographs of the Bureau.

Investigations are being made along the lines of determining the danger of igniting gas by the indicators of inclosed fuses and by incandescent lamps when broken in gaseous atmospheres. Tests are also being made of explosion-proof apparatus and of the insulation of electrical conductors. Furthermore, preparations are being made to investigate the action of electric sparks and arcs in the presence of coal dust; the danger of using electricity in the vicinity of explosives; and to make examination of electrical shot-firing devices, and devices for the protection of trolley wires.

According to H. H. Clark, who is in charge of the Electrical Section at Pittsburg, a great many explosions in coal mines are due to electricity, and many more explosions originate from this source in the United States than in England, for instance, where strict legal regulations hedge in the use of electricity in coal mines. Mr. Clark points out that the equipment of mines involves a distinct branch of electrical engineering. The conditions underground are quite different from those on the surface. Not

*P. O. Box 73, Forbes Station, Pittsburg, Penn.

only is it here more difficult to install and properly maintain electrical apparatus, but, unless suitable precautions are observed, the presence of such equipment in mines adds danger to a calling already hazardous. In addition, danger to electrical installations comes from falls of roof, coal and rock, and from the fact that acid waters and dampness make insulation difficult. The need of only temporary installations, thus limiting the investment, further adds to the risks to life. Moreover, many mine workers are prone to ignore the rules made for their benefit.

The three principal dangers arising from the use of electricity in mines are: shock, explosions and fires. The chief sources of shock are trolley wires and other bare conductors. Many explosions result from sparks and arcs occurring in an atmosphere of inflammable gas or dust. Sparks big enough to ignite gas are produced when a motor is started rapidly or operated under a heavy load; or when a circuit, carrying current, is opened, or becomes grounded. It requires a much larger spark to ignite bituminous coal dust, but such flashes might be caused by short circuits on conductors carrying a large current, as in the event of a trolley wire failing.

Tests are being made by the bureau to determine how small a flash will ignite gas or coal dust, the temperature of the spark being the crucial factor.

Two Testing Galleries

There are at Pittsburg two galleries for testing electrical equipment in the presence of gas. The smaller is in the laboratory and consists of a boiler-iron box, with connections for admitting gas and air, and having heavy plate-glass observation windows, and openings for relieving the pressure of an explosion. A small motor-driven centrifugal fan mixes the gas and air and causes the mixture to circulate. Devices are installed for determining percentage of gas. In this gallery small sparks and lamps are tested.

The larger testing gallery is a tube designed to simulate a section of mine entry. It is of boiler iron, 30 ft. long and 10 ft. in diameter, and is horizontal, being set in a concrete bed and partly filled with concrete to form a floor upon which apparatus can be set up for tests. Seven and one-half feet from either end, a diaphragm of heavy paper may be inserted to relieve the pressure from an explosion before it becomes dangerously heavy. Entrance to the shell is made through a manhole between the heads. Heavy plate-glass windows are set in the sides of the gallery. A fan mixes the gas and air and an indicator is provided to show the amount of gas present. In this gallery explosion-proof motors and switches and other large apparatus are tested. A special tube is being built for investigating the ignition of coal dust by electricity.

In testing lamps, these are placed in a gas-tight receptacle, filled with a mixture of gas and air combined in proportions most sensitive to ignition. The lamps are lighted and the filaments brought into contact with the gaseous mixture in three ways. First, by smashing the bulbs, thus bringing the mixture in contact with the broken filaments. Second, by snipping off the tips of the bulbs, which usually does not break the filaments, as the velocity of the entering gas is less than in the first method. Third, by puncturing a small hole in the neck of the bulb, which prevents the entering gas from impinging directly upon the filaments, and therefore rarely breaks them.

Explosion-proof motors and switches are tested in much the same way, as it is the flame-proof quality of the casing that is in each instance the point at issue. The atmosphere provided outside the casing is a combination of methane and air most sensitive to ignition.

The experiments relating to the action of acid mine waters upon the insulation of electrical conductors have for their purpose the standardization of methods for future tests. The action of such water is determined by means of insulation-resistance measurements, and by high potential tests.

In making tests of inclosed cartridge fuses in explosive gas, a representative of the manufacturer of the fuse may be present. Those fuses passing the tests are listed for the benefit of the state mine inspectors.

Suggestions and Recommendations

Among the various recommendations made by the Bureau as to installation of electrical equipment may be mentioned the following: All high- and medium-pressure lines and apparatus should be marked at frequent intervals "Danger," and the voltage given. Low-pressure or lighting wires should be marked "Caution," and the voltage stated. Machine terminals should be protected. Lightning arresters should be placed on transmission lines from the generator stations to the mine entrance. High-pressure lines in underground roadways should be lead-covered cables, armored or unarmored. Insulation should be non-hygroscopic and as acid-proof as possible. Trailing cables for portable motors should be especially flexible and well protected. Automatic trolley switches and danger signals should be used.

One important recommendation is: Before any coal-cutter motor is in operation more than a half hour, the mine roof should be examined unless otherwise specified by the mine foreman.

Current and power circuits should not be used for shot-firing. Gaseous mines should be examined daily by firebosses before work is started, the gas to be detected by safety lamps under normal ventilation. If gas is found in dangerous quantities no current should be turned on any circuit for at least 24 hours.

All main cables should be kept away from explosive gases. The switches and fuses should be inclosed in explosion-proof boxes and break under oil. The current-carrying parts of direct-current motors should be surrounded by explosion-proof casings unless the motors are in rooms separately ventilated by intake air. The carrying of tools near wires and the placing of powder near conductors should be prohibited, or guarded against.

The Bureau deplores the absence of uniformity in the installation of electrical equipment in mines, but affirms that the various states are taking a lively interest in an effort to secure suitable regulations, although an admirable set of rules was rejected by the Pennsylvania legislature two years ago.

Coal of Southern Nigeria

In regard to the deposits of coal in Southern Nigeria, West Africa, Consul William J. Yerby reports that the governor, in his recent annual address said that the work of the mineral survey during the year has been concentrated on the further examination of the extensive deposits of coal at Udi, which are found to stretch more than 50 miles to the north of that place. The tests and analyses carried out by the government have proved that the surface samples give results equal to two-thirds that of the best Welsh coal. It is reasonable to expect that if the seams are worked the coal that has not been exposed to the weather will be of still better quality.

The question of the construction of a railway to connect this coal field with the river port of Onitsha is under consideration. It is hoped that sanction for the construction of this line may be given, as the importance of cheap fuel to the two Nigerias is great, their combined railway system being already over 800 miles in length. Besides the railway requirements, there is urgent necessity for coal to supply river and ocean shipping.

The lignite deposits to the west of the Niger are also valuable and in at least one locality vary from 10 to 15 ft. in thickness. The total trade of Southern Nigeria in 1910 exceeded $55,000,000, whereas it was scarcely over $20,000,000 in 1900.

The possibilities of profitable mining and export of coal from the Federated Malay States is referred to favorably by the chief secretary of the government in his annual report, just submitted. The deposits of coal are extensive and convenient, the serious question about the matter being with respect to quality. A satisfactory coal supply in those States would be welcomed by shipping in that portion of the world.

Colliery Mine Car Construction

By A. T. Shurick

This is the first of a series of articles which will appear on this much neglected subject. The present paper discusses the general conditions for determining the proper shapes and sizes, and includes a few preliminary remarks on car wheels. The second installment will follow at an early date.

With the advent of large corporate interests into the coal industry, involving extensive investments and heavy tonnages, the mine-car expense item is being more carefully studied. The attention of trained and capable engineers has been concentrated on this feature, and important strides in the design and construction of cars have been made in the last decade.

As a result of the keen competition existing in the coal industry today, it is not unusual for a difference of one cent per ton in the cost of mining, to determine whether a mine may work, and in reducing operating expenses to a minimum the mine manager will doubtless put his finger on the mine-car expense account first. Not only must this be considered from the standpoint of first cost, but in upkeep as well. The expense, incident to continued oiling, and the wear and tear (an item of particular importance in mine cars) are the first points to consider in the well designed car.

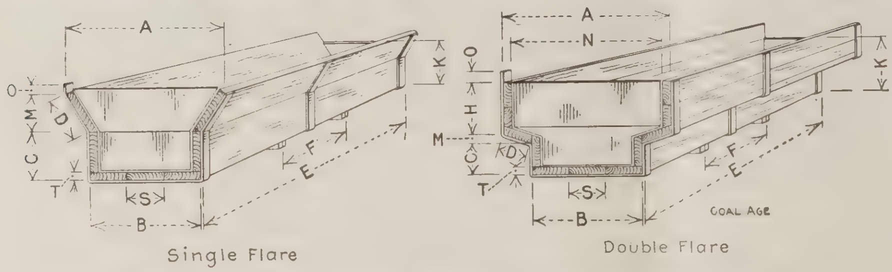


Fig. 1. The Two General Shapes of Cars in Common Use

Preliminary Considerations

It is the purpose of this paper to discuss only the composite, frame cars, and to confine the discussion more particularly to the features of interest to the active colliery engineer.

The steel car is coming rapidly to the front and may even in time entirely supersede the wooden car, but that cars of this type have serious disadvantages for work of this character is generally conceded. Thus, for example, the results of a runaway on a heavily pitching slope may be considered with both types of cars. An accident of this kind, on a slope laid with good track, will probably result in the more or less complete destruction of the entire trip, especially if the cars are loaded.

With the wooden car a certain amount of salvage will be possible, as the individual pieces of the iron framework are comparatively easy to recover and reshape. In the case of the steel car the problem will not be so simple, since the average mining plant is not equipped with proper facilities for handling work of this character*.

*For further discussion of this point the reader is referred to Coal Age, p. 379.

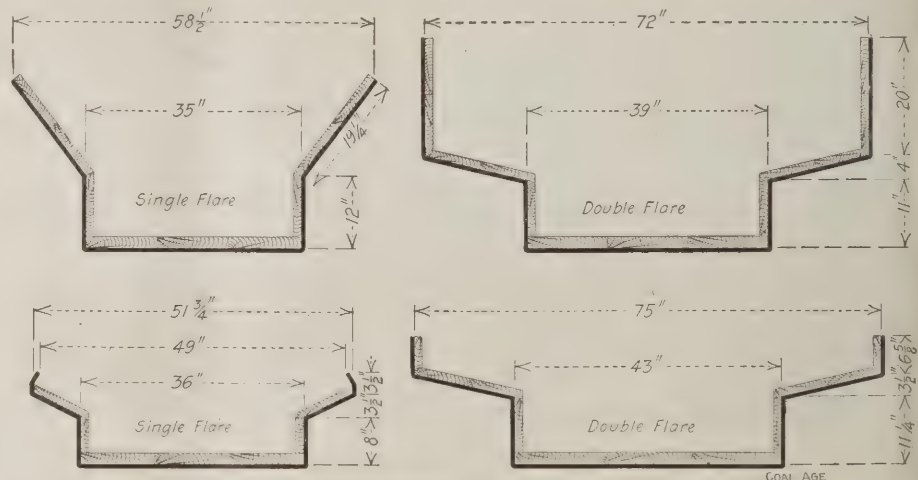

Fig. 2. Typical Sections of Small and Medium Capacity Cars

Rules, formulas, etc., for the proportioning of material, as in machinery design, appear to be entirely unknown here. Many companies design and assemble their own cars, ordering the different irons as required. The ultimate and finally accepted design in such instances is often only arrived at after years of experimenting on the "cut and try" method, but that this eventually gives a thoroughly practical car is hardly to be questioned. A superintendent working along these lines finds for example, only after a number of years, that a certain iron is too light and revises his design accordingly.

That a method such as this would be productive of apparent inconsistencies and freak designs was inevitable. Thus for example may be noted the open derision expressed by a well known mechanical engineer, because of the excessive material (according to his views) used in a coupling at a certain colliery. This coupling had been evolved from 12 years' experience, and had he known the number of wrecks, due to runaway trips, costing from $500 to $1000 each, not to mention the delay to the mine, which had been required to bring about its adoption he would have been less abrupt in his criticism.

Shapes

The first problem confronting the mine car designer is fixing the general overall dimensions and shape. The shapes may be roughly classified as belonging to one of two types, the single or double-flare, as shown in Fig. 1 herewith. In addition to these there is the square, box type, now confined almost entirely to the anthracite field.

Referring to Fig. 1 the overall width *A* will of course be determined by the minimum widths of the haulageways. The overall length *E* is limited by the track curves and to a certain extent by the wheel-base *F*. The bottom width *B* is dependent entirely on the track gauge and the overall height will be determined by the thickness of the seam.

The choice of the single or double-flare type is mostly a matter of taste and is a subject still open for discussion. There are, however, certain features which should be considered in this connection.

When the seam is high, providing ample head room with no additional cost, the square box type anthracite car may be used to an advantage because of the simplicity of construction. The double-flare type is adapted more practically to a soft, friable coal having few lumps, while with a coal making numerous lumps, these can be used to build up around the sides and ends, thus eliminating the necessity of the extra vertical board.

To one who has ever helped lift a single-

flare car on the track by the usual method of placing the back and shoulders under the flare-board and later tried the same with the double-flare type there will remain no question in his mind as to the superiority of the single-flare car. In addition to this the extra space on the outside of the single-flare car greatly facilitates spragging, particularly in a narrow entry.

Some Typical Cross-sections

The variety of cross-sections for cars is unlimited and selection of the proper shape is governed entirely by the physical conditions of the seam to be worked. Eliminating all designs of a "freak" nature the principle and typical cross-sections of mine cars are given herewith. The examples selected show the maximum and minimum dimensions as to height and width of accepted designs of cars; the designs are in every case of cars which have demonstrated their practicability by a number of years of service.

Two types of low vein cars are shown in the lower part of Fig. 2. On the left is a single-flare car only a little over 4 ft. wide, and with a maximum height of body of but 15 in. This is an extreme exaggeration of this type and may be likened much to the sled used in some parts of Europe for conveying coal along the face to be dumped into the mine car. The flare board comes out nearly flat, completely covering the wheel, which would make spragging difficult, although in a car having such an obviously small capacity as this, the necessity of spragging would not be so urgent.

On the lower right hand side of Fig. 2 is shown a type of low vein car over 6 ft. wide and less than 2 ft. high. This car has an enormous capacity, comparatively speaking as regards low vein cars generally, but would be adaptable only where the best roof conditions prevail. It is of the double-flare type, having a short 6-in. vertical board around the top, which of course adds materially to its carrying capacity. The broad, flat flare of 16 in. on each side would, in this case, prove a very serious hindrance to spragging. The difficulty of providing adequate support for this flare, to insure its retaining its proper shape under the everyday conditions of hard usage around mines, would be another objection. An illustration of a typical low vein car is shown in the accompanying halftone, Fig. 4.

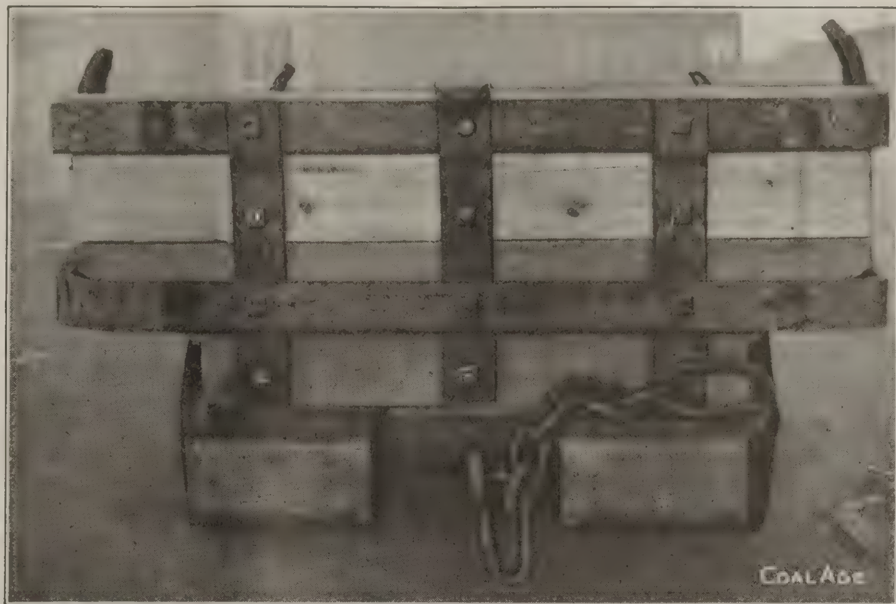

Fig. 4. End View of Low-vein Car, Showing Door

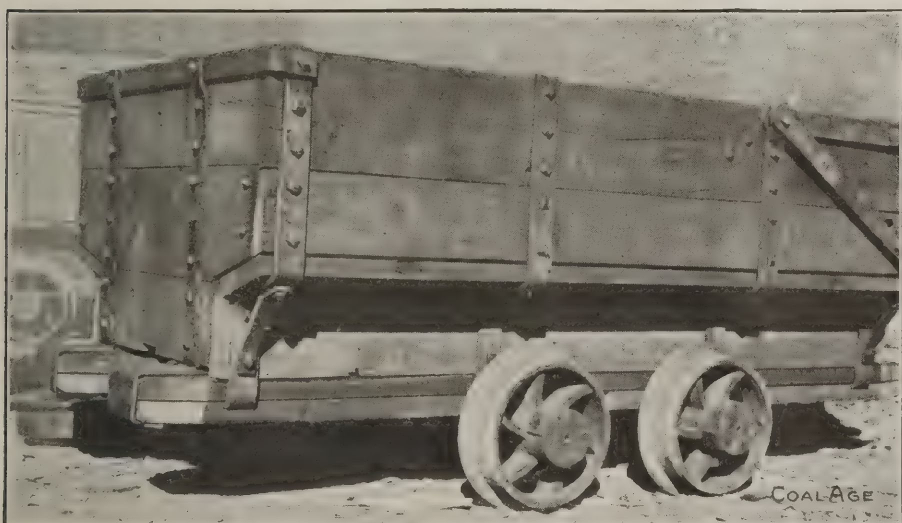

Fig. 3. A Double-flare, Medium Capacity Car

The two upper sections in Fig. 2 are examples of the typical medium sized cars, and an illustration of the same type is shown in the halftone, Fig. 3. On the left of Fig. 2 is shown the single-flare type having a width of nearly 5 ft. and an overall height of body of about 2 ft. 4 in. This section is one of the most popular in use on the medium, or medium-small cars in the bituminous fields. The single flare with its rather acute angle, makes the car easy to sprag and handle under all working conditions, and at the same time adds appreciably to its capacity. On the upper right-hand side is shown a rather large, double-flare car of good capacity. This car has an overall width of 6 ft., and a body height of nearly 3 ft. While the broad, flat flare adds appreciably to the capacity of this car, as already stated, it is much more difficult to handle, for which reason it does not commend itself so readily to the practical man.

Large Capacity Cars

The larger size bituminous and one of the smaller anthracite cars are shown in Fig. 5. The bituminous types here shown are probably more extensively used than any other class of car, since they are readily adaptable to a 6-ft. or thicker seam, which is probably the average for this country. An illustration of the typical single-flare car of this class is shown in the halftone, Fig. 6. The anthracite operators claim conditions in their mines cannot be compared with the bituminous, and they continue to adhere to the straight box form as shown.

The single-flare bituminous car, shown in Fig. 5, has a maximum width of a trifle less than 4 ft., and a body height of a little over 3 ft. This car has a capacity of 2¼ or more tons of coal, depending on the height to which it is "built up." Larger cars than these are found at times, in fact some districts using them to the exclusion of all others. The opponents to the larger capacity car claim that the difficulty experienced in handling them under the adverse conditions in the mine more than offsets the advantage gained

by the increased tonnage, so this still remains an open question.

The beginning of the flare in these cars may be at any point, providing it is sufficiently high to clear the flange of the wheels, which commonly fit fairly snug against the side of the car. The height should be made such that some commercial size of board will fit, without further trimming, as for instance, 6, 8 or 10 in.; this rule should be followed in the layout

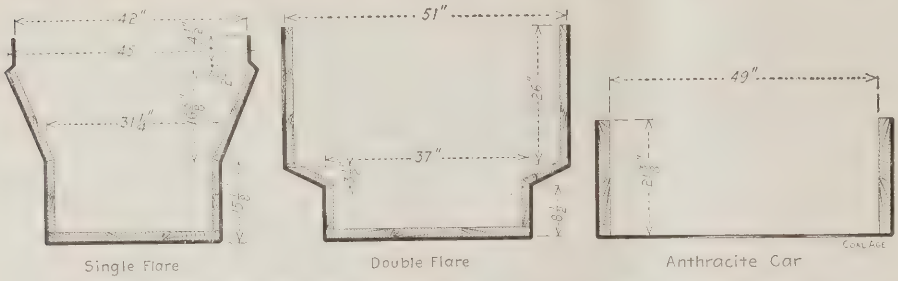

Fig. 5. Large Capacity Bituminous and a Typical Anthracite Section

of all the straight lines of the bands when it can consistently be done within reason.

Car Wheels

The heavy tonnages handled at the modern plants of today necessitate large trips and a comparatively high-speed haulage. In addition to this most of the power required at the mines is usually consumed by the haulage appliances in one form or another. The importance of this subject is, therefore, at once evident, and in no single detail of haulage is it possible to effect greater economies than by the provision of a suitable wheel. This fact has long been appreciated by both the engineer and the manufacturer, and has resulted in a keen competition among the latter until an unusual refinement in design has been attained.

Were it possible to use straight tracks, the mine-car wheel would no doubt be fitted tight to an axle revolving in boxes attached to the car. The sharp curves, essential in all mines, obviously make this impossible since the travel on the outer rail of a curve is so much longer than on the inner that the wheel on the former would have to slide in order to keep up. The advantages of the tight wheel were too great, however, to be completely ignored, and some manufacturers finally evolved the combination tight and loose wheel, thereby overcoming the difficulty due to curves, and making the use of one tight wheel practicable.

But even under these conditions it is still evident that one loose wheel must be used, and since the other presents no difficulties in construction, the discussion of wheels here will be confined entirely to the loose-wheel type.

Car-wheel Material

The first requisite of a good car wheel is the selection of the proper material, and the manufacturers have attained a high degree of refinement in this respect. To insure the best results the chemical analysis of the iron must be exact. Variations of one-tenth of 1 per cent. in the content of some of the ingredients may entirely ruin the wheel, and since no two carloads of pig iron analyze the same, the purchaser of wheels should investigate this feature thoroughly.

Not only must the chemical analysis of the material be perfect, but the method of casting as well. All wearing surfaces must be hard to insure the wheel having a long life. These hard surfaces are attained by means of "chilled castings," in which the sand in the mold is replaced by iron castings adjoining the surfaces to be chilled, the depth of which latter is regulated by the thickness of the iron. While it is a comparatively simple problem to chill the rims, it is not so easy to accomplish this at the same time in the hub. The chemical reaction of the chilling process embodies simply the intimate combinations of the carbon with the iron, forming iron carbide. The result is a product of such hardness that it will cut glass.

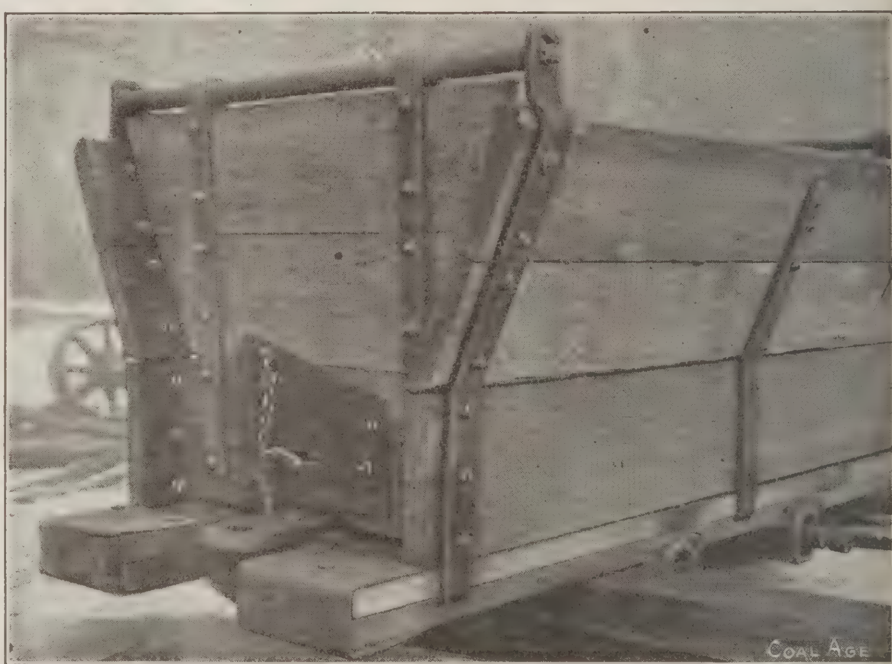

Fig. 6. View of the Door End of a Medium or Large Capacity Bituminous Car

The Mannesman Steel Mine Prop

The Mannesman steel pit prop used in England and on the Continent consists of an outer and inner tube, telescoping within each other. The outer tube is provided with a clamp, which, when loosened, permits drawing out the inner tube to give the required length to the prop. It is then tightened by means of a spanner.

This prop, fitted out with an ordinary cap, is driven into position under the roof with a sledge hammer. It is provided with a ratchet lever and rod by which the clamp is loosened, enabling the miner to withdraw the prop without danger. The safe load for this prop is 16 tons; they neither bend, break or collapse, but in case the load is over 16 tons the prop telescopes until the pressure is removed.

Though the first cost of these props is high, about 30 times that of wooden props, they can, under normal conditions, be used and withdrawn 60 times before repairs are necessary, so that in the end the cost is really about half that of wooden props. The average life of the prop is about five years.

The first cost of steel props is so high that their use at the working face is economical only where every prop is withdrawn and none lost. They are best suited to a moderately hard or strong roof which comes down bodily and breaks in large masses, as this gives a good opportunity for their recovery. They are, however, quite unsuitable for use with a soft, shaly roof, or with fireclay, which breaks easily.

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

The Cement Gun

The cement gun has been advocated by mining experts for use in the mines to fill up crevices in the strata and to make a smooth surface on which the coal dust cannot rest. In the French mines several thousands of feet of concreted galleries have been constructed by ordinary methods of concreting. The ease with which they are kept clean of dust is an argument in their favor. But concreting with the use of forms is expensive and the cement gun methods are preferable. It is needless to point out that the cement gun has numberless uses in other building construction around the mines.

The Invention of a Taxidermist

At a meeting of the American Society of Engineering Contractors, William A. Jordan recently gave a description of the machine and its *modus operandi,* from which the following is abstracted:

The cement gun was originally conceived by C. F. Akeley, a taxidermist of Chicago. He desired to build the forms over which the skins of elephants and hippopotami might be stretched.

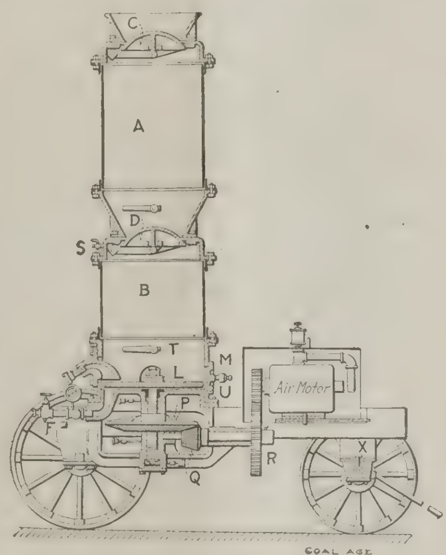
Mr. Akeley was also a member of the Field Museum Committee, and in that capacity sought to remodel and make permanent, one of the old World's Fair buildings in Jackson Park, Chicago, which had been presented to the Field Museum Association. An appropriation of modest proportions had been made for that purpose, and Mr. Akeley conceived the brilliant idea of remodelling the cement gun for that purpose.

Manner of Operation

The gun consists essentially of a hopper *A* into which the dry mixed materials to be used are introduced, through a valve *C*. This valve is closed and compressed air is admitted. Then the valve *D* is opened, and the material drops into the cylinder *B*. The use of the second cylinder is simply for the purpose of permitting continuous action. An air motor shown in the front of the wagon drives a feed-wheel *L* through the intermediate gears *R, Q* and *P*. Through the pipe *F* air is admitted which blowing through the feed-wheel at a pressure of 35 lb. per sq.in. carries the mixture through a flexible rubber hose which may be as long as 200 ft. The exit from the machine is by way of the goose-neck over the axle of the rear wagon-wheels. The mixed materials are perfectly dry and not wetted until they reach the nozzle held in the hand of the operator. A separate hose carries water to the nozzle at a pressure somewhat greater than that which propels the mixture. The water in the form of a fine spray mixes with the cement so that it issues from the gun ready for deposition and traveling at a speed of 300 ft. per sec.

Greater Strength and Adherence, Less Permeability and Porosity

The velocity at which the mixture is propelled serves several purposes. It is sufficiently great that all unnecessary water is driven out. The pressure assures that the concrete will be deposited compactly and hence, with the minimum of porosity. It is not remarkable then that its permeability varies from three-quarters to one-eighth that of hand-made concrete and that the latter will absorb from 1.4 to 5.3 times as much water.



The Cement Gun for Concreting

Any sand which is not coated with cement rolls off the surface and hence does not remain to weaken the aggregate, and this fact together with the greater density explains why the cement gun gives a coating of cement concrete from 1.2 to 3.6 times as strong in tension as hand-made mixtures of the same constituents. In compression the ratio of strength of gun-mixed to hand-mixed mortar vary from 1.2 to 8.2. The gun-work is relatively more successful in depositing the less rich mixtures of concrete. The voids in gun-made concrete are volumetrically 0.52 to 0.75 of those in the hand plastered material; the adhesive strength is from 1.01 to 1.42 times as great. So that the use of the cement gun is not only a cheap and quick way of coating surfaces, but also assures a coat of unusual strength in proportion to the cement used.

It may be added that the cement gun is manufactured by the General Cement Products Company of 30 Church St., New York City. In the cement work of the Woolworth Building as much as 417 cu.ft. have been deposited with a double nozzle gun in an 8-hour day despite some delays in moving the machine about the building.

Men Versus "Melons"

The president of the Plymouth Coal Co., John Haddock, has addressed a letter to the anthracite operators, of which the following is an abstract:

We believe and contend that a just and reasonable reduction of existing transportation rates for anthracite would enable the coal companies controlled by railroads to increase the wages paid to their employees without advancing the prices on prepared sizes. Nor would the wage increase work any hardship on the independent operators, if a corresponding advance were made in the unduly small proportion of the selling price now ascribed to them.

The existing rates of transportation are notoriously exorbitant. These rates are so excessive that the Reading mining operations, with a large annual production, with a great variety of anthracite, with an advantageous and profitable market, both local and coastwise, with operations which are managed with conspicuous skill and ability, and we believe with absolute honesty, showed during the period of six months a mining profit of 3c. a ton! Surely the patient mining Peter might ask and demand that the opulent transportation Paul give him a square deal. Poor Peter has spent many years of his life raising "melons" for Paul, and now in his later days he and his neighbors would like for the future to receive as adequate compensation a small slice of the luscious "melons," which are a result of his enterprise and industry.

How Bookkeeping Makes Profits

By the excessive transportation charges mentioned, practically the entire earnings of a subsidiary company have been con-

fiscated, the unjustifiable charges of the railroad for carriage of the coal being regarded as a primary and paramount obligation. But this method of bookkeeping might well be looked upon as a device of no public interest or concern, did it not have a far-reaching influence on the independent operator. Unfortunately for him, the arbitrary ratio assumed to exist between producing and shipping costs is made to apply to his coal, and it is therefore pertinent for him to consider the justice of transportation rates.

On this very point we have a recent authoritative opinion of the Interstate Commerce Commission. It reads as follows:

It requires no extended argument to sustain the proposition that the maintenance of an unreasonably high rate operates to the advantage of the Lehigh Valley R.R. Co. as a dealer in coal. The record shows that the only line of demarcation between the Lehigh Valley R.R. Co. and the Lehigh Valley Coal Co. is one of bookkeeping. Assuming for the purposes of illustration that the cost of mining anthracite coal is $2 per ton and the cost of carrying it to tidewater is $1 per ton, it follows that the cost of coal at tidewater would be $3 per ton; and if the published rate were $1 the independent operator and the railroad coal company would be on a fair competitive basis, so far as the cost of mining and transportation are concerned. But as between the railroad company and its coal company, it matters not whether the profit comes from mining or transporting the coal.

So, therefore, if, instead of the $1 rate above mentioned the railroad company were to establish a rate of $1.50 per ton, the railroad and its coal company could still sell at tidewater for $3 per ton, standing a deficit of 50c. per ton in the mining price and taking an equal profit in the transportation price. But the independent operator cannot recoup himself in this manner, and the best price that he could make at tidewater would necessarily be the mining price of $2, plus the carrying charge of $1.50, or $3.50; and he would enter the market at a disadvantage of 50c. per ton as compared with the railroad and its coal company.

It is obvious that such an advantage would enable the railroad company and its alter ego, the coal company, to monopolize the field of production and the selling market. Whatever the means employed, it is a fact that the railroad coal company has monopolized the coal field served by it. In 1901, 47 per cent. of the defendant's coal tonnage to Perth Amboy was controlled by it and 53 per cent. by independent operators; while in 1908 the defendant controlled 95 per cent. of the anthracite tonnage over defendant's line to Perth Amboy and the independent operators 5 per cent.

The Life of the Hard Coal Industry

The exhaustion of the anthracite coal supply was offered by the Lehigh Valley R.R. Co. to justify maintenance of the then existing transportation rates to tidewater. On this point, the commission says:

As to the kindred subject, namely, the exhaustion of anthracite coal supply, counsel in their brief thus state the result of the testimony of W. F. Dodge, an expert mining engineer, introduced as a witness on behalf of the defendant:

"The total future shipments from the Wyoming Division, starting with the year 1909, will amount to 91,230,000 tons. The lives of the various collieries will vary from 5 to 50 years. The annual output is estimated for the first five years to be 19,395,000 tons, and will diminish gradually until from the 25th to the 30th year, the annual output is estimated at only 7,055,000 tons, dwindling down in the period between the 45th and 50th years to 500,000 tons per annum. At the end of 25 years, according to the testimony of Mr. Dodge, the output of the Wyoming region will be less than half what it is now, and at the end of 50 years will cease altogether.

On the other hand, the following more optimistic view of the situation appears from the report of the Anthracite Coal Strike Commission, rendered to the President of the United States, Mar. 18, 1903, viz.:

What is of some importance, however, in connection with the discussion of the past production is a consideration of what is to be expected in the future in the way of production and the probable duration of the anthracite coal supply. The original deposits of the anthracite coal field have been ascertained with a reasonable degree of accuracy.

According to the estimate of the Pennsylvania geological survey, the amount of workable anthracite coal originally in the ground was 19,500,000,000 tons. The production to the close of 1901, as previously stated, amounted to 1,350,000,000 tons, which would indicate that there remained still available a total of 18,150,000,000 tons. Unfortunately, however, for every ton of coal mined and marketed 1½ tons, approximately, are either wasted or left in the ground as pillars for the protection of the workings, so that the actual yield of the beds is only about 40 per cent. of the contents. Upon this basis the exhaustion to date has amounted to 3,375,000,000 tons. Deducting this from the original deposits, the amount of anthracite remaining in the ground at the close of 1901 is found to be, approximately, 16,125,000,000. Upon the basis of 40 per cent. recovery, this would yield 6,450,000,000 long tons. The total production in 1901 was 60,242,560 long tons. If this rate of production were to continue steadily, the field would become exhausted in just about 100 years.

Mr. Wm. Griffith, in a series of articles contributed to the "Bond Record" in 1896, considers that the estimates upon which the foregoing computations have been made were too liberal. His estimate of the amount of minable coal remaining at the close of 1895 was 5,073,786,750 tons.

In the six years from 1896 to 1901, inclusive, the production has been, approximately, 308,570,000 tons, which would leave still available for mining 4,765,216,750 tons. This supply, at the rate of production of 1901, would last a little less than 80 years. If we can assume the annual production will have reached its maximum limit at between 60,000,000 and 75,000,000 tons, and that the production will then fall off as gradually as it increased, we may expect anthracite mining to continue for a period of from 200 to 250 years.—(Report of Anthracite Coal Commission.)

Defendant claims the right, to earn enough out of its coal rates to provide for a return of the principal of the investment in that part of the railroad company devoted to the carriage of coal, when and as this principal becomes reduced and extinguished by exhaustion of the coal. We have noted the estimate of defendant's witnesses to the effect that shipments of anthracite coal over the railroad will practically cease in 50 years, and we have quoted the opinion expressed on the same subject by the Anthracite Coal Strike Commission to the effect that production may last for 250 years. Probably the truth lies somewhere between the two extremes. During the years 1903 and 1910, the Lehigh Valley R.R. Co., under the rates in controversy, succeeded in accumulating an unappropriated surplus of $27,219,780. If the company could accumulate this sum for every eight-year period during the next 30 or 40 years, it would have a surplus in the neighborhood of $125,000,000. It seems, therefore, that the present rates are more than required to meet defendant's conception of what constitutes an annual income sufficient to provide for the return of the capital when that part of the railroad devoted to the carriage of anthracite coal loses its earning capacity through the exhaustion of that commodity.

Tidewater Freight Rates

As to the *cost* of carrying coal to tidewater, in this same opinion, reference is made to the testimony of the officers of Coxe Bros. & Co. and the Delaware, Susquehanna & Schuylkill R.R.—the "Coxe" road.

Prior to the sale of the interests of Coxe Bros. & Co. to the Lehigh Valley R.R. Co., the former owned and operated the Delaware, Susquehanna & Schuylkill, a road about 28 miles in length, which reached their different collieries and connected with the Lehigh Valley R.R. They had trackage contracts with the "Valley" covering the delivery of coal to tidewater.

The testimony of Mr. Pennington, superintendent of motive power, showed that the cost of moving coal to Perth Amboy, in cars of 100,000 lb. capacity, from the Coxe collieries, was 62.41c. per ton, which figure includes not only the return of empty cars to the mines, but also the profit of the Lehigh Valley R.R. Co. on its trackage charge and the profit in shipping of 12c. a ton at Perth Amboy.

Profitable Losses

Certainly, this *cost* of 62c., as related to the *charge* of $1.55, the tariff on prepared sizes of anthracite, might and does suggest a large and fertile "melon" patch. In the efforts to combat this testimony, the Lehigh Valley R.R. Co. tried to show that the average cost of carrying anthracite from the Wyoming region to Perth Amboy was $1.49. An exhibit filed by this company shows that its average receipts per gross ton of anthracite at Perth Amboy for the ten years ending June 30, 1908, were $1.46. Its business, under that testimony, during that period would show a loss of 3c. a ton, yet at the close of its fiscal year in 1908 the "Valley" had a surplus available for distribution of $20,722,871. After making certain deductions for dividends, improvements, sinking fund, etc., there was left an unappropriated balance of $16,516,904. At the close of its fiscal year in 1910, this unappropriated balance amounted to $27,219,780.

"Alice in Wonderland" might suggest that if the loss in carrying anthracite had been 6c. a ton instead of 3c., the "Valley" might have increased, if not doubled its surplus!

Storage Battery Electric Locomotives for Tunnel Haulage

Industrial storage-battery electric locomotives, designed for carrying the load on the locomotive itself, have been on the market some few years, but the pioneer locomotives of the storage-battery type, which are built for hauling trailing loads in tunnel work, have only recently been put into service. They are now being used in the New York aqueduct, which is being constructed for conveying the Catskill water supply into the city. Locomotives impelled by storage batteries, find application at present specifically for short-distance hauls at low speds, where it would not be possible or feasible to install the trolley system, as, for instance, over industrial tracks in and around factory buildings, or in places where continual changing of the trolley could not be avoided.

The section of the aqueduct tunnel in which these locomotives operate is about 11 ft. in diameter, concrete lined, and is being driven through solid rock from 250 to 300 ft. below the street level. A series of six shafts has been sunk, each approximately a mile apart, for expeditious operation, and the excavated material is transported to the mouths of the shafts on cars drawn by the locomotives, whence it is hoisted to the surface. Thus each locomotive has a maximum load haul of a half a mile per trip.

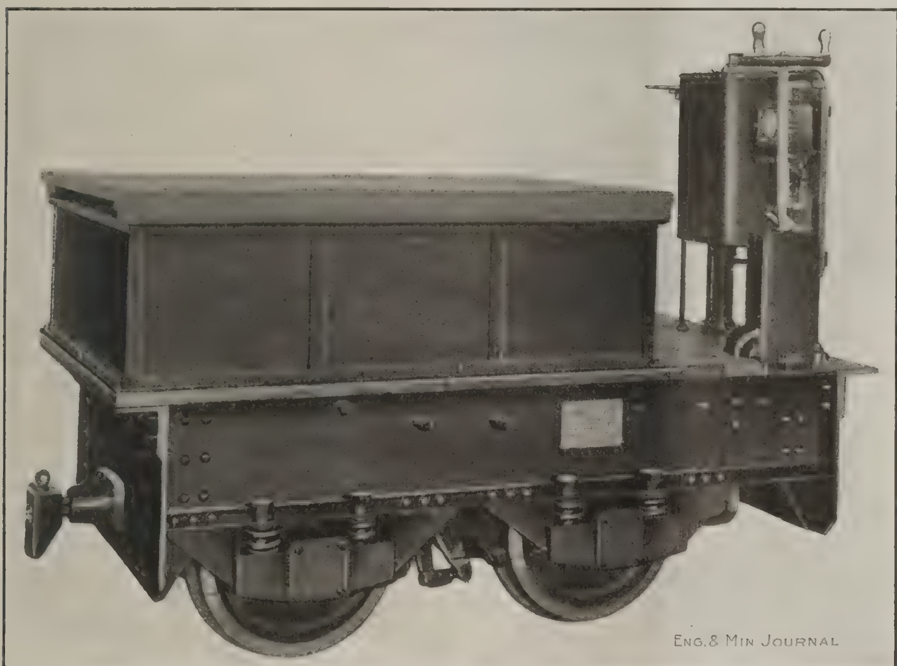
Smith, Hauser, Locher & Co., who are executing this contract for the city, recently placed in operation six storage battery electric haulage locomotives, manufactured by the General Electric Co., and have just ordered six additional locomotives. Trolley locomotives were out of the question because the tunnel headings would not permit their entrance. The operation of the locomotives employed has proved efficient and economical, and has permitted laying the tracks without filling, which hauling by mules would have required.

Locomotive Construction and Equipment

The locomotives in use are illustrated in Fig. 1 and conform to the following specifications:

Type of motor (single motor)	G.E.-1022
Diameter wheels	22 in.
Wheel base	36 in.
Total weight	7500 lb.
Length overall	7 ft. 10 in.
Height over batteries	4 ft.
Track gage	30 in.
Speed at rated T. E.	5 m. p. hr.

The batteries are of the 44-cell, 21-plate type and have a 45-amp. six-hour discharge capacity. The locomotives are equipped with an ampere-hour meter, headlight and gong.



Storage-battery Electric Locomotive

Latest modern practice has been followed in the mechanical design. The frame consists of two steel channel sides and steel-plate ends carefully fitted at the joints and held rigidly together with bolts and steel angles. A coupler suitable to the type of cars employed is attached at the rear end. Cast-steel pedestal jaws, which carry the journal boxes, are bolted to the lower web of the channel-side frames.

Automobile Type Motor

The motor used is of the automobile type, designed especially to operate from batteries, and has characteristics that effect the maximum possible economy in the use of battery current. It has high efficiency, large overload capacity and practically sparkless commutation. The motor is compactly designed, yet readily accessible for inspection and repair. It is dust and moisture proof, and is mounted in a cast-steel suspension cradle, one side of which is supported on bearings on the axle, while the other side is spring-suspended from the locomotive frame, in accordance with standard locomotive practice.

The motor drives the rear axle through double-reduction gearing, and an intermediate shaft, supported in the bearing housing, which is cast integral with the suspension cradle, carries the intermediate gearing. As slow-speed service is ordinarily required of a storage-battery locomotive, the use of double-reduction gearing permits such speeds without undue losses in the rheostat, and, because of the large gear reduction from the armature shaft to the wheel tread, high tractive efforts are obtained at comparatively small current inputs to the motor.

Combating Miners' Diseases

The following is an advance extract from the report of the director of the Bureau of Mines, for the fiscal year ending June 30, 1911:

"An arrangement has been made with the Public Health and Marine-Hospital Service by which one or more surgeons connected with that service will carry on jointly for that service and for the Bureau of Mines investigations looking to the improvement of mine conditions. These inquiries and investigations have already shown the prevalence of tuberculosis and hookworm as miners' diseases in a number of different localities in the United States. It is important that this work should be extended more rapidly, because of the fact that the health conditions, as well as the risk of accidents, may be influenced by conditions susceptible of easy improvement. Furthermore, the large and continuous influx of foreigners into the mining regions of the United States will bring to an increasing extent the hookworm and other diseases that abound in mines in parts of certain European countries.

"Various questions that concern the health of workers in mines, quarries and metallurgical plants cannot be answered finally without investigations and inquiries that are national in scope. Among such questions are the most efficient methods of preventing the diseases peculiar to certain industries, the most effective sanitary precautions to be observed in and about coal mines and metal mines, and the relative healthfulness of occupations pertaining to mining and metallurgical industries. The investigations and inquiries that are essential to the gathering of reliable information on these questions can be undertaken by the Bureau of Mines, in connection with its collection of accident statistics, in a prompt and efficient manner and at minimum expense."

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

All of the recent advances in coal-mining practice haven't been effected by time-worn Methuselahs with gray beards, false teeth and furrowed brows. A whole raft of sane ideas, new theories and improved methods have originated in the fertile minds of the "second generation."

Time was when a man had to lose his hair, contract rheumatism and be granddaddy to half a dozen humans before he could hope for recognition as a competent and practical mine engineer, but we have come to realize that ability to sit tight in a canoe and drift with the current is not as great a virtue as being able to paddle straight to the desired landing. Results accomplished merit greater approbation than time consumed.

No young man engaged in coal mining today has traveled faster or been of greater benefit to the industry than Harry M. Warren, electrical engineer for the Delaware, Lackawanna & Western company. He handles electricity like a Southern darky does a watermelon—goes to the center first, and then eats his way out. Some day, not so far distant, the D. L. & W. won't need anybody in the coal department but Harry, for he will be able to throw on a switch, which will be all that is necessary to mine, prepare and ship his company's coal to tidewater.

Mr. Warren was born in Worcester, Mass., in 1875. Graduated from the Worcester Polytechnic Institute in 1896, taking a P. G. in '97. Following his graduation from college, "H. M." started in contracting work at Montclair, N. J., changing from this work a few months later to the testing department of the General Electric Co., Schenectady, N. Y. On leaving the General Electric, in 1900, Mr. Warren was made electrical engineer for the D. L. & W. Co., and he and they have stuck together like a porous plaster on a lame back.

When Mr. Warren took up coal mining 12 years ago, there wasn't much electricity used in or about the collieries. Some of the companies employed main haulage locomotives, but there were no gathering motors in use. A number of mines had electric hoists on slopes and planes underground, but no electric hoists at shafts. Electric plunger pumps were about the only style used, and there was no electric power in the breakers. Practically all the current was "direct," and power was generated by engine-driven generators at each individual colliery.

One of the earliest and most important developments of the past decade was the gathering locomotive. Following close on this improvement came centrifugal pumps. Concerning the latter, Mr. Warren is an ardent advocate of this style of pump in all cases where large bodies of water have to be handled, and this recommendation he makes regardless of head. Bronze pumps are his choice when bad water is encountered, and it is his idea that the best way to use centrifugal pumps, on a slope, for instance, is to operate them in series, placing the pumps at intervals, so that each will operate on a 100-ft. head. He says that when a centrifugal pump falls down in the handling of a large quantity of water, its failure is due, in nearly every case, to the machine being of improper design. The advantages of centrifugal pumps are their ease of handling, and the fact that they can be placed in a cramped space.

Harry M. Warren

Both direct and alternating current are used to drive pumps, but Mr. Warren recommends the latter for station pumps, because, (1) it permits the use of high voltage; (2) gives advantages of an induction motor; (3) eliminates trouble from variation in speed. He suggests the use of direct current for movable pumps.

Mr. Warren says that his company at present is operating a large number of hoists driven by alternating-current motors. The present maximum capacity of these hoists is 200 hp., but he is firm in the belief that before very long, similar equipments of 600 hp. will be installed. As to the advantages of alternating-current over direct-current hoists, he says that the chief advantage is in the transmission of power, especially as to the size and cost of wire.

One of the most interesting of Mr. Warren's views is in reference to the use of electric hoists for shafts. He believes that it does not pay to operate a shaft hoisting equipment by electricity, when the shaft is located at a colliery where a boiler plant is necessary for other purposes. This is particularly true if the exhaust steam can be used to advantage in a low-pressure turbine, or otherwise be utilized. Although a steam hoist is less efficient than an electrically operated plant would be, the initial cost of a steam operated installation is so much less than for an electrical hoisting-station equipment that the initial saving is sufficient to overbalance any reduction in operation charges that results from the use of an electric hoist.

In this connection, it is necessary to remember that at all anthracite collieries, where the coal has to travel through a breaker, a boiler plant is required to supply heat in the breaker, and to keep the water that is used in preparation of the coal from freezing. All the saving from an electrical equipment results from economy in the use of coal, and, therefore, the higher the price of coal, the more favorable is the proposition to the use of electricity. "H. M." is ready to concede that the electric hoist permits better control and occupies less space.

In breakers, he advocates the use of motors because, (1) they eliminate countershafts, pulleys, belts and ropes; (2) afford greater flexibility, in that each individual equipment can be located with reference to any other part, insofar as the drive is concerned.

In conclusion, "Harry M." believes that all power used in a mine, where practicable, should be electric power. He suggests, however, that the poor steam economy at most collieries is due principally to the losses from radiation and drips when the equipment is not in operation. The ability to burn small sizes of coal at a high rate of combustion has recently been given much attention by his department, with the result that today he finds it possible to burn barley coal and develop at least 60 per cent. over-rating, while a few years ago it was difficult to operate normal rating with the same grade of fuel.

COAL AGE

The Leaders and the Led

Rapid changes have taken place in the anthracite strike since the members of the joint committee appointed by the United Mine Workers refused to accept the settlement of the subcommittee. As that smaller body was not invested by either party with plenary powers to effect a settlement, it is easy to understand why the larger body felt justified in refusing to accept it.

Yet it must be remembered that the members of the subcommittee while meeting behind closed doors had plenty of opportunity to confer with their confrères, and doubtless did so during every recess. The events showed that the body of mine workers refused to stand back of their representatives and abide by their decisions. Nevertheless, it must be admitted that the remarks of George F. Baer were undiplomatic, and it was not well advised to hold the joint committee to any other action than that to which they stood committed by the words of their reference.

On the other hand, the miners will have to learn that they must give plenipotentiary powers to their executive officers. No success can attend them if all their *pourparlers* are mere waste of time, and some irritability in the opposing parties with whom they thus treat so irresponsibly is but natural under the circumstances. We do not think that the operators have acted wisely in attempting to load even a small quantity of coal while the opportunity to settle the strike is still so favorable. Such attempts can only irritate the men.

The English-speaking miners have shown a desire for peaceable methods. The rioting up to date has been confined almost entirely to the Southern fields, where foreign labor predominates. The Northern district, which is inhabited principally by Americans, has preserved the peace, except in one or two localities. The English-speaking miners have shown a politic disposition and view with no little regret that the foreign element is pursuing un-American methods of settling the dispute, and injuring the instruments by which their livelihood is secured.

We think that the operators cannot accede further demands without weakening their position in the market, and as far as a recognition of the union is concerned, the miners have been granted more concessions than seemed likely when the strike started. What recognition the union has received was conceded because the operators believed that the miners' organization would be a reliable body with which to conclude an agreement.

If the United Mine Workers Union is nothing, can do nothing, and stands powerless to meet socialistic violence and the machinations of foreigners, then there will be no value in recognition. The Mine Workers are proving that the early contention of the anthracite operators was true, and that the elements opposed to the union and opposed to law and order will not be bound by anything the union will agree to do.

It is time for the American element in the union to declare that their federation stands for order, and will approve what has seemed acceptable to its representatives.

Consumption

We always supposed the coal miner was healthy, and statistics favoring that belief only confirmed us in that view. But we see that the Bureau of Mines and Marine Hospital Service would not have it so and have combined to decimate the ranks of the miner with phthisis and hookworm. If the *coal* miner is to be thus menaced, we wish to protest. The U. S. Government every ten years gives him a clean bill of health, and Samuel G. Dixon, the Commissioner of Health of the State of Pennsylvania, showed in his report of 1908 that the miner was but little subject to consumption.

We quote, however, as a corrective of all false notions, the words which the director of the Bureau of Mines hopes to incorporate in his report to the President, and which we include today in our

pages: "Inquiries and investigations have already shown the prevalence of tuberculosis and hookworm as miners' diseases in a number of different localities in the United States."

The report of the Health Department of Pennsylvania, to which reference has been made, shows the following figures for tuberculosis, giving the percentage of deaths from that disease to those from all causes for all occupied males, and for miners and quarrymen.

Ages	All Occupied Males Percentage	Miners and Quarrymen Percentage
25-34	30.9	5.3
35-44	24.3	11.8
45-54	14.4	11.6
55-64	7.6	12.8

In the first period of 10 years, consumption is particularly deadly among plumbers and gas fitters, 42.9 per cent. dying of tuberculosis. In the second decennial period the compositors, printers and pressmen show the largest death percentage from that disease; to wit, 49.2 per cent. In the next ten years the mill and factory (textile) workers have the highest figure, 17.5 per cent., and in the final period domestic servants have the greatest proportion of deaths from this malady, 13.0 per cent.

But it may be objected that the miner probably has a high death rate from all causes, especially from that of physical violence. This would account for the low percentage of deaths from consumption compared with those from all causes. But neither the statement nor its deduction is sustained so far as the somewhat restricted investigations of the Census Bureau in 1900 extend. The miner lives a fair span of life. To quote the exact words of the report on Vital Statistics, published in 1902 by that bureau: "The table" of miners' mortality "shows that the death rate of miners and quarrymen was much less than the average rate in this class." Totalling the government table, we find that while only 882.1 miners died in every 100,000 from all causes, 1298.5 occupied males in the same number succumbed to all manner of diseases and accidents. The mining and the quarrying class has, therefore, a distinctly lower death rate as far as the Census Bureau's figures extend.

Moreover, according to the same Vital Statistics, only 120.9 miners died in every 100,000 from tuberculosis, whereas of all occupied males 236.7 individuals died per 100,000 from that disease.

Such tuberculosis as is to be found among miners is largely confined to those men who work in metal mines. An accurate count of the coal diggers would doubtless show a comparative immunity among men working at the coal face.

The Mine Surveyor

State or governmental laws regulating the practice of mine surveying is one of the many serious problems confronting the coal industry today. Great Britain has finally adopted a definite policy in this respect by prescribing certain qualifications for mine surveyors, but there appears to have been such active opposition to the passage of the act that the ultimate result has been a relatively weak and ineffective compromise. Thus a certificate of competency may be obtained either from the Board of Mining Examinations, an approved educational institution, or will be issued on application to all holders of a first-class manager's certificate.

We seriously question the assumption that the college man, devoid of practical experience, is competent to assume responsible charge of extensive surveys. Nor do we believe that the qualifications of the surveyor should be determined entirely by mental examinations in mathematics, surveying, etc., since it is not at all improbable that a well posted draftsman, who has never been in a mine, could successfully stand such an examination.

Those familiar with colliery-engineering departments appreciate the value of a conscientious and thoroughly reliable transitman, and know that such men are found only among the experienced and well seasoned members of the profession. Any of the older engineers, looking back on the time they served as surveyor, can doubtless recall new shortcuts, checks and possible causes of inaccuracies which they continually were discovering.

Should state or government intervention along this line be attempted, it is to be hoped that the practical side will not be ignored entirely, as is too often the case. Errors in mine surveying frequently result, not only in heavy monetary losses, but in numerous fatalities, and if we are to have laws, let them be effective. "Running" a transit might be likened to running a locomotive, in that no experienced engineer would any more consider engaging an instrumentman on his mental attainments alone, than a railroad superintendent would think of hiring a locomotive engineer on like qualifications.

Present Day Waste

The conservationists have discussed the good of posterity so much that conservation has now a bitter smack of priggishness, like several other well meaning words—institutional work, welfare, altruism, uplift, benevolence and the rest of the drab sisterhood. But there is nothing benevolent about most forms of conservation, though the least hopeful and most remote forms have the loudest and most insistent "barkers."

Unfortunately, the figures for the days worked in mines of the United States in 1909 are not yet published, but in the five years preceding the year 1911, excluding the year aforesaid, the anthracite mines in Pennsylvania lost 507 days, excluding Sundays. The bituminous mines of the United States lost in the same period 498 days. This loss of productivity must have resulted in raising all the costs of producing coal.

Of course, miners are often absent from mines during the days when coal is being dumped, but, on the other hand, not a few work when the mines are officially declared idle, so that perhaps the productivity of a mine is normally to be gaged by the number of operating days.

The idleness increases the cost of coal, makes capital meanwhile unproductive, involves losses for upkeep and pumping, and results in the loss of tonnage.

In fact, it is possible that if by a combination of operators, this lost time could be reduced, there might be a reduction in the cost of coal, which would gratify consumers and make conditions better for owners and miners alike. The public must in the long run pay for the time during which the miner folds his arms or saunters casually downtown, or to the commissary.

The British Royal Commission on Mines has recommended the establishment of a lamp-testing station for the investigation of the velocity of explosive currents which different types of lamps can withstand, together with their illuminating power and sensitiveness in testing for mine gas. An excellent suggestion for our Bureau of Mines.

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Steel Mine Ties

Steel mine ties have been used to advantage in some districts. The accompanying Fig. 1 shows the latest, best and cheapest form of steel tie made. It is but ½ in. thick as compared to the 4 in. or more of a wooden tie, and this means a corresponding saving in the height to which every pound of coal must be lifted to be loaded into a mine car. The bolts used in the tie are the same as those in the rail-splice bars and no sledges, gages, spikes or spike pullers are needed for either laying or taking up ties. The only tool required is the wrench that is used for the rail-splice bolts.

in. bolts so that the track will be flexible and easily shifted sideways to enable it to be laid on considerable of a curve and yet not spring back but stay where it is put. The amount of flexibility depends on the length of the rails and the shorter they are the greater is the flexibility.

Ties of this general form have been known for years, but the particular improvements that this tie possesses and which make it superior to other types, are the use of loose-riveted clips that cannot get lost, and of washers to make thickness enough so that the same track bolts can be used as for the splice-bars. A further advantage is that the clip is easier to make because it is straight. The bolt

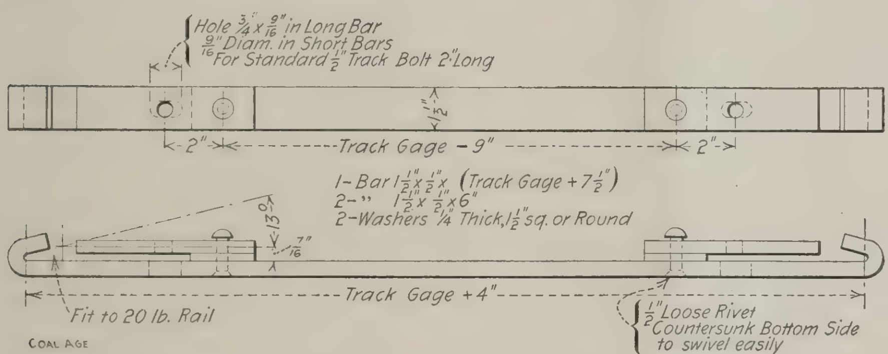

FIG. 1. MINE HAULAGE, STEEL TRACK TIE FOR MINE CARS

When these ties are used approaching the working face, short-length rails can be used with them, cut the same length as the depth of undercut made in the coal, in any particular mine. As the rail rests right on the floor but one tie, per rail length of 6 ft., or less is required. Since the gage is rigidly correct there is less trouble experienced from cars running off the track than when wooden ties are used; and there is less obstruction to travel for a mule, horse or man and less chance of injury to them through getting a foot caught or stumbling. The number of times that a wooden tie can be laid or taken up is limited, but there is no limit to the number of times this steel tie can be used. If bent it is easily straightened.

Each rail should have a pair of splice-bars loosely riveted on one end, so as to insure having splices where and when they are wanted, and to save labor in laying track. The splice-bars will have two of their holes already used, and putting down a length of track simply means putting in two bolts in each tie and two in the splices. The bolt holes in the rails should be ¾ in. for ½-

hole in the tie is oblong to suit the diamond-shaped head end of a track bolt so that it cannot turn while the nut is being tightened or loosened, particularly the latter; because after a tie has been down a while the nut rusts the same as it does in the rail splice. The same track is good for outside use, for slate dumps and other temporary tracks. The first cost, per tie, is twice that of wood, but since not more than half as many are required, per foot of track, the total cost is no greater, while the steel ties are cheaper to lay and take up and are longer lived than wooden ties.

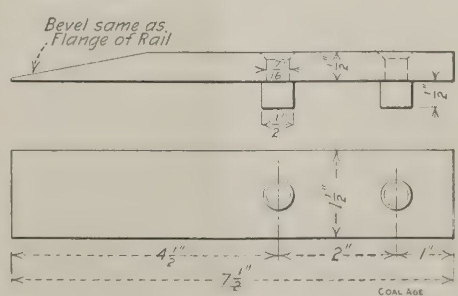

FIG. 2. STEEL MANDREL FOR SHAPING THE BENT ENDS OF STEEL TRACK TIES

In making these ties in an ordinary blacksmith shop, the holes are first punched or drilled by gage, then the bar to be bent is heated and a tool like that shown in the accompanying Fig. 2, is placed on it for a form, over which the bent end is quickly shaped by a few blows of the hammer. All parts are thus made to the same gage. The bottom head of the rivet is countersunk, as shown in Fig. 1, because it is easier to beat down such a head than it is to use a rivet set.

Ellsworth, Penn. F. D. BUFFUM.

Watering vs. Sprinkling

Referring to coal dust in mines, the Royal Commission, appointed some time since to investigate coal-dust explosions in mines, based their conclusions, if I am not mistaken, on the following points:

First. The best way to deal with coal dust is to see that all dusty entries and rooms are kept "watered," not "sprinkled." There is a difference in the meaning of these two words, watered and sprinkled. There is, I think, too much sprinkling and not enough watering done in our mines. In mines where the roads are dusty, the fireboss should be empowered to order that all roads be watered—watered, not sprinkled. In some mines, this watering is done with a watering car, which is, in my opinion, the best method to employ. In other mines, sprinkling is done by means of pipes laid on the roads and airways.

I will confess that the use of the watering car may often prove a disadvantage, especially in mines where there is a large output of coal. Nevertheless, we must consider the lives of the bread-winners and the wives and children dependent upon them. The watering car is often considered an unnecessary item of expense, as it requires the employment of one or two extra drivers and as many mules. If, however, this method would save the lives of even ten men, in one year, in the United States, I am sure that would counter-balance the extra expense, with interest added.

It has given me great pleasure to read the comments of James Ashworth, in COAL AGE, Apr. 20, p. 917. Mr. Ashworth gives his veiws on the watering of dusty mines, which I know will be greatly appreciated by many readers. I hope to see further discussion of this important question.

Terre Haute, Ind. FIREBOSS.

Reducing Ventilation When Firing

I have followed with much interest the discussion of this subject in COAL AGE, and must say that the contributions have furnished many valuable hints. Stress has been laid upon the dangers attending a strong draft, rapidly moving currents of air, and of fine dust carried in suspension in the mine air. There is, no doubt, some wisdom in reducing the ventilation when firing shots in a mine. Perhaps, however, the most interesting phase of the subject has not yet been touched. No doubt, some readers can recall having heard old superintendents say there were never any serious dust explosions in their particular sections of the country before mining laws made larger fans and greater volumes of fresh air compulsory. The popular demand was for fresh air for the miner, and that is the cry today in open light mines, where gas is never found.

But there is another side to this important question. The close analytical study of mine air is now beginning to change many long standing ideas concerning ventilation. There was a time when physicians tried to diagnose a patient's disease by looking at his tongue and timing his pulse. Today, a sample of the blood or waste product is taken and examined under the microscope, or chemically analyzed before the patient's true condition can be known.

In like manner, we are beginning to learn what kind of mine air is necessary to maintain health, also the kind of air in which it is possible to start a dust explosion. The chemist has suggested that the best method for the prevention of dust explosions in mines is to reduce the oxygen content of the air to 20 per cent., and for the most dangerous mines to 19 per cent., with a little carbon dioxide present. Such air, it is stated, is now breathed by men working at the coal face, in most mines, which is given as the reason why dust explosions seldom, if ever, traverse the working face.

We are told that with an atmosphere containing less than 17½ per cent. oxygen (or 17½ per cent. with a little carbon dioxide, say ¾ of 1 per cent.), it is not only impossible to start a dust explosion, but also with this percentage of oxygen in the mine air, firedamp mixed in any proportion will not ignite when a flame is applied to the mixture. It is also further stated that with this depletion of oxygen in the air, a fire of wood or coal, in the roads, cannot be started.

Someone recently wrote Dr. Haldane, suggesting the feasibility of treating the intake air of a mine with furnace gases, and he replied, in relation to the depletion of the oxygen of the air by this means: "I can see no physiological difficulty in reducing the oxygen to 17½ per cent., provided you can eliminate the difficulties with carbon monoxide, also the lighting difficulty."

But in many mines, especially where carbon dioxide is given off by the coal, artificial treatment of the ingoing air will not be necessary to produce certain air conditions in the working places where shots are fired.

Perhaps this phase of the problem is worthy of extended discussion by readers. I will hazard the opinion that in the near future we shall regularly take samples of the mine air, and depend more upon the chemical analysis of such air when regulating ventilation than upon the anemometer. And all modern mines will be equipped with air-sampling and analyzing apparatus, as well as anemometers. Our ventilation laws will also be modified.

SAMUEL DEAN.

Delagua, Colo.

[A practically insurmountable difficulty in regard to any sampling and analyzing of the mine air is that which has always rendered useless such tests; namely, the conditions in the mine are constantly changing, and any such test can only have a local value, which will probably be of no avail by the time the results of the test are known.—EDITOR.]

The Pittsburg Rate Case

While I have no interests whatever in the Pittsburg rate case, I have been following this matter closely, and cannot see wherein any of the Pittsburg operators are benefited, as you seem to infer in your editorial on this subject in the Apr. 27 number. We are advised that the rate on coal to the lakes from the Fairmont and Kanawha fields has been reduced 10c., thus putting these rates on practically the same basis as heretofore. We do not have copies of the tariffs showing this reduction, but we were informed from reliable sources that such is the case.

In another place in the same issue, you state that the Pittsburg operators have increased their prices on coal to overcome the advance given the men. It has been true for the last several years that the Pittsburg operators increase their prices on coal, but they have never maintained these, and I venture the assertion that the prices on coal will be as low, if not lower, this year than last year.

There does not seem to be any question but that the increased development in the coal fields is more than the increased consumption, and, moreover, the railroad companies are in better position to move this commodity more quickly and they are furnishing a greater car supply than they have ever furnished before.

This letter may sound pessimistic, but it is not written with that idea. I believe that there should be an adjustment of the various freight rates, and your article with reference to the anthracite coal freighters bears this statement out. If the various companies and trade papers would follow this up it would surely help considerably.

S. A. CARSON,
General Manager.

So. Connellsville Coke Co.,
Uniontown, Penn.

[Our correspondent in stating that the rate from the Fairmont and Kanawha fields has been reduced 10c. has evidently misinterpreted our editorial or been misinformed. Quoting from the editorial: "As is well known, the Fairmont and Kanawha fields are the most important competitors in the Lake trade, and no revision in rates from these districts has been made." In the cases of the Baltimore & Ohio, the Chesapeake & Ohio and the Kanawha & Michigan lines, the decision was that the present rates from the Fairmont, Kanawha and New River fields of 96¾c., 97c. and $1.12 a ton respectively were fair and just, the proposed rates of $1, $1.06½ and $1.21¼ not being justified. While no increase in these rates was made, there was not, on the other hand, any reduction, as our correspondent seems to infer, although the fact that no increase was granted acts indirectly as a decrease.

With reference to Mr. Carson's assertion to the effect that the price on coal would be as low, if not lower this year than last year, and questioning our statement that the Pittsburg operators have increased their prices to overcome the advance given the miners, we believe in the former instance that such may quite probably be the case. We presume that he is referring to the statement in the first column on page 960, which says: "There is no demand but producers are naming prices on a basis of 7½c. higher than last year's regular or official basis." Further along in the same paragraph it says: "These prices constitute the quotable market at the moment, but whether they will hold is another matter. Last year's prices based on $1.15 were shaded during the major portion of the season." It will be noted here that we give these figures as the quotable market at the moment and question ourselves whether they will hold. And we further note that last year the quoted prices were shaded during most of the season. Our correspondent is thoroughly justified in his belief that the present circular prices will not be maintained throughout the season, as has been amply proved in previous years, but since these are the prices being quoted at the present time, they are obviously of value to the trade.—EDITOR.]

Inquiries of General Interest

All Questions Must be Accompanied by Name and Address—Not for Publication

Will a Carbide Lamp Burn in Carbon Dioxide?

Kindly answer the following questions in COAL AGE: Will a carbide lamp burn in carbon dioxide? What is the chemical formula for calcium carbide and the equation that expresses its reaction with water and shows the resulting gas that produces the light? Is it true that the chief mine inspector of Ohio will not permit carbide lights to be used in the mines in that state?

C. K. ROCKHOLD,
Night Foreman.

Sunnyside, Utah.

The question is often asked, "Will a carbide lamp burn in blackdamp?" and the answer is, "Yes." There is, however, a great difference between blackdamp and carbon dioxide. The former is a variable mixture of one or more extinctive gases and air. It therefore contains some available oxygen, which supports the flame of the lamp. On the contrary, carbon dioxide (CO_2) contains no free or available oxygen; and, for this reason, no flame dependent on oxygen for its combustion can burn in this gas.

It is often asserted and the idea has become quite prevalent that a carbide lamp will burn in an atmosphere of carbon dioxide; that it is not dependent for its combustion on oxygen or air; and this argument has been used, at times, to press the claims of this lamp for mining use. Both statements are wrong. The idea probably grew out of the fact that it is common for mining men to call blackdamp, carbon dioxide. But, as just explained, the two are widely different; and, while the carbide lamp will burn in blackdamp that will extinguish most other lights, it will not burn in pure carbon dioxide, because that gas contains no free oxygen.

The acetylene flame of the carbide lamp, like the hydrogen flame, is extremely tenacious. While a candle and other wick-fed flames are extinguished by about 14 per cent. of carbon dioxide added to the air (artificial atmosphere); or by from 3 to 4 per cent. of carbon dioxide, in a residual atmosphere, where the flame is inclosed in a confined space and allowed to burn till it goes out; the hydrogen flame is only extinguished, in an artificial atmosphere, when the latter contains practically 58 per cent. of carbon dioxide; and the acetylene flame is almost equally tenacious.

It is important, however, in this connection to state that, owing to this property of the acetylene flame, the carbide lamp fails to indicate the presence of blackdamp in the mine air, with sufficient promptness to avoid danger, since 18 per cent. of CO_2, in an artificial atmosphere*, may produce fatal results if breathed but a short time. The lamp is not a safe lamp to use in mine workings generating much blackdamp, any more than the electric lamp is safe in mines generating marsh gas.

The chemical formula for calcium carbide is CaC_2. The chemical equation expressing the reaction of this carbide with water is:

$$\underset{\text{Calcium carbide}}{CaC_2} + \underset{\text{Water}}{2\ H_2O} = \underset{\text{Calcium hydrate}}{Ca\ (OH)_2} + \underset{\text{Acetylene}}{C_2H_2}$$

The equation that expresses the combustion of the acetylene gas in oxygen is:

$$\underset{\text{Acetylene}}{2\ C_2H_2} + \underset{\text{Oxygen}}{5\ O_2} = \underset{\text{Carbon dioxide}}{4\ CO_2} + \underset{\text{Water vapor}}{2\ H_2O}$$

The Ohio mining law, as revised June 11, 1910, and again the following year, 1911, prohibits the use, in any coal mine in that state, of "any fish oil or other luminant whatever, other than those specifically provided for" in the section (974).

The chief mine inspector, June 5, 1911, issued a circular drawing attention to the new law and notifying all mine foremen in charge of mines, in the state, that they would be held responsible for the use of any illuminant, in their respective mines, other than oils of the standard required by law.

*The term artificial atmosphere as here used, means an atmosphere containing a normal percentage of oxygen, the CO_2 being added; in distinction to a residual atmosphere, which is the atmosphere resulting from the burning of a lamp, or some other form of combustion, by which the oxygen content has been depleted. Practically, all mine atmospheres containing blackdamp or other gases are artificial atmospheres, except the afterdamp of an explosion, which may b[e] residual.

Safety Lamps, Types and Construction, Relative Safety

Please explain the essential differences and the construction of the Davy, Clanny and Wolf lamps. Which of these is the safest lamp to use in a gassy mine; and in what does this safety consist?

STUDENT.

Altoona, Penn.

The Davy lamp has no glass but a full gauze chimney surrounding the flame, which permits a free circulation of air passing in and out of the lamp. While this free circulation of air renders the Davy more sensitive to gas than is the case with other lamps, the same fact makes it an unsafe lamp for general work or to place in the hands of the ordinary miner. The lamp, because of its sensitiveness, "flames" readily in gas. When this happens it requires much presence of mind and self-control to avoid making a sudden movement that may force the flame through the gauze and fire the gas outside of the lamp.

The Clanny lamp differs from the Davy in having a glass cylinder surrounding the flame and which forms the lower half of the chimney; the upper half being gauze the same as the Davy. This improves the light, which is not obstructed by the gauze mesh. The air enters the Clanny lamp through the lower portion of the gauze, above the glass, and must therefore descend to the flame. There are, thus, two conflicting air currents in the lamp, which gives all Clanny lamps a tendency to smoke. This lamp is not as sensitive to gas as the Davy lamp, but affords greater protection of the flame against strong air currents.

The Wolf lamp is an improved type of Clanny lamp, having a glass cylinder surmounted by a gauze chimney. It differs from the Clanny in the fact that the air enters this lamp through a gauze ring below the glass, which gives a better circulation in the lamp and improves the light. The Wolf lamp is particularly designed to burn naphtha, a highly volatile and explosive oil. The oil vessel of the lamp contains a specially prepared cotton that is used to absorb the oil and reduce the danger of explosion in the lamp. Owing to the ease with which the naphtha flame is extinguished, the Wolf lamp is supplied with a special igniter for relighting the lamp when accidentally extinguished.

No so called safety lamp is *safe* unless properly handled, and kept in good condition. Its safety depends on the isolation of the flame from the outside air, by means of a chimney of wire gauze, or glass and gauze combined. The cool wire forming the mesh of the gauze allows the free passage of the air and gas, but kills the flame by absorbing its heat whenever the flame approaches the wire. If the gauze becomes heated, or is imperfect or dirty, or the lamp is exposed to a strong air pressure, the flame may pass through the mesh of the gauze. In other words, under these conditions, the lamp may fail.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Sundry Examination Questions

(Answered by request)

Ventilation, to Find Area for Given Length of Airway, Quantity of Air and Water Gage

Ques.—What must be the sectional area of an airway 5000 ft. long, in order that it will pass 10,000 cu.ft. of air per min., under a water gage of 1.7 inches?

Ill. Exam.

Ans.—In order to solve this question it is necessary to know the shape of the cross-section of the airway, so as to be able to reduce the two unknown quantities (perimeter and area) to a single term (diameter or side).

The formula for unit pressure, in terms of the airway and quantity of air, is

$$p = \frac{kloq^2}{a^3}$$

In this case, the values are all given except the perimeter (o) and area (a); therefore,

$$\frac{a^3}{o} = \frac{0.00000002 \times 5000 \times 10{,}000^2}{5.2 \times 1.7} = 1131.22$$

For circular airway,

$$\frac{a^3}{o} = \frac{(\pi r^2)^3}{2\pi r} = \frac{\pi^2 r^5}{2} = 4.9348\, r^5$$

and

$$r = \sqrt[5]{\frac{1131.22}{4.9348}} = \sqrt[5]{229.23} = 2.96, \textit{ say } 3 \textit{ ft.}$$

The diameter of this airway, to meet the requirements in the question, must be practically 6 ft., and its area is then

$0.7854 \times 6^2 = 28.27$ sq.ft.

For square airway (side = d, area = d^2),

$$\frac{a^3}{o} = \frac{(d^2)^3}{4d} = \frac{d^5}{4}$$

Then

$$d = \sqrt[5]{4 \times 1131.22} = 5.384 \textit{ ft.}$$

$$\textit{Area} = 5.384^2 = 29 \textit{ sq.ft.}$$

For a rectangular airway (height = a, width = b), perimeter = $2(a + b)$; area = ab.

Assume $b = na$; then,

$$\textit{Perimeter} = 2(a + na) = 2a(n + 1)$$

$$\textit{Area} = a \times na = na^2$$

Then,

$$\frac{a^3}{o} = \frac{(na^2)^3}{2a(n+1)} = \frac{n^3}{2(n+1)}a^5$$

Suppose the width of the airway is double its height; then, $n = 2$; and

$$\frac{a^3}{o} = \frac{2^3}{2(2+1)}a^5 = \frac{4}{3}a^5$$

Finally,

$$a = \sqrt[5]{0.75 \times 1131.22} = 3.85 \textit{ ft.}$$

$$b = 2 \times 3.85 = 7.6 \textit{ ft.}$$

The airway, in this case, is 3.85×7.6 ft.; its area is $3.85 \times 7.6 = 29.26$ sq.ft.

It is thus seen that a circular airway requires the smallest area; the square airway the next; and the rectangular the largest, to pass a given quantity of air under a given pressure.

Ventilation—Comparing Two Airways

Ques.—Of two airways, one 7 ft. wide and 6 ft. high, the other 14 ft. wide and 3 ft. high, which will pass the greater quantity of air, other conditions being equal; and why?

Tenn. Exam.

Ans.—The areas of these airways are equal; $7 \times 6 = 42$ sq.ft., and $14 \times 3 = 42$ sq.ft. Assuming the airways have the same length, the one having the smaller perimeter will have likewise the smaller rubbing surface, and will pass the greater quantity of air, for the same pressure or power on the air.

The perimeter of the airways, in this case, are, respectively,

6x7-*ft. airway*, $2(6 + 7) = 26$ *sq.ft.*
3x14-*ft. airway*, $2(3 + 14) = 34$ *sq.ft.*

The 6x7-ft. airway will therefore pass more air, under the same pressure or power, than the 3x14-ft. airway. The ratios of the quantities are as follows:

Equal pressure,

$$\frac{q_1}{q_2} = \sqrt{\frac{34}{26}} = \sqrt{1.3077} = 1.14+$$

Equal power,

$$\frac{q_1}{q_2} = \sqrt[3]{\frac{34}{26}} = \sqrt[3]{1.3077} = 1.09+$$

That is to say, for each 10,000 cu.ft. of air in the 3x14-ft. airway, under equal pressure, the 6x7-ft. airway will pass 11,400 cu.ft.; or, under equal power, 10,900 cu.ft. of air.

Percentage of Gas, Height of Cap

Ques.—What is the formula for calculating the percentage of gas from the height of flame cap observed? What percentage of gas is indicated by a ¾-in. cap?

Ans.—When using the unbonneted Davy lamp, the percentage of gas is given by the formula

$$J = \sqrt[3]{36h}$$

Or, for a ¾-in. cap

$$J = \sqrt[3]{36 \times 0.75} = \sqrt[3]{27} = 3\%$$

When using a bonneted Davy

$$J = \sqrt[3]{70h}$$

Or, for a ¾-in. cap

$$J = \sqrt[3]{70 \times 0.75} = \sqrt[3]{52.5} = 3\tfrac{3}{4}\%$$

Horsepower in Ventilation

Ques.—(a) If 10 hp. is producing a circulation of 60,000 cu.ft. of air, in a mine, what is the water gage? (b) What quantity of air and what water gage will be produced in this mine, when the horsepower is increased to 25 hp.?

Ans.—(a) The water gage is

$$w.g. = \frac{10 \times 33{,}000}{5.2 \times 60{,}000} = 1.057 \textit{ in.}$$

(b) In any given mine or airway the quantity of air circulated is proportional to the cube root of the power producing the circulation. Or, in other words, the quantity ratio is equal to the cube root of the power ratio. Then since the water gage (or pressure) varies as the square of the quantity, the water-gage ratio is equal to the cube root of the square of the power ratio. Hence, for the quantity,

$$\frac{q}{60{,}000} = \sqrt[3]{\frac{25}{10}} = \sqrt[3]{2.5}$$

$$q = 60{,}000\sqrt[3]{2.5} = 60{,}000 \times 1.357$$

$$= \textit{say } 81{,}400 \textit{ cu.ft. per min.}$$

For the increased water gage due to 25 hp.,

$$\frac{w.g.}{1.057} = \sqrt[3]{2.5^2} = \sqrt[3]{6.25}$$

$$w.g. = 1.057\sqrt[3]{6.25} = 1.057 \times 1.842 = 1.947 \textit{ in.}$$

Coefficient of Friction

Ques.—What is meant by the term *coefficient of friction,* as used in mine ventilation? Give an example showing how such coefficient is used.

Ans.—For a full explanation of the coefficient of friction and its use in mine ventilation, see Coal Age, Feb. 24, p. 653.

Water Gage Required to Double Circulation

Ques.—If 20,000 cu.ft. of air per min. is circulated in a certain mine, by a water gage of 3.5 in., what water gage will be required to increase this quantity to 40,000 cu.ft. per min.; in other words, to double the circulation?

Ans.—For the same mine or airway, the pressure or water gage varies as the square of the quantity of air circulated. In other words, the water-gage ratio is then equal to the square of the quantity ratio. In this case, calling the required water gage x,

$$\frac{x}{3.5} = \left(\frac{40{,}000}{20{,}000}\right)^2 = 2^2 = 4$$

$$x = 3.5 \times 4 = 14 \text{ in.}$$

Sociological Department

For the Betterment of Living Conditions in Mining Communities

Human Element in Coal Mining

By Sim Reynolds* and W. H. Reynolds

During the last 25 years, we have had experience in mines of all kinds from the crudest, dug in the side of a low hill, to mines approached by deep shafts and as nearly perfect as human thought and effort can make them. And our experiences have driven home, like reiterated sledge-hammer blows, the conviction that perfection is far from being attained when the finest installation, mechanically speaking, has been completed.

No mine, no matter how costly may have been its development, no matter with what almost excessive care it may have been planned and its construction executed, is safer than the most careless employee permits it to be. The mine is always at the mercy of an illiterate and reckless foreigner, or of an over-ambitious, output-crazed mine foreman. The whole chain of caution, mechanical perfection and provision snaps at its weakest link, the human element.

The Near American Steps Aside for the Wholly Alien

Large capital is adopting improved machines and systems, the former more readily than the latter, but we face a difficulty which new mechanism and improved mining practice cannot over-balance. The apex of our former labor pyramid has become its base. While the immigrants, who poured into our coalfields, in the seventies and eighties numbered nine of British, German or Scandinavian nationality to one from other countries, now there is but one man from those countries to eight or nine Italians, Greeks and Slavs.

To quote the mine reports of the State of Pennsylvania in reference to underground labor:

> Information received from 98 per cent. of the operators shows that 40 per cent. of the employees are of the English speaking races, while 60 per cent. are non-English speaking. Of those killed, 73.62 per cent. were of the latter class, and only 26.38 per cent. were Americans, English, Scotch, Irish and German. If the accidents among these people had been proportionate to the total number of each class employed, 102 of the latter class of men would have been killed instead of 67.

*Pittsburg-Buffalo Co., Marianna, Penn.

Discipline Needed More Than Legislation

It is plain, therefore, to the most casual reader that the men in charge of mines where such conditions exist are working under a natural disadvantage, regardless of all the aid which may be given to the managements by generous mine owners. It will be seen at once that mining officials have a more difficult proposition than confronts any other men in charge of employees working in extra hazardous occupations.

James E. Roderick may be quoted again:

> Legislation of the proper kind would, no doubt, bring about a reduction of fatalities, but the most prolific cause, which is carelessness on the part of mine officials and employees, can be removed only by greater discipline, discipline which will enforce obedience to those laws and rules which have been framed to give a greater degree of safety, discipline that will mete out severe punishment to the man in charge, and to the employee alike, who, by their carelessness or recklessness, place the lives of the men in the mines in constant jeopardy.

Polyglot Foremen

The other day a suggestion appeared which is more humorous and decidedly less practicable than that quoted. It was made at a meeting of the American Society of Mining Engineers. In brief it was to the effect that the men in charge of mines should learn the languages of the different classes of workmen so that they could instruct every employee in his native tongue, regarding the rules of the mine and the observance thereof. The idea is good, very good indeed, doubtless too good to be generally carried into action in the great gas-coal fields. Evidently the speaker was never much nearer the average gas-coal mine than an office on Broadway or some such street in a large city.

If he had been, he would have understood that the foreman of an uptodate mine in a gas-coal region hardly has the time to express himself properly in English, certainly not in all the tongues of southern Europe. Unless he had learned the several languages when a miner, or while yet a boy in common school, he could scarcely hope to find such an easy berth that he would have sufficient time left in each 24 hours to become an efficient linguist, unless he could procure his education in this respect by a cash purchase.

If this be possible, we readily acquiesce in the proposition advanced, and think that in view of the chaotic condition of mine labor it would be a profitable investment for every mine operator to purchase an assorted dozen of linguistic proficiencies ready for use in each large mine, as many a foreman or superintendent in the gas-coal country could use them all, with the possible exception of Hebrew and Chinese.

The Care of Mine Mules

By Matthew J. Davies

The mule has never been supposed to possess any surplus brains, while, on the other hand, I believe it has never been given full credit for the intelligence it sometimes displays. Mules vary in their temperaments and dispositions, much as men do. Some are docile and tractable, others lively and spirited, and some are very refractory and even vicious. Occasionally, we have known them to lie in wait craftily for days and even weeks, seeking an opportunity to kick drivers who have mistreated them, and they sometimes accomplish their purpose with fatal results. But, on the whole, in my experience with mules, I have found that they readily respond to kindness, and are amenable to good treatment.

Improvement in Stables

As to care of mules, the first essential is a clean, comfortable and sanitary stable, with plenty of headroom, sufficient ventilation and good drainage, and an abundance of pure water, rather than the foul, ill-smelling and disease-breeding quarters in which mules are stabled in some collieries. The fact that the animal survives any length of time in some of the stables we have seen, despite the hard and severe toil, it is called upon to perform, is a remarkable tribute to its hardiness and endurance.

It is gratifying to note that during the last year, prompted by legislative enactment, a notable change has taken place along these lines. The mule is coming to his own, even though the reform is actuated more from fear of fire and its consequent results, than from any regard for the poor beast's comfort. But the Delaware, Lackawanna & Western R.R. Co. began improving its inside stables many years ago, before there was a hint of legislative compulsion.

There are four or five classes of workmen in our collieries, who come into personal contact with the mule. Upon

their intelligence, good judgment and exercise of common sense, its usefulness and efficiency, largely depend. These are the barn boss, the driver, the driver boss and the shoer, and we might also add, the car runner. The barn boss must feed the mules judiciously, and if an inferior grade of hay and grain is furnished, he should promptly report that fact.

The Barn Boss

The barn boss should be responsible for the proper preparation of a mule for work, see that it is properly cleaned, for which purpose curry combs and brushes must be provided. Sufficient time must be spent in cleaning and harnessing each mule. The barn boss must give special attention to the fit of the collars and thus prevent shoulder galls, which are caused in most instances by the collar being either too large or too small. Drivers should not, under any circumstances, be allowed to change collars. It is the duty of the barn boss to clean the collars every night, and for this purpose he should provide himself with scrapers. Next in importance to the collar is a well fitting hame.

On all harness, the trace chains must be equal in length, about 8 ft. long, composed of 4-in. links of 3/8-in. iron. To secure this when a trace is sent for repair, its mate must be sent with it. Leather chain pipes and special pads for the protection of the mule should be used when needed; also a strong leather cap piece on the bridle to protect its head.

The barn boss should be on hand every night to inspect the mules when they return from work and to see that no injuries have been received during the day. All injuries must be given proper attention at once. If the barn boss suspects the injury to be the result of carelessness or abuse, he should promptly report the matter to the mine foreman for investigation.

The barn boss must keep the barn dry and in good order. The stables should be cleaned every day and lime sprinkled on the floor every other day. Water troughs in front of the mules should be cleaned at least two or three times each week, and the food boxes cleaned regularly each day. Mules should be given fine salt twice a week, not mixed with feed, but placed in a little box provided for it on the manger. Stables should be lighted by electricity.

Mules should not be allowed to work for two consecutive shifts, except in cases of extreme necessity. Their hoofs should be kept in good condition, and each mule should be shod on all four feet once a month. When a mule is taken sick, the barn boss should immediately administer the proper medicine, of which a sufficient supply must be kept on hand. Cases of severe injury, accompanied with loss of blood, must receive prompt attention until the bleeding has ceased and the animal made comfortable. In addition to medicines, the barn boss must keep on hand other articles and supplies appropriate in emergency cases, such as oakum, cotton, bandages, antiseptics, etc.

Duties of Driver

Another important person in connection with the care and welfare of the mule is the driver. We cannot fail to realize this, when we consider that both are closely associated, as a rule, for about 10 or 11 hours each working day. Drivers should not drive their mules faster than a walk, either when working them or in going to and from the barn. As a rule, drivers are in a bigger hurry to get to the barn than to leave it, and are prone to compel the mules to trot and hurry, which severely tries them after a hard day's work.

Care of the Mule

When leaving mules, drivers should first tie them in a safe place, out of danger from moving cars, or other sources of injury. On descending grades, mules should always be unhitched from the trip and walked down behind it. They should always be led, never driven, through narrow places, for the instant they feel pressure in a narrow passage, they fear danger and make a sudden spring forward. I have known mules to receive serious injury in this manner.

When shifting cars into chambers, mules must not be driven beyond the last point at which they can turn easily, nor driven over loose coal lying on or beside the track. The practice of breasting cars into the chambers should be strictly prohibited. The summits of all grades, toward which mules are used to haul cars, should be furnished with safe and reliable headlocks, to prevent the cars from running against the mule. In fact, headlocks should be placed wherever necessary to prevent accidents. When ascending grades, drivers must have drags in place on the rear car of each trip.

Mules should not be allowed to pass under charged electric wires, and in returning to the barn, they should always be accompanied by the driver. The driver must also watch the feet of his mules, and, when shoes are lost, have them replaced at once. Mules must not be worked unshod.

Driver Bosses

The driver boss should confer and work in harmony with the barn boss in all matters relating to the care, protection and general welfare of the mules; and in order to do this, he should be in the barn every morning in time to see that every mule is properly cleaned and prepared for the day's work. He should also see that all haulage roads in his section are kept smooth and level with ashes or dirt and free from coal, rock and timber, and properly drained where necessary. Where headblocks or drags are required for the safety and protection of the mules, he should see that they are provided.

The driver boss and the barn boss should confer with each other and be careful when making up a team to select mules which will mate well. The quick and the slow, the dull and the nervous, the weak and the strong, should not be placed in the same team. This is an important matter, and cannot be given too much thought and consideration.

Where blocks and chains are used, the chains should be four feet long, and it should be borne in mind that, "no chain is stronger than its weakest link." The driver boss should never allow a miner to repair a broken chain with wire. In all cases where a block and chain is used, a drag should be attached to the rear of the car. Wherever two rails form an acute angle, into which a mule is liable to thrust its hoof, it should be properly wedged and blocked. The driver boss should also see that all trace chains and spreader sticks are of proper length. The dimension of the latter is dependent on the track gage, the standard lengths being 31 and 33 inches.

No side hitching should be allowed unless there is ample room to do so without any danger of injury to the mule. Mules should not be changed from one working place to another without sufficient reason. A change may be necessary sometimes, in order to lighten their work.

Great care should be exercised in handling a green mule. It should be first placed in charge of an experienced driver, given light work, and gradually broken in, until trained and fitted for the regular and more difficult work. Overloading or overworking a mule cannot be too strongly condemned. After the mules have left the barn, the driver boss should spend as much time as possible near them and their drivers, and insist that the former receive good treatment and a square deal.

My sympathy is with the poor animal, which is compelled to perform hard, grinding toil, in more or less dust and smoke, for nine or ten consecutive hours without even a drink of water or a grain of food. At little expense, 1/2-in. or 3/4-in. pipe line could be laid to central locations, through which water could be conveyed to a trough, and at noon the mules could be watered with little loss of time.

Every driver could be furnished with a canvas nose bag, containing a small quantity of grain or corn for the mule to eat while the driver is having his own dinner. The renewed vigor with which the mule would attack its work and the resulting gain in efficiency would, in my opinion, amply repay the loss of time, if any, and the expense incurred.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

Dr. J. A. Holmes, of the Bureau of Mines, has made a statement before the House Committee on Appropriations concerning the investigations of the bureau. This has just been made public. He asks for arrangements that will concentrate the work more largely in Washington and will render it more efficient.

Dr. Holmes states that the work now being done outside the bureau offices and laboratories is as follows: At the University of Ohio, a study of clays is being made in connection with general quarry or mineral products; at Princeton, chemical work is conducted in relation to mine accidents. This should go partly to Pittsburg and partly to Washington. At New Hampshire College, work relative to mineral wastes is being carried on.

"We get the supervision of the university men free," he adds, "but we have a man at the University of Ohio, for example, in our own employ, whom we want to bring here. There is great advantage in having all these men and their work brought to Washington; but unless the bureau can get the increase in space asked for, it will be compelled to send other men out to such institutions as will give us space rent free. We are studying clays and other products from the quarries examined, in connection with the quarry methods, and the action of clays and various mineral substances, on coal and ores, and other substances of that kind."

It is expected that the changes thus requested will be made. With further reference to the need of new quarters, Dr. Holmes says that when the present building was arranged for, only about 33 persons were connected with the work of the Bureau of Mines in Washington. At the present time, the building is occupied by between 90 and 100 people. "So the situation today is that the Bureau of Mines is exceedingly crowded in its work, and cannot continue its work efficiently within the limited space of this building."

Market for Alaskan Coal

The Senate has had printed as senate document No. 573, a partial report of the proceedings of the fourteenth annual convention of the American Mining Congress, under the title "Alaskan Problems." It is interesting to note that the problem which figures most prominently in this document is the mining and transportation of coal.

Special attention is given to papers on this subject and notably to a discussion of "Coal Transportation in Alaska." In this paper, great stress is laid upon the question of a market for the coal, stating, in part, that:

It is doubtful if there is a market for much Alaska coal outside of Alaska. Eastern people and those of the Middle West do not appreciate that there is plenty of coal on the Pacific coast, much more accessibly located than that of Alaska, besides fuel oil in abundance, and the most marvelous hydro-electric power in the world. Even in Alaska the Treadwell mines and the Copper River R.R. are being operated by California fuel oil, and it is evident that Alaska steaming coal has little demand upon the Pacific coast of the United States in the face of such competition. A market will ultimately be made for some Alaska anthracite, and the Alaska coking coal will be of great importance, especially in the treatment of the low-grade copper ore along the Alaska coast. The United States Navy, which is now importing coal from West Virginia, might save the price of a battleship in a few years by using Alaska coal, but the Alaska fields really have little bearing upon the great question as to the future policy for the disposition of coal lands upon the public domain of the United States. Some new system must be adopted in Alaska, however, and consequently this subject has been given mature consideration. Two methods have been suggested: One a leasing system, and the other, government operation of the coal mines.

Alabama

Birmingham—An explosion took place in the third right heading, bottom slope, of the Roden Coal Co.'s mine at Marvel, Bibb County, Ala., at approximately 10 a.m., Apr. 30. This resulted in the injury of eight men. None of them was seriously burned, although one was nearly dead when rescued, from suffocation.

At every mine in the Cahaba coal field there is more or less gas. In the Marvel mine, gas has only shown up on four out of 28 headings, and in very small quantities. The explosion was caused by a driver carrying an open lamp by a room in which men, employed by the company, were fanning out the gas to make the room safe for working the next day. That the amount of gas was small is evidenced by the fact that there was very little concussion, merely a sheet of flame, which lasted only a few seconds. The force of the explosion was not felt on the surface and in but few of the other working places. The news was telephoned to the top, and immediately a rescue party was organized. All the air was thrown from the top slope to the bottom slope, giving it double the usual quantity.

Helena—It is generally rumored here that the Wadsworth Red Ash Coal Co. is negotiating for a lease of the old No. 2 mine, from the Tennessee Coal, Iron & R.R. Co. It is also stated that the Red Ash company will purchase the Otto Marks property which adjoins the No. 2 mine. The properties lie about two miles from Helena and if the negotiations are successful it is expected that operations will begin at once.

Colorado

Denver—Coal operators in the southern Colorado district have consented to recognize the check weighing system and hereafter this system will be in use at the Green Cañon, Suffield, Royal, Shaft and Empire mines. Union weighmen have been reinstated in all mines in the Aguilar district. The men also have been granted a "checkoff" of the checkman's wages. This recognition has been the direct result, it is claimed by union labor leaders, of the efforts of the United Mine Workers' organization in this state.

Pueblo—By a compromise effected between the federal land office and the Denver and Rio Grande R.R., 8465 acres of coal lands in Colorado, having a market value of $1,755,750, held by the Atlas Utah Fuel and the Calumet Fuel companies, subsidiaries of the railway system, have been conveyed back to the United States government and will be thrown open to purchase. The lands are situated in Gunnison and La Plata counties and comprise some of the best bituminous coal deposits in the west. The largest tract is in La Plata County and embraces 5385 acres of unpatented and 640 acres of patented lands. Close to the city of Pueblo is a tract of 400 acres and the remaining 840 acres are in Gunnison County. The last named acreage is the most valuable, there being 8 seams, which have a total thickness of 70 feet.

Illinois

Panama—An explosion in the mine of the Shoal Creek Coal Co., recently killed two men who had been left in charge of the mine, which was idle at the time.

Other men who were in the mine escaped without injury.

Canton—The tipple of Star mine, No. 2, burned to the ground recently before help could arrive to extinguish the flames. The fire is supposed to have been started by lighting, but the blaze did not break out until about half an hour after the storm. The tipple was built 5 years ago and will probably be rebuilt inmmediately as there is still much good coal on the property.

Republic—The Interurban Electric Co., which operates an electric line between Carterville and Herrin, Ill., has been reorganized by officials of the National Light & Power Co. of St. Louis, who have arranged to extend the service to the coal-mining district of southern Illinois. St. Louis capital will finance the proposed extensions. The present plan is to extend the line from Herrin through the towns of Craneville and Reeves, and to supply power for the operation of the coal mines, of which there are about 60 in the territory reached. The present headquarters of the Interurban company are at Carterville, Ill.

Indiana

Terre Haute—Indiana coal operators and members of district No. 11 United Mine Workers, after three sessions of the joint wage conference, which opened at Terre Haute, Apr. 30, were no nearer an agreement than they were at the beginning of the conference. The question of resuming work at the mines pending a settlement of all differences and demands was the principal contention, and a motion advocating resumption made by Mr. Penna was promptly voted down by the miners. It now looks as though there will be weeks of parleying before an agreement will be reached and work resumed. This is unfortunate and disappointing because the demand for coal is becoming persistent. The operators charge that the miners are going beyond their sphere in trying to set the price of powder, the selling price of coal and in making other demands. Some of the demands made by the men are:

> A weekly pay. A reduction in the price of blacksmithing to ½c. on the dollar on the gross earning for pick miners and nothing for machine miners. A charge of $1.25 a keg for powder. That when a part of a mine is shut down the men so affected shall be entitled to their share of work in the parts of the mine that continue at work. That a reasonable price for house coal be charged from those working in or around the mines. Reasonable price not to exceed 5 per cent. of actual cost. That where a company wrongfully stops a man's turn such company shall remunerate him for time so lost.

A deadlock likewise has been reached by the scale committee of District No. 8 meeting at Brazil, and there is no indication of an early settlement. The matter has been referred to a sub-committee composed of four miners and four operators. The operators refuse to even consider the clause which provides that they shall not discriminate in the employment of men on account of creed, color or their activity in matters affecting the miners' union. The operators declare that they have a perfect right to consider the kind of men that they employ, and under no circumstances will they sign the scale containing a clause which provides for the employment of men in the order in which their cards are deposited. The miners insist that this clause must stand.

Kansas

Pittsburg—Two new coal companies have recently been organized to conduct stripping operations in this vicinity. These are the Nesch Coal Co. and the Pittsburg-Scammon Coal Co. The latter concern is allied with the Pittsburg Brick Co. and will not place its product on the market to any great extent.

Kentucky

Louisville—Failure to agree upon an interpretation of the Cleveland wage-scale compromise which was to be the basis of settlement between the miners and operators of western Kentucky, led to a proposition on the part of the Western Kentucky Coal Operators' Association to submit the matter to arbitration. The wages offered by the operators will be submitted to a referendum vote of the miners. The mines affected have been idle for more than a month pending a settlement of the questions at issue.

The Interstate Commerce Commission has suspended, until Nov. 1, tariffs of the Louisville & Nashville R.R., advancing rates on coal and coke from points on its line to points on the Big Four. The rates were to have become effective May 1.

Providence—The coal mine and other property of the Fairmount Coal & Mining Co., of Providence, will be sold at public auction May 22 Glenn R. Fudaley, of Madisonville, Ky., is trustee in bankruptcy for the company.

Whitesburg—The Schoberth Syndicate of Philadelphia, has purchased 5000 acres of coal and timber land along Carr's Fork and Beaver Creek in Knott County.

Henderson—Thinking he was hoisting a load of coal the engineer of a mine at Clay, Ky., recently ran the cage up hastily and dumped it, dropping a miner 100 ft. to the bottom of the shaft and killing him instantly. Two others were hurt.

Ashland—A new company has been incorporated in Kentucky by officers of the Norfolk & Western Ry. Co., to build a line from Williamson, W. Va., to Pikeville, Ky. It will be 20 miles long, with branches, and is to be completed by June 1, 1913.

Missouri

Kansas City—Conferees representing coal miners and operators of the Southwest have renewed their agreement that there shall be no suspension of operations while negotiations for a new contract are pending. This provision of the old contract expired May 1. It is said that the sub-committee which is considering the arbitration clause of the new agreement is making good progress.

Montana

Missoula—After a thorough examination, the Butler Creek Coal Co. is about to commence active development work on its properties located between La Valle Creek and Butler Creek, about seven miles from Missoula. A shaft is now being sunk to a coal seam having a thickness of between 5 and 6 ft. The coal is a lignite of the miocene formation and carries only about 4 per cent. of ash. It is particularly adaptable to briquetting, and with this treatment its fuel value will be increased materially. It is proposed to install a briquetting plant in the near future.

Ohio

East Liverpool—Six thousand acres of valuable coal land, north of East Liverpool and Wellsville have been taken over by the West Point Coal & Coke Co. Confirmation of this deal, the most extensive in some years, was secured recently from J. L. Francis, president of the company. The deal involves an immediate outlay of from $100,000 to $150,000. It is conjectured that the purchase means an early beginning on the construction of the proposed Ohio River & Northern R.R. from Midland, Penn., past East Liverpool and Wellsville and thence to West Point. Mr. Francis stated that the newly acquired coal lands for the most part face the railroad right of way. The opening of this coal territory means direct delivery to the Crucible Steel company's plant at Midland, Penn. This company is spending over $5,000,000 in improvements. The exact boundaries of the property acquired by the West Point Coal & Coke Co. have not been announced. However, it extends from about three miles back of Wellsville, north for a distance of five miles to West Point.

Columbus—A ruling by the State Public Service Commission makes the Hocking Valley R.R. Co. liable for a number of damage claims on short weights. A test case was brought, to determine whether or not the practice of underbilling coal 1000 lb. to the car, released the carrier from shortage claims when a car arrived at destination with contents un-

der the weight called for by the shipper's bill of lading. Underbilling has now been done away with, but the case was filed under the old system. Other claims that have arisen will now be pressed. The railroad company will probably carry the matter into the courts.

Massillon—A committee representing the operators and miners of subdistrict No. 3, of district No. 6, United Mine Workers, met here May 1, to draw up a wage contract for the next two years. The cost of supplies, such as oil, powder, and house coal promised to be the principal bone of contention. The committee have no power to change the basic scale of $1 a ton and proportionately increased wages for other kinds of work, fixed by the Cleveland conference in March. They will deal exclusively with questions arising out of conditions that exist in this sub-district.

Pennsylvania

Bituminous

Pittsburg—Maintaining that the reduction of 10c. a ton in the freight rate on coal from Pittsburg to the lakes, recently ordered by the Inter-State Commerce Commission, does not grant them the relief desired or necessary to enable them to compete with West Virginia, the Pittsburg coal operators, through John W. Boileau, with the Pittsburg Coal Co. intervening, have filed another petition asking for a further reduction in the rate. They want the rate reduced to 50c. a ton, the figure named in the original petition; but whether this is granted or not, they hold that the Inter-State Commerce Commission should further modify the rate.

Waynesburg—Josiah V. Thompson and associates of Uniontown have closed a deal by which they have sold to Edward H. Jennings of Pittsburg 2896 acres of coal and 220 acres of surface located in Washington township, Greene County. It is reported that $780,000 was the amount paid. The land is on Ruff Creek. It is west of the holdings of the Emerald Coal Co. and is bounded on the north by holdings of the Westmoreland Coal Co. Thomas Ross of Washington township, Greene County, sold to Thompson, 370 acres of coal land on Ruff creek, for $131,000. The purchase of the Ross property gave Thompson possession of the tract which amounted in all to about 3000 acres.

Du Bois—Reports from the locals of district No. 2, United Mine Workers, indicate that the referendum vote of the men will ratify the wage-scale agreement which was reached at a conference here several weeks ago.

The contention between the Cascade company and their Sykesville miners over the taking in and out of cars has been adjusted and the mine resumed work recently after a suspension of over a month. Not all the men returned to work at once, as it will require some time to get the big plant in full operation and the entire 600 miners and cokers back at work.

The coal mines at Savan, Indiana County, which have had a hard time of it, financially and otherwise, are at last to be opened up and put in active operation. Work was commenced recently on a new tipple and also on a new opening.

Brockwayville—According to reports, the Shawmut Mining Co. is preparing to open up a coal field in the Shawmut valley that has hitherto remained undeveloped. The main opening will be in the vicinity of former operations at Shawmut which have been closed down for several months and sufficient territory will be tapped at once to insure the employment of a large number of men.

Anthracite

Scranton — Women were the leaders in a riot in the Scranton district May 7, leading a force of men in an attack upon repairmen at the Dickson shaft of the Delaware & Hudson Co. at Green Ridge. Forty repairmen were routed by 500 men, women, and children. Four of the 40 fell in their tracks, and two of them were seriously injured. The rioters gathered at the colliery as the 40 men reported for work, which the union had said they were privileged to do. The mob was made up of foreigners, but many English-speaking people joined in the attack because they were led to believe that some wrong had been committed, and that they were justified in taking the law into their own hands.

Wilkes-Barre—At a conference of the general scale committee of anthracite miners and operators, held in New York, May 2, the representatives of the miners refused to accept the terms of the agreement which was reached by the subcommittee of four operators and four miners on Apr. 25. A general convention of mineworkers of the three anthracite districts has been called to meet in Wilkes-Barre, May 14 and the question of ratifying the proposed agreement will be decided at that time. The operators decline to enter into a further discussion of the matter, insisting that the men should endorse the work of their committee. In the event of the miners refusing to do this the proposition of the owners to refer the controversy to a strike commission still remains as a basis of negotiations.

Mayor John V. Kosek has notified the various coal companies with mine workings under the city, to send maps of their mines to the city clerk. The action of the mayor followed a mass meeting of the citizens of North Wilkes-Barre, who have taken steps to protect their homes from surface subsidences.

Shenandoah—Serious riots took place here and at Mt. Carmel on May 6, and some trouble of the kind was also experienced at Mahanoy City. The rioters were Italians. They went armed upon the highways and clubbed and stoned workmen, overran two collieries, and prevented union men from reporting for work, which the union had declared permissible.

At Mt. Carmel, the rioters took up positions along the road leading to the Richards colliery of the Susquehanna Coal Co. Four union men were stopped and the rioters beat them until they were helpless. The rioters then marched to the Sayre colliery of the Lehigh Valley Co. and stretched ropes across the roadway, refusing to permit workmen to leave the colliery, and refusing admittance to those who wanted to work.

At Shenandoah the rioters started marching early. They went to a stripping and drove away the men and then went to the William Penn Colliery of the Susquehanna Coal Co. and the Shenandoah City Colliery of the Reading. Pumpmen, engineers and firemen were driven from their posts and the rioters refused to allow anyone to work. The sheriff sent to Pottsville for a squad of state troopers and they charged the rioters and drove them from the highway. The police remained upon the scene and are patrolling the highway.

West Virginia

Clarksburg—The mine of the High Grade Coal Co. at McWhorter, near here, was placed under a heavy armed guard Apr. 27, following threats of striking miners to blow up the mine with dynamite. The situation in the coal fields became so menacing that calls were momentarily expected to be made on Gov. Glasscock for state militia.

Charleston—The miners and operators who have comprised the subscale committee in conference here formulated a wage agreement on May 1 which was ratified immediately by the miners in convention, while the operators now have the proposition under discussion. Under the new agreement the Kanawha miners will receive one-half of the increase stipulated in the Cleveland wage scale and the semi-monthly payday will be restored. The miners abandoned their demand for the check-off system.

Wellsburg—About 600 acres of coal land, the tipples, cars and equipment of the La Bell Coal Co. have become the property of the Lewis Finley Co. and it is expected that the new concern will greatly increase the coal output of this section.

Welch—Contributions to the Jed relief fund asknowledged by H. N. Eavenson, Gary, W. Va., secretary of the committee, up to May 2, amounted to $12,030.66.

Personals

E. L. Sternberger, of the E. L. Sternberger Coal Co., Cincinnati, recently made a business trip to Chicago, Cleveland, Toledo and other Lake cities.

Carl Scholz and W. H. Skaggs, both of Chicago, Ill., are prospecting a large area of coal land, presumably in the Corona Seam, in Walker and Fayette Counties, Alabama.

William Monay, superintendent of the Central Coal & Coke Co.'s coal mines, at Rock Springs, Wyo., has accepted a position as assistant general manager of the Kemmerer Coal Co., and will enter upon his new duties at once.

Frank H. Crockard, vice-president of the Tennessee Coal, Iron & R.R. Co., has returned to Birmingham from New York, where he attended a meeting of the rail committee appointed by Judge E. H. Gary, of the Steel Corporation, to discuss the betterment of steel rails.

C. P. Collins, civil and mining engineer, of Johnstown, Penn., has been appointed mining engineer of the Berwind-White Coal Mining Co., with headquarters at Windber, Penn. Mr. Collins has leased his engineering business in Johnstown to S. E. Dickey, preparatory to taking up his new duties.

A. B. Jessup, mining engineer of the Lehigh Valley Coal Co., Wilkes-Barre, Penn., has resigned, effective May 1, to become general manager of the J. B. Markle coal properties, at Jeddo, Penn. Mr. Jessup was tendered a banquet by the employees of the Lehigh Valley company, on May 4, and will take up his residence in Jeddo in the near future.

C. P. Ludwig, general superintendent of the Alabama Consolidated Coal & Iron Co., and S. B. Sheldon, of New York, representing a large number of men financially interested in the properties of the Southern Iron & Steel Co. and the Alabama Consolidated Coal & Iron Co., were in Birmingham recently, inspecting the properties of the two companies.

E. Kelly Rothstein, formerly vice-president and general manager of sales for the Davis Coal & Coal Co., has become manager of the Messrs. B. Nicoll & Co.'s coal and coke department, with offices in the Singer Building, New York. The latter company has been appointed sales agent for the Davis Coal & Coke Co. in all territory except New England.

William L. Martin, for several years assistant superintendent of Pratt No. 1 division of the Tennessee Coal, Iron & R.R. Co., who, on Apr. 1, this year, was engaged by the State of Alabama as superintendent of the Banner mine, has resigned this position, effective at once. The Banner mine is being operated with convict labor by the state for the Pratt Consolidated Coal Co., of Birmingham.

Chronology of Coal Mining for April

Apr. 2—Complete suspension of work at anthracite mines of Pennsylvania and at a large proportion of bituminous mines in central competitive field.—Wage increases granted in southern Colorado field.

Apr. 6—Coal strike in Great Britain officially declared at an end.

Apr. 10—Bituminous miners ratified Cleveland wage-scale agreement by a referendum vote of 109,709½ to 32,139½.—Conference of anthracite operators and miners opened in Philadelphia.

Apr. 18—Fifty thousand miners in Pittsburg district returned to work.

Apr. 20—Central Pennsylvania operators and miners agreed on a two-year contract.

Apr. 21—An explosion of gas in the Coil coal mine, Madisonville, Ky., killed six men.

Apr. 25—Two-year bituminous wage contract formally signed at Indianapolis. —Subcommittee of anthracite operators and miners reached wage-scale agreement.

Apr. 30—Explosion in Hokkaido Coal Co.'s mine, Yubari, Japan reported to have entombed 283 men.—Miners in southwestern field agreed to remain at work pending the signing of a contract. —Explosion in Roden Coal Co'.s mine at Marvel, Ala., injured 8 men.

Book Review

THE USE OF MICE AND BIRDS FOR DETECTING CARBON MONOXIDE AFTER MINE FIRES AND EXPLOSIONS. By Geo. A. Burrell. Technical Paper No. 11, Bureau of Mines, 1912. Paper Covers. 15 pp., 6x9 in. No. illus.

This is a valuable monograph, but as it contains, to all appearance, nothing new, there would seem, therefore, no reason why it should depart from the announced purpose of the bureau to make these technical papers easy for the average miner to understand. How, for instance, he would stumble over the words, "physiologically indifferent," on page 7, is not clear. The bulletin contains a complete account of the properties and sources of carbon monoxide and the dangers to be apprehended from it.

It discourages the prevalent idea that a small percentage of monoxide will form a cap and will warn the miner of danger. Mr. Burrell declares that less than 2 per cent. of carbon monoxide cannot be detected by the use of a lamp, a percentage which would kill a man in a few seconds. Some short remarks are made on the chemical tests used for determining the presence of the gas. The last section treats of the action of monoxide on birds and mice and of their use in exploration of mines after an explosion.

Construction News

Viper, Ky.—The Kelley Coal Co. is considering the construction of a coking plant at Viper.

Nanty-Glo, Penn.—The Estep Coal Co. has under consideration the complete electrification of the Nanty-Glo mine and contemplates making an additional opening.

Salt Lake City, Utah—The Castle Valley Coal Co. has increased its capital stock from $5,000,000 to $7,500,000, to provide a new tipple at Mohrland and make other improvements.

Boswell, Penn.—The Merchants Coal Co. contemplates opening a new mine and making necessary improvements to tracks, yards, etc.; $25,000 will be expended on the erection of miners' houses.

Red Ash, Ky.—The Proctor Coal Co. will develop several additional mines to a total daily output of 2000 tons. Machinery will be electrically driven. Charles F. Finley, Williamsburg, Ky., is president.

St. Paul, Minn.—The Pittsburg Coal Co. has taken out a permit for the erection of a coal elevator on East Eighth St., to cost, with machinery, about $4000. The building will have a storage capacity of 2500 tons of hard coal.

Morgantown, W. Va.—Mine No. 7, of Elkins Coal & Coke Co., is now being opened up, two miles southwest of Bretz, and it is estimated that the actual mining of coal will be under way within three months. A tipple, houses, stores, tracks, etc., are to be built.

Ashland, Ky.—The Kentucky Solvay Coke Co. has purchased a 65-acre site in this city and plans the immediate construction of a large coking and by-product plant. The cost of the plant will total $900,000, it is stated. The tract which has been secured was purchased from the Ashland Coal & Iron Co.

Birmingham, Ala.—A. H. Woodward, vice-president and general manager of the Woodward Iron Co. has announced that $2,000,000 will be spent on improvements to the company's properties. It is estimated that $1,000,000 of this will be applied to the mining properties, but no definite plans for this work have been announced.

Shamrock, Ky.—The Climax Coal Co. has organized with Edward L. Douglass, vice-president and general manager, and has taken over the Edgewood Consolidated operation at Shamrock. It is making numerous improvements. Shaker screens, a washer and other modern equipment are to be installed. The Hignite seam will be opened.

Louisville, Ky.—The Oliver Chilled Plow Works, of South Bend, Ind., is reported to have purchased 15,000 acres of coal and timber land in Harlan County, Ky., for immediate development. The land was purchased from the Wisconsin Steel Co., a subsidiary of the International Harvester Co. The steel company now has several hundred coke ovens in operation in Harlan County.

Cincinnati, Ohio—The Reliance Coal & Coke Co. has determined to expend about $20,000 in modernizing the property formerly occupied by the Cincinnati Gas, Coke, Coal & Mining Co., recently purchased by Julium Fleischmann and associates, at the southwest corner of Blair Ave. and Weatherhead St., Avondale. A new system of overhead trestles, bins and a modern stable will be installed, the work to be started in the near future.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The opening of the Lake trade and the unexpected deadlock in anthracite have steadied the market up materially. Hard-coal supplies are down to a low point, and the unprecedented action of the miners in rejecting the scale fixed by the sub-committee is causing considerable apprehension among consumers. This has also had a stimulating effect on bituminous and tended to check a further decline in this branch, which has about held its own during the past week. The outlook in soft-coal is not, however, so bright, as there are still evidences of strike surpluses, and some difficulty is experienced in placing the new arrivals which are again about normal.

The Eastern bituminous market is settling down to the usual spring dullness, although fairly active and with a satisfactory movement. The arrivals are mostly on contract and are naturally slow, due to the heavy shipments in March and April. Very little anthracite is coming in, but there is as yet no evidence of any particular distress over the shortage in this grade. Production in the Pittsburg district is increasing, but is still low, probably only about 50 per cent. capacity. The new circular of the Pittsburg operators has not been severely tested as yet, but there is already tangible evidence that it will not hold.

The Ohio mines in the Lake trade are starting up and operators are anticipating a banner season in that market this year. Production in West Virginia has eased off some, but the tonnage dumped at the Virginia piers during April was the highest on record. The union mines in the western Kentucky fields are still closed, and the demand is light, although a good season is expected. In the Middle West there is a fair buying movement, principally from the railroads and large steam users, and the market is somewhat stronger.

Boston, Mass.

The bituminous market is settling down to the usual spring dullness. Prices are easy on only a slightly higher basis than last year, but buyers are not showing the interest that was expected. The few cargoes of Southern coals that arrive are mostly on contract and for the largest consumers. Inland trade is well supplied for the present and it will take lower prices than now prevail to induce any buying, ahead of actual needs.

Reading transportation is still available for bituminous out of Philadelphia and a fair tonnage is coming from Pennsylvania in that way. All the shippers are in a position to clear boats promptly. Transportation generally is easy, with rates from Hampton Roads at 70c. or less for large boats.

Shipments all-rail are rather slower than usual for this season, due to the heavy volume moving in March and early April. Few contracts are reported placed, and those only by large concerns, and at prices little if any in excess of last year.

The news of the disagreement in the anthracite scale conferences, following the meeting May 2, came as a surprise. If negotiations are much further extended the dealers will be getting apprehensive again. There is practically no premium coal offering, and so far as the trade goes, hard coal is at a standstill.

In Boston retail contract prices on soft coal are $4.50 to Oct. 1, and $4.75 from Oct. 1 to Apr. 1, net tons delivered, or 25c. higher than last year.

Wholesale prices are about as follows:

Clearfields, f.o.b. mines	$1.10@1.35
Clearfields, f.o.b. Philadelphia	2.40@2.60
Pocahontas, New River, f.o.b. Hampton Roads	2.70@2.80
Georges Creek, f.o.b. Baltimore	2.60@2.70

New York

The refusal of the anthracite miners' full committee to ratify the agreement reached by the subcommittee, resulted in a decided stiffening in the hard-coal market here the early part of the week. While the larger companies continue to quote their regular circular, they concede that there is little or no coal available at these figures, and that there are prospects of an acute shortage should the lockout continue. Coincident with the announcement of a break in the wage-scale conferences, the dealers withdrew the low prices put in effect May 1 on the supposition that this matter had been settled, and domestic is now back to the full March circular.

The bituminous trade, in sympathy with the anthracite, developed some strength during the past week, in that no further decline was in evidence, as has been the case during the past month. Spot quotations are slightly higher than last week, the lower grades being quoted around $2.65, f.o.b., with the better grade Pennsylvanias about $3.05. Some demurrage coal was disposed of at $2.50, but this cannot be considered the market. The trade reports plenty of fuel available, and the large operating companies say the mines are working well up to capacity and normal tonnages for this period are coming in.

The anthracite companies do not expect operations to be resumed at the mines before June 1. While buyers in the open market find it necessary to pay substantial premiums, the companies continue their regular circular as follows:

Broken	$4.50
Egg and stove	5.00
Chestnut	5.25
Pea	3.25
Buckwheat	2.75
Rice	2.25
Barley	1.75

Pittsburg

Bituminous—There has been a slight increase in activity at the mines in the Pittsburg district, but production is still far below normal and hardly amounts to more than one-half capacity. The stocks accumulated by consumers are still in evidence, so that buying is light. Shipments in the lake trade were started May 1 but have not yet reached important proportions, little coal being loaded since navigation is only getting started. Only a few vessels started last week on the down trip from the head of the lakes, ice having interfered to a much later date than usual. The new season prices have not been seriously tested as yet, but there is already tangible evidence that they will not hold universally. We repeat them, however, as there is no other basis for quotation: Mine-run and nut, $1.22½; ¾-in., $1.32½; 1¼-in., $1.47½; slack, 82½c. per ton at mine, Pittsburg district.

Connellsville Coke—Production is back to normal, about 400,000 tons weekly, and the prompt furnace market has grown still easier. There is little coke offered, but demand is almost equally limited. There have been negotiations on second-half contracts for furnace coke, but none appear to have reached a head yet. There is no reason to believe the recent report that a contract for the second half has been made at $2.35. Foundry coke continues in fair demand. We quote: Prompt furnace, $2.40@2.50; contract (nominal), $2.25; prompt foundry, $2.75; contract foundry, $2.40@2.50, per ton at ovens.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending Apr. 27 at 401,-

494 tons, an increase of 5000 tons, and shipments at 4313 cars to Pittsburg, 6281 cars to points West and 1288 cars to points East, a total of 11,882 cars, or an increase of 228.

Philadelphia, Penn.

The unexpected developments of last week entirely changed the situation in the anthracite trade. It was confidently expected that it was a mere matter of form for the general committees to confirm the findings of the subcommittees of the operators and miners, but opposition developed which will more than likely postpone operations at the mines for at least a couple of weeks. The first of June is now the prediction for a resumption of work at the mines, and this entirely dependent on the attitude of the convention to be held on May 14, at Wilkes-Barre.

The idleness of the mines is not, however, causing any particular stress up to the present time. There seems to be a fairly plentiful supply of coal for domestic purposes, and the storage supplies acquired by the manufacturing interests and other steam users early in the spring, seem to be holding well. Of course, some sizes are very short, notably pea coal, and this seems to be the rule rather than the exception, although there are a few dealers who are fairly well stocked on this size, and claim that they have sufficient to carry them for a month or so.

Spasmodic arrivals of anthracite are reported, some domestic sizes and a little buckwheat coming in, but most of the dealers are doing very little beyond looking forward to the announcement of prices and the resumption of work at the mines. Nothing definite has been announced as yet regarding prices or what the policy will be, and the operators are noncommital when asked as to what changes, if any, are likely to be made. The invariable reply is that prices will not be discussed until there is a definite understanding with the miners, and until this takes place, it is useless to speculate.

Baltimore, Md.

A strike among the laborers employed at the coal piers of the various railroads in Baltimore, arose during the past week, which seriously interfered with business in the local market. For two days matters were simply at a stand-still at both the Curtis Bay pier of the B. & O. R.R., and the Port Covington piers of the W. M. Ry., and as the differences between employers and employees have not yet been settled, there is no telling just how long present conditions will continue. The laborers employed to unload at the piers have been receiving 20c. per hour, while the coal trimmers, who handle the fuel after it is loaded on the steamers, have been paid 25c. per hour. The men have struck for an increase of 5c. an hour, and recognition of their union. The railroads will probably act together in any settlement which might be made.

Buffalo, N. Y.

The bituminous market sagged slowly all the week, till there came news that the anthracite miners might not go to work right away, when there was a visible stiffening. After two or three days it again looked as though there would not be a strike, which left the market weak again. There is plainly more bituminous coal mined than is needed, even though a good many mines returned to work only partially, or to meet business in sight. A week ago the reports made by the bear members of the trade that they could get Allegheny Valley mine-run for 95c. at the mines was stoutly denied by operators, but there appears to be much truth in the statements now, though some mines are refusing such offers and would close rather than accept them.

All that can be done in the line of quotations is to repeat former figures, which some are getting and some not, as follows: Pittsburg three-quarter, \$2.87½; mine-run, \$2.47½; slack, \$2.25, with Allegheny Valley about 25c. lower. Coke went too high and is now suffering a reaction, being down to \$4.50 for best Connellsville foundry.

There seems to be plenty of anthracite in Buffalo and none of the consumers have so far complained, but there is none for Lake shipment, though the demand in that branch of the trade is urgent. It now looks as if it would be impossible to meet that demand this season, even if mining should begin very soon. The anthracite operators always take care of the Eastern trade first and regard the Western trade as a sort of an overflow.

Columbus, Ohio

Within the past week, mines have started up in both the Hocking and eastern Ohio fields; this activity is confined largely to the lake-shipping companies. Though the ice in the upper channels makes it uncertain as to when the first fleets will be able to move, cargoes are being taken on by boats in their winter quarters at the Ohio ports. Coal will also be loaded on cars and held at the mines ready for movement to the docks as soon as navigation is fairly under way.

Aside from the Lake trade, the market is lifeless and mines might remain idle for several weeks to come without inconvenience. Stocking of fancy domestic coals, which usually sets in early in May, is slow, as dealers seem inclined to take a breathing spell after an exceptionally busy winter and spring. The prospects, however, are for an excellent business along this line. Owing to the increased cost of mining, producers will attempt to hold summer domestic prices well up to the formal circular of \$1.50, although this figure will probably be subject to some shading at the outset.

Fine coal is on the down grade with respect to price, because of the large tonnage that will soon accumulate as a by-product of lump in the Lake trade. The average selling price has dropped to 75c. and there is only a fair demand. Railroad fuel and mine-run for general industrial purposes is suffering from a period of readjustment, many big consumers still having storage on hand. This is having a bad effect on the closing up of contracts. Many large steam users seem inclined to take a chance on the open market for the coming year's requirements.

Hampton Roads, Va.

While there appears to be a lull in the market, coal has been moving quite freely through Hampton Roads this week, and prices are still good, though probably from 10 to 25c. less than last week.

Shipments here during the month of April set up an enviable record, reaching the high mark of 1,213,164 tons, and exceeding any previous for a month's loading at this port. These figures exceed by 94,014 tons the shipments during the month of March, which hitherto had been the record month, and is at the rate of 14,557,968 tons a year.

Both the Norfolk & Western at Lamberts Point and the Chesapeake & Ohio at Newport News, broke all their previous records. The Virginian Railway at Sewalls Point fell considerably below its usual dumping and was the only rail road that did not have a big month, which was due to washouts and other troubles.

Lamberts Point easily led the others, having a total dumping of 571,187 tons during the month, or an average of 21,968½ tons a day for the 26 working days. Newport News was second with a total dumping of 475,801 tons, while Sewalls Point was last with 166,176 tons.

From present indications the coal railroads at Hampton Roads are entering upon the greatest prosperity in their existence. While a great part of the increase in shipments from Hampton Roads was caused by the strike in England, considerable of the business will be held. The English strike was the opening wedge for Pocahontas and New River coal shipped from Norfolk and Newport News into ports heretofore supplied by Welsh coal exclusively and it has proved so satisfactory that new and steady markets have been opened.

Charleston, W. Va.

Practically all the mines in the Kanawha district are again in operation, after about two-thirds of them had been idle for a month, owing to the failure of the operators and miners to get together on the wage question. The settlement of the difficulty late last week was due to

the miners waiving the check-off and the operators granting an increase of one-half of the Cleveland scale. This means an increase ranging from 3c. to 5c. per ton, an increase in all other labor, and the two weeks' pay. Many of the operators had been willing for some time to give a small increase, providing the check-off was waived, but all efforts earlier in the contest failed because the miners were willing to concede everything as a compromise, providing the operators would agree to the check-off. The latter concession, however, the operators of the district absolutely refused to grant under any condition.

It is expected that before long, many of the cars that have been used in this section will be returned to the roads which loaned them, and that West Virginia will then again suffer through a lack of cars.

Birmingham, Ala.

The Birmingham coal market maintains a satisfactory firmness with bright prospects for the year. The most vital factor affecting the market during the week has been the advance in the wages granted a large percentage of the Alabama miners. The advance was 2½c. per ton, effective May 1, for all operations on what is known as the Pratt seam. Practically all mines were compelled to follow some of the leaders who agreed to make the advance.

Contracts for domestic coal which have been pretty well concluded for the year, were negotiated at a slightly better price than last year. In the Alabama market, domestic coal contracts are largely covered during April and steam contracts date from July 1.

The commercial coke plants are running full capacity in Alabama with a ready market at firm prices. The Alabama coke producers have not followed Pittsburg and Virginia in coke advances, for the reason that Alabama's general prices are higher than in Pennsylvania and Virginia and local labor conditions have not operated against production as in the more northern market. Standard 72-hour foundry coke is very firm at $2.25@2.50 per net ton at Alabama ovens, with retort grades quotable at from $2.75@2.85 per ton at ovens.

Nashville, Tenn.

The union operators in the west Kentucky field on the L. & N. R.R. and I. C. R.R. have not as yet effected a settlement and their mines are still idle. There have been many conferences held between the operators and miners in Louisville for the past six weeks. A meeting was held last week in which the operators delivered their final ultimatum and this is to be acted upon this week by a referendum vote of the miners in this district. It seems as though the principal contention has been to get a correct interpretation as to the meaning of the Cleveland agreement.

The nonunion mines in this field, located both on the I. & N. and I. C., have been supplying all the coal from this district. As the demand is light they have been able to do this very easily, and at the same time it has given them an unusually good tonnage for this season of the year. There is very little request for any coal except the finer grades, which are in great demand at high prices.

It looks as though better prices will prevail on contract coal for the coming year and a rather good season is looked forward to by the mining interests in this field.

Chicago

While coal dealers are not inclined to make predictions, it is regarded as certain that the present buying movement will absorb a very substantial amount of coal during May. It is expected this will increase in vigor during the latter part of the present month. At present the buying comes principally from the railroads, although there has been a certain amount of business coming from the users of steam coal who recently found themselves at the end of their resources. This enables the commercial mines to continue doing some business, but it is not expected these mines will have a big market until toward the end of May.

The coke market is active and spot business in furnace and foundry coke is fairly good at firm prices. The supply of Indiana and Illinois coal is not sufficient now to warrant any fixed market quotation.

Prevailing prices at Chicago are:

Sullivan County:	
Domestic lump	$2.62@2.87
Egg	2.50@2.75
Steam lump	2.17
Screenings	1.67@1.82
Springfield:	
Domestic lump	$2.57@2.82
Steam lump	2.17
Mine-run	1.97@2.07
Screenings	1.67@1.82
Clinton:	
Domestic lump	$2.52@2.77
Steam lump	2.17
Mine-run	1.97@2.07
Screenings	1.67@1.77
Pocahontas and New River:	
Mine-run	$3.15
Lump and egg	$3.30@3.55

Coke—Prices asked for coke are: Connellsville and Wise County, $4.75; byproduct, egg and stove, $4.55; byproduct, nut, $4.55; gashouse, $4.75.

Indianapolis

There is nothing particularly encouraging about the coal-mining industry in this state. Both operators and miners are greatly disappointed because the mines have not resumed work. The operators say that orders are piling up and the scarcity of coal in localities is becoming acute. Public institutions and manufacturing plants are borrowing coal of railroads fortunate enough to have some in storage.

When the joint conference of operators and miners meets again, it will be to hear a report from a policy committee composed of Kelsheimer and Stewart for the miners, and Hewitt and Gould for the operators. The operators, notwithstanding their desire to open the mines, seem determined to refuse to enter into negotiations until the men return to work, and the men are as determined to obtain some of their demands first. It is said that President Walker, of the Illinois United Mine Workers, has promised money to aid the Indiana miners during the prolonged deadlock.

Minneapolis—St. Paul

Coal trade in the Twin Cities and the Northwest is still very inactive, and the majority of coal men look for another month of quietness before business will be normal again. Prices have been received on Pocahontas Smokeless, Splint, Hocking and Youghiogheny Coals, and contracts are being let at 10c. per ton less than circular prices prevailing last year on all these coals. Contracting this year has not been quite as heavy as last, owing to the fact that the shipper has not known where he was at in the way of prices, but of late many contracts have been signed and it is rumored several of the larger ones have been made at a low price.

Franklin County and Harrisburg coal is being quoted at $2 and $2.10 on lump, egg and nut sizes at mines, screening from $1.10 to $1.30, and Carterville and Springfield district coals are quoted at from $1.75 to $2 for lump and egg, f.o.b. mines. The retail business is very quiet and will probably continue so.

St. Louis, Mo.

Mining has been partially resumed in Illinois, although on a very small scale. Mines in practically all the districts in southern Illinois are working, but in some sections there are but two or three that have started up.

There is absolutely no demand, and that produced is sometimes held at the mine for a couple of days until a market is found. It is evident from the prices quoted that several operators are not figuring the new insurance feature. The casualty companies are asking approximately $12 on each $100 of the payroll, as they claim it is impossible to do business under the recent Illinois law at a figure less than that.

There would be a good demand in St. Louis for anthracite, were it possible to get any, and smokeless is not as lively as it might be. The same applies to coke, both byproduct and gas house. There is nothing to indicate that the market will

pick up on any of the fuels in St. Louis in the immediate future, and it opened the earlier part of the present week, as follows:

Carterville	
6 in. lump and 3x6 egg	$1.50
2x3 nut	1.35
Screenings	1.00
Mine-run	1.10
Standard	
2 in. lump	$1.05
2 in. screenings	0.90
Mine-run	1.00
Nut	0.95

Portland, Ore.

While oil is being substituted for coal in a good many instances, it is also true that coal is taking the place of wood, particularly in sections where the forests have been thinned out. It is pointed out that could coal be obtained at a little less cost it would soon make a heavy inroad on the demand for wood fuel.

The coal trade in Portland is not very active at this time of year because spring is well advanced, but dealers report business this year about equal to the average for May. There has been no change in quotations here and it will probably be another month before storage prices are put into effect.

Receipts of coal are light in that the stocks are pretty full and it is not expected there will be any heavy shipments again until next fall.

San Francisco

For the past two or three weeks the local trade has been very quiet and the movement far from brisk. On the other hand, deliveries of domestic have been exceedingly meager, and as a consequence the stock on hand has not decreased.

The arrivals up to nearly the close of last month consisted of 4971 tons of Australian and 4593 tons of Wellington. The U. S. Government has received three cargoes of Pocahontas for the Navy, aggregating 16,683 tons, and the Pacific Coast Co., 4524 tons of steam coal from its Washington collieries, for use on the coast steamers.

The receipts of Rocky Mountain coal have been fairly good, considering prevailing conditions.

Prices to the trade are as follows per ton:

Wellington (British Columbia)	$8.00
Pelau Main (Australian)	8.00
Rocky Mountain	8.50
Anthracite (Lehigh)	15.00
Cumberland	12.50

Production and Transportation Statistics

The Car Situation

Increases in number of idle coal cars were most noticeable through the Middle Atlantic States and Middle West. In the Middle Atlantic territory the car surplus jumped from 22,500 to almost 50,000, and in the Middle West the increase during the fortnight exceeded 100 per cent. Both of these sections have on hand a comparatively large number of idle cars, although the present surplus of cars in the Middle West is not as large as the surplus at this time last year. In the Northwest there was about a normal number of freight cars idle. While the increase in the box-car surplus was not as marked as the gain in coal cars, it was by no means confined to any particular section of the country. There was a better demand for box cars in Montana, Wyoming, Nebraska, and on Canadian lines, but not sufficiently large to reduce the total surplus in those territories.

The following table shows the surplus and shortages of cars on 169 roads on Apr. 25 last:

	Surplus	Short	Net Surplus
Box	19,583	6,152	13,431
Flat	6,857	1,613	5,244
Coal, gond. and hopper	94,692	2,144	92,548
Other kinds	30,054	2,396	27,658
Total	151,186	12,305	138,881

Various Railroads, Rivers and Canals

The following is a comparative statement of the fuel movement over various railroads, rivers and canals for February, 1911-12[1]:

Railroads	1911	1912
Baltimore & Ohio[2]	2,187,226	3,397,088
Buffalo, Rochester & Pittsburg[3]	612,341	790,801
Buffalo & Susquehanna[3]	157,031	167,375
Chesapeake & Ohio[2 4]	1,530,710	1,337,216
Erie[4]	637,734	721,481
Huntingdon & Broadtop Mountain[2 3]	83,127	136,811
New York Central & Hudson River[3]	632,564	706,573
Norfolk & Western[2 3]	1,402,765	1,922,225
Pennsylvania (east of Pittsburg & Erie)[2 5]	4,646,198	6,217,396
Pittsburg & Lake Erie[2 5]	1,023,056	1,476,748
Pittsburg, Shawmut & Northern[3]	114,239	202,137
Southern[4]	358,917	451,081
Virginian[2 3]	162,343	294,041
Western Maryland	192,284	255,063
Rivers and Canals		
Canals and Falls at Louisville	239,173	18,050
Chesapeake & Delaware Canal	8,193	2,700
Davis Island Dam	448,160	101,245
Green River, Lock No. 1	2,202	1,356
Kanawha River	93,580	78,320
Kentucky River, Lock No. 1	6,100	4,600
Monongahela River	1,005,461	450,352

[1]Figures throughout this table have been reduced to a uniform basis of short tons

[2]Includes coal received from connecting lines.

[3]Includes company's coal.

[4]January figures.

[5]Does not include company's coal hauled free.

Foreign Markets

Russia

Bituminous-coal production of the Donetz district for 1911 was 16,607,600 tons, as compared with 14,013,390 tons for 1910 and 14,952,745 tons for 1909. Production of anthracite in 1911 was 2,903,870 tons, as compared with 2,398,000 tons in 1910 and 2,546,300 tons in 1909. The production of coke was 2,705,000 tons in 1910, as compared with 3,292,000 tons in 1911.

France

The imports of coal into France during the first two months of this year totaled 2,751,400 tons, as compared with 2,906,000 tons in the corresponding period of 1911. The imports of coke for the same period of 1912 were 388,900 tons, as compared with 446,200 tons in 1911, while the imports of briquettes were 204,300 tons, as against 207,000 in 1911. The exports of coal during the first two months of 1911 were 192,736 tons, as compared with 356,209 tons for the same period of the current year. Coke exports during this same period of the current year were 27,831 tons, as against 30,488 tons in 1911.

Austria-Hungary

During 1911, 10,872,928 tons of coal were imported into Austria-Hungary, as compared with 9,864,462 tons in 1910 and 10,482,264 tons in 1909. The imports of coke in 1911 totalled 702,707 tons, as compared with 670,089 tons in 1910, and 701,281 tons in 1909.

Exports of coal during 1911 were 609,737 tons, as compared with 615,082 tons in 1910, and 633,253 tons in 1909. Coke exports for 1911 were 299,915 tons, as compared with 230,735 tons in 1910, and 198,313 tons in 1909.

Financial Notes

The Lehigh Coal & Navigation Co. has listed $3,000,000 collateral trust 4½% gold power bonds, due Dec. 1, 1921, and $1,750,000 collateral trust 4½% gold bonds due Nov. 1, 1930, on the Philadelphia Stock Exchange.

Although comparatively speaking the Nova Scotia Steel & Coal Co.'s earnings are small, 8% has already been paid on the preferred stock, the issue amounting to $1,030,000. In 1909 a common stock dividend of $1,000,000 was distributed, which increased the total outstanding to $6,000,000.

It is estimated that the Pittsburg Coal Co. will benefit to the extent of $1,160,000 a year by the ruling of the Interstate Commerce Commission in reducing the freight rate to lake ports 10c. per ton, but this will be offset to some extent by the increase of 5c. a ton in wages to miners. The net advantage to the company, however, will be about $600,000 a year.

The Delaware & Hudson coal operations during 1911 included the mining of 7,280,939 tons of coal, an increase of 633,280 tons. Gross revenue from the coal mining department was $13,355,014, an increase of $1,548,126 over 1910; gross expenses amounted to $13,238,304, an increase of $1,790,077, leaving a net revenue for this department of $116,710, a decrease of $241,951 for the year. Construction and betterments included in the coal department expenses amounted to $823,654, as against $766,673 in 1910.

In the year to June 30 last, the Philadelphia & Reading Coal & Iron Co.'s income account wound up with a loss of $103,316. For 1910 the loss was $71,500 and for 1907, $71,482, an aggregate deficit for the three fiscal periods of $246,298. In 1909 and 1908 profits of $66,973 and $207,523, respectively, were shown, or $274,496 in total. Thus the net profits for the five years were $28,198. This only partially measures the unprofitableness of Reading's coal business, as the foregoing balances make no allowance for full interest on capital invested in coal lands.

Baldwin-Westinghouse Mine Locomotive

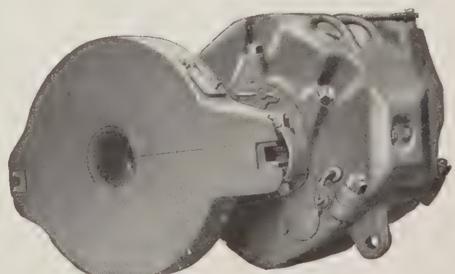
Apparatus that will successfully withstand severe service is produced by long practical experience.

Baldwin-Westinghouse Electric Mine Locomotives

are the products of the combined experience of the Baldwin Locomotive Works, for 80 years the foremost locomotive builders in America, and the Westinghouse Electric & Mfg. Company, the leader in the manufacture of electric haulage equipment ever since the beginning of electric traction.

This experience is embodied in the design of every detail in the construction of Baldwin-Westinghouse mine locomotives. Each part is known to be best adapted to the service it must perform.

In consequence, Baldwin-Westinghouse mine locomotives are, above all, reliable.



Westinghouse Mine Motor

They do their work steadily day in and day out, getting out maximum tonnage at the least expense and in the shortest time.

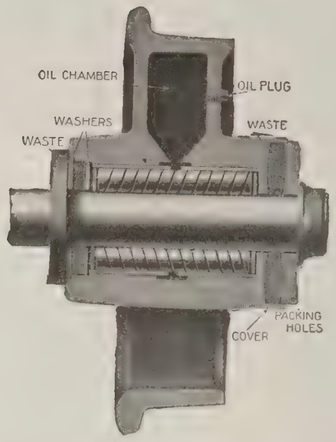
There is a Baldwin-Westinghouse locomotive for every class of service. The proper locomotive for your mine will be recommended by Westinghouse engineers after a careful study of conditions.

Address either Company—

The Baldwin Locomotive Works—Westinghouse Electric & Mfg. Co.

Philadelphia, Pa. **East Pittsburgh, Pa.**

As a Mine Operator Or Mine Superintendent,



are you interested in reducing cost per ton of material mined?

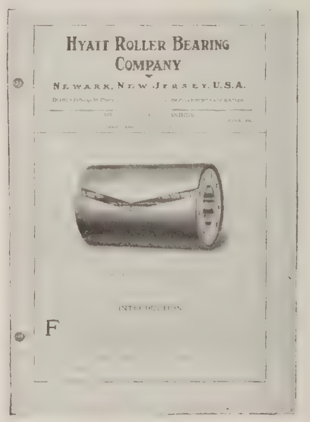
When the draw-bar pull of a loaded car is reduced 50 per cent—
When the percentage of fractured wheels is reduced to a minimum—
When the lubricating cost, including both oil and labor, is cut in half—
The cost of mining is greatly reduced, is it not?

All of these economies and others may be effected by adopting wheels equipped with

HYATT FLEXIBLE ROLLER BEARINGS

The Flexible Spiral Roller is an exclusive feature of Hyatt Bearings and this roller

Being Flexible, cushions shock;
Being Tubular, acts as an oil reservoir;
Being Spiral, with rollers alternated right and left it distributes the oil throughout the bearing and carries grit or foreign matter into the hollow of the roller, leaving the path of the rollers absolutely clean.



Hyatt Bearings may be obtained in twelve standard makes of mine car wheels. Write today for Bulletin No. 604D.

COAL AGE

Vol. 1 NEW YORK, MAY 18, 1912 No. 32

EVENTS of the past few weeks have proved that the foreigner at our coal mines is a factor to be reckoned with. If John White and his lieutenants can't control this hot-headed, lawless element in their organization, certainly no lasting good can ever result from even the slightest recognition of the Miner's Union.

Innocent people have been slaughtered, bad feeling engendered and public confidence in the power of labor leaders to negotiate a contract destroyed—all because an ignorant and excitable body of men have been herded into our anthracite collieries through the short-sighted economic policy of mine owners. The future of native labor has been seriously injured, and a soil adapted to the cultivation of radical socialism and anarchy has been provided.

In handling our most recent controversy, one or two anthracite managers acted unwisely in attempting to load coal with men drafted from their engineering department, but there was no sufficient and excusable reason for the riots that occurred when repair men were sent underground, and surely no one believes that an operator must allow his mine to flood when only a suspension is in force and a strike not yet ordered. The course of conduct followed by the American members of the Union has been admirable, and we begin to wonder whether in this matter of alien labor, the industry has not "sowed a wind from which it will reap a whirlwind."

In 1910, only 27 states exceeded in population the number of immigrants who came into this country. Up until 1880 these newcomers were mostly from the countries of Northwestern Europe. They were not dissimilar to our early colonists, were skilled artisans and were accustomed to a representative form of government. During the past 30 years, the tide of immigration has begun to flow from Southern Europe, bringing people trained under an autocratic government, and not far removed from serfdom.

In 1860, Germany, Great Britain and Ireland furnished 88 per cent. of the total immigration, while Austria-Hungary, Italy, Russia and Poland sent only four-tenths of one per cent. During the decade 1881–1890, the percentages were 55.6 and 17.6 respectively. Then the balance turned; industries were centralized and employers called for the unskilled peasants of Southern Europe. During the period 1891–1900, the percentages were 31.6 and 51; in 1909 the figures were 13 and 63 respectively.

Advocates of unrestricted immigration contend that large-scale industry requires a floating and unemployed labor force. It might be better, however, to dovetail industries so as to spread the demand more equally over the entire year. Irregular working habits demoralize labor. It is also a fact that wage-earners having a low standard of living delay the introduction of improved labor-saving machinery. Today we are more dependent upon the utilization of mechanical ingenuity than upon the presence of a mass of unskilled workers.

The immigrants who came to this country in 1909 brought with them $17,331,828, and more than one-half of them brought less than $50 apiece. During one year of ordinary prosperity the total amount of money sent abroad by foreigners is approximately $200,000,000. That ablest of labor leaders, John Mitchell, says: "The American people should not sacrifice the future of the working classes in order to improve the conditions of the inhabitants of Europe. Unregulated immigration is certain to degrade labor in this country."

The only way the native American has been able to rise has been by delaying marriage, and by reducing the average size of families. One authority goes so far as to claim that immigration has not increased the population, but merely replaced the native with foreign stock. Furthermore, unrestricted immigration aggravates cycles of overproduction, produces a sort of caste system, and generates political evils. It would be better to raise the standard of living in this country and let our influence spread by contact and example, rather than to try and lift all nations at once and only a little way.

Our mines can produce 50 per cent. more coal than we can consume or export, so why flood the market with alien labor that cannot be controlled by employer, nor led by fellow worker?

The New Buck Mountain Breaker

By E. L. Cole

A thoroughly modern anthracite plant of 1800 tons daily capacity is here described. The breaker embodies several new and important features of design, notably a belt conveyor for loading out all coal, and requires only 36 employees for its operation. The structure is of concrete and steel fireproof construction, thoroughly equipped, excellently lighted and practically free from dust.

The Lehigh Valley Coal Co. has just completed the construction and equipment of the surface plant for its new Buck Mountain colliery. This is located on top of the north spur of the Broad Mountain, 1642 ft. above sea level, two miles east of Mahanoy City, Penn.

The new plant has been erected for the purpose of handling the output which was previously prepared at the old Buck Mountain and Vulcan breakers, situated about three-quarters of a mile east and west respectively from the present operation, and these older structures have now been abandoned. The Buck Mountain, Seven Foot, Skidmore, Mammoth and Primrose seams are worked in this locality.

The plant, as a whole, is thoroughly modern and complete. It comprises a breaker, boiler house, shop, warehouse, office, etc., all of concrete and steel fireproof construction. The general layout of buildings and tracks is shown in the plan, Fig. 1. The feature of greatest interest, however, is the breaker. This is built beyond the outcrop of the underlying coal and adjacent to the tracks of the Lehigh Valley R.R.

Novel Departure in Breaker Design

The Buck Mountain breaker embodies a number of new and unusual features, notably the loading of all transportation cars, one at a time, by means of a belt conveyor, which serves a double row of storage pockets running at right angles to the loading track. In this respect, and in general design, it is similar to the Lehigh Valley company's Mineral Spring breaker near Wilkes Barre, Penn., which has been in successful operation for nearly a year. In construction, however, it differs from the Mineral Spring plant, in that the pockets and entire substructure, up to the level of the jig floor, are of reinforced concrete, instead of steel and timber, as in the previous design.

Some apprehension was felt by the designer in regard to the disintegrating action of acid water on the concrete of the storage pockets, and to adequately provide against such action, the bins were lined as follows: The concrete surfaces first having been coated with a special waterproof paint, a layer of 2-in. plank was laid down and covered with prepared roofing, and on top of this was placed a flooring of 1-in. boards. The whole was then covered with 1-in. hard wood to take the wear of the sliding coal.

Above the jig floor, the breaker framework is of structural steel, sheathed with corrugated iron. Timber is used to some extent for supporting machinery, in the construction of chutes, and in some instances for walk ways and stair treads. But taken as a whole, the structure is obviously non-inflammable and practically fireproof. Too much emphasis can scarcely be given to the desirable results obtained by the liberal provision of large steel-framed window sash. These afford ready means of ventilation, in addition to an abundance of light which is remarkable in comparison with the murky interior of the average breaker.

Method of Preparation is "Wet"

The method of preparation adopted at Buck Mountain is in some respects distinctly different from that usually employed. In the first place, it was not desired to make any size of coal larger than egg at this plant, and consequently the lump, steamboat and broken sizes, separated at the head to facilitate cleaning, are immediately broken down. Moreover, it was determined that the most dependable results could be obtained by submitting the entire output (excepting the smaller steam sizes) to a jigging process, and this results in a system of preparation which is consistently "wet" throughout.

Coal is hauled to the breaker in mine cars by two Vulcan Iron Works steam locomotives from the Vulcan and Buck Mountain slopes, located, as previously mentioned, about three-quarters of a mile east and west respectively from the new operation. The cars enter the double tracks, under the extreme northern side of the breaker, which is partitioned off from the rest of the building by a wall of vitrified tile. This serves the dual purpose of a fire wall, and an inclosure for the under part of the breaker structure.

The coal cars are hoisted to the top of the breaker, a distance of 162½ ft. on single-deck self-dumping cages, operating in a double-compartment steel tower. During a recent trial run, 22 cars were hoisted and dumped in 16 min. The coal empties from the mine cars into a dump chute or hopper and is fed, under control of hand-operated gates, onto a pair of 4x16 ft. double-deck shakers.

Picking Done at Head of Breaker

Steamboat and lump sizes are taken off the top deck of these shakers and led to a moving picking table, 5 ft. wide and 28 ft. long, which is centrally located on the headroom floor. Stationary platforms about 6 ft. wide are built up flush with the moving table on each side, and the four pickers who are stationed here to examine the coal (two each on the right and left) work in pockets about 2 ft. deep. This arrangement enables the men to slide the coal or rock from the moving band without any lifting, thus lightening their task and increasing the efficiency of their labor. At the center of table, the headroom floor slopes up from either side to provide alleyways for the removal of particularly large pieces of rock. Doubtful coal is pushed by the pickers to the right and left of the moving table, and the slate is here chipped off by four men and thrown into the rock chute. A clutch lever, near the end

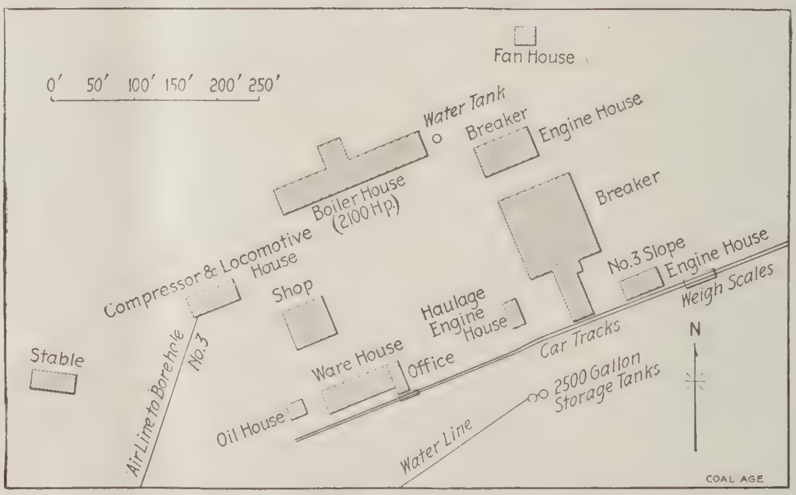

Fig. 1. Layout of Colliery Buildings and Railroad Tracks

of the picking table, affords a ready means of stopping it when desired.

A diagram indicating the flow of coal through the breaker is shown in Fig. 2. When the steamboat and lump coal leaves the picking table, it enters a set of compound-geared crushing rolls, which have a peripheral speed of 300 ft. per min. These rolls are of the segment

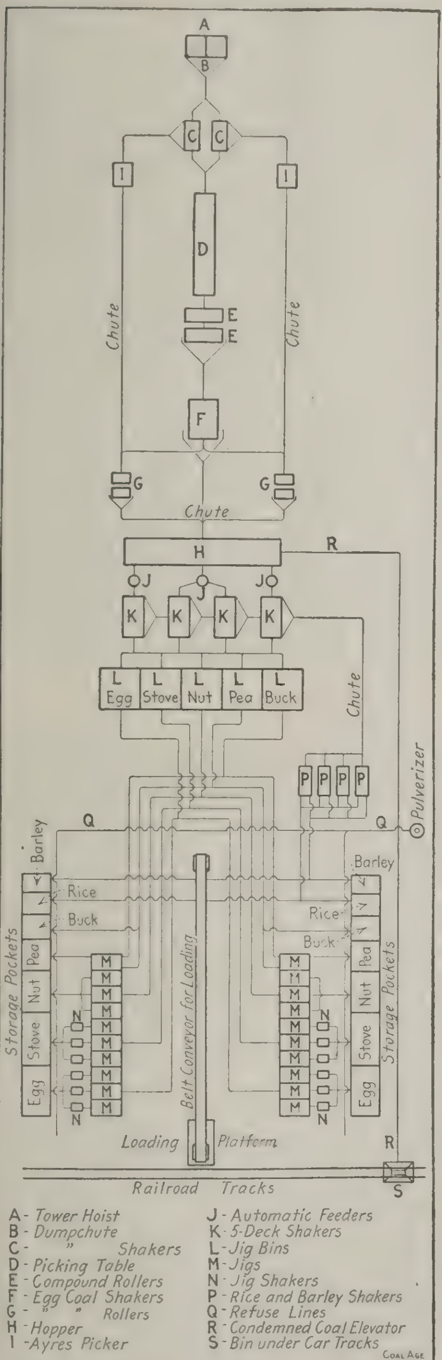

Fig. 2. Diagram Showing Run of Coal

type, affording a convenient means for changing their size and facilitating repair work when needed.

From the crusher rolls, the coal drops through a waterfall chute, a distance of 12 ft., to a single deck shaker, which takes off coal of egg size. This may be led directly to the pocket *H* or sent to the No. 3 rolls and broken down. The under size from the above mentioned shaker and the broken-down egg go to the hopper *H*.

Breaker Automatically Fed from a Large Receiving Hopper

The broken coal, which is made over the lower deck of the dump-chute shakers, passes to a pair of Ayres pickers and then enters the No. 3 rolls. All coal smaller than broken drops into the hopper *H*. There is thus collected in the hopper, all the coal which passes through the breaker and when it reaches the hopper it is all of egg size or smaller.

From the hopper, the coal is fed out through three Tench automatic feeders to four banks of shakers of the five-deck Parrish type, which separate it into egg, stove, chestnut, pea and buckwheat sizes. Coal of each size is then conducted through water-fall chutes to its proper 30-ton pocket, five of which are located immediately above and behind the jigs. The jigs are of the standard Lehigh Valley type and are 20 in number, 10 on each side of the breaker, and, as to service, are divided as follows: 5 egg, 5 stove, 6 chestnut, 2 pea and 2 buckwheat. The pea and buckwheat jigs are interchangeable, so that four jigs are available for either size.

All coal screened through the buckwheat shakers passes to four sets of rice and barley shakers, having $\frac{3}{16}$-in. and $\frac{3}{32}$-in. round mesh on the upper and lower decks respectively. Coal passing through the $\frac{3}{32}$-in. mesh goes out with the wash water, which is used for flushing ashes from the boiler house.

From the egg, stove and nut jigs, the coal is discharged by the individual jig scraper lines onto small shaking screens, which remove any undersize material that may have resulted from breakage in the chutes and jigs. It then passes to the pockets after examination by pickers stationed on the jig floor. The jig refuse is carried away by two scraper lines, one in front of each battery of 10 jigs, and is conveyed to the rock chute. Rock from all parts of the breaker is collected in this chute and led to a No. 6 Gates crusher, furnished by the Allis-Chalmers Co., Milwaukee. After passing through the crusher, the rock is conveyed, at the present time, by a scraper line, about 125 ft. to a rock dump on the mountain side.

The jig tanks are flushed out by means of hand-operated gates, which discharge into concrete hoppers and troughs under the jigs. This slush is carried over a shaking screen, and the material screened out is returned to the breaker by way of a scraper line, which discharges into the condemned-coal elevators.

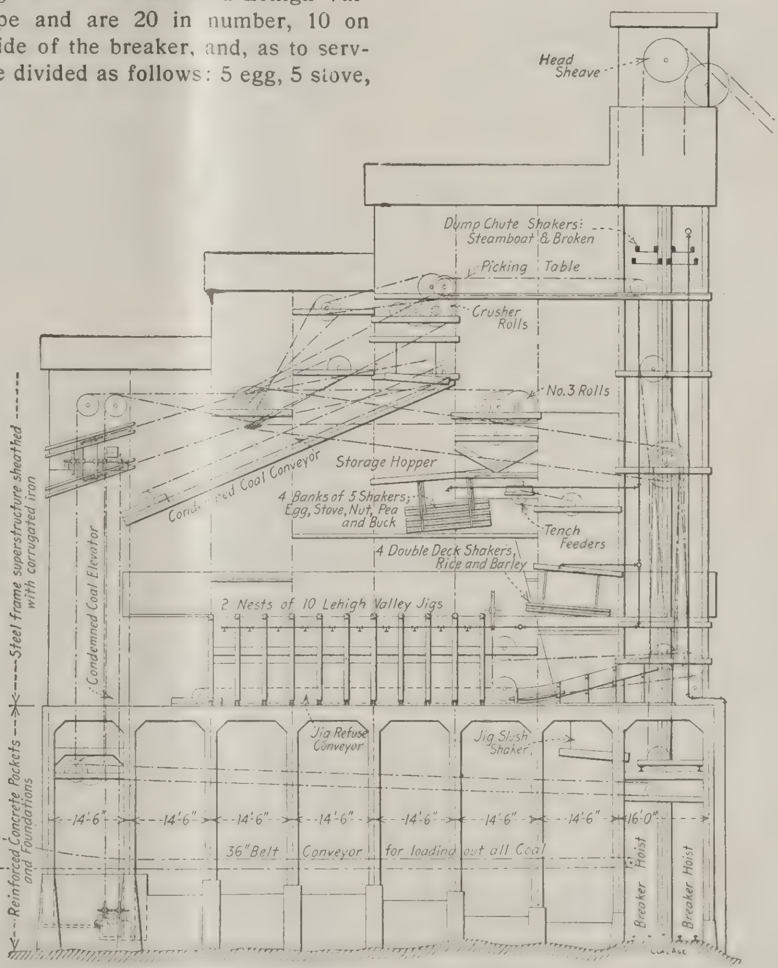

Fig. 3. Side Elevation, Buck Mountain Breaker

Cars Loaded by Belt Conveyor

A view of the loading headroom, looking down on the 36-in. conveyor belt and operator's platform is shown in Fig. 5. This

conveyor belt runs centrally between the two rows of storage pockets, which are in duplicate, so that every size of coal is stored symmetrically on both sides of the belt. Coal is led to the belt by curved chutes, which deliver it longitudinally in line with the direction in which the belt moves. Its flow from the pockets is regulated by a number of pivoted lift gates, all of which are operated from the loading head through a system of shafting and levers, under the control of the one man employed there.

The belt conveyor is provided with a steam-operated boom end for adjustment to suit the several sizes of railroad cars, so that unnecessary breakage is avoided. All this mechanism, the belt itself, pocket gates and the boom end, is run and controlled by one man, who is thus enabled to load seven cars an hour without other assistance than a man outside to drop the cars into place. It will be noted from Fig. 5, that the operator's position at the head of the loading platform is inclosed by large windows, which protect him from inclement weather and at the same time afford an unobstructed view up and down the tracks.

To provide for the economical handling of condemned coal, hoppers are built under the railroad tracks, a short distance below the breaker, and cars which fail to pass inspection are brought here and dumped. The coal passes from the hoppers to a slightly inclined scraper line that carries it to the elevators *R*, in the front of the breaker, whence it travels to the hopper *H*, or No. 3 rolls, as the case may be, for repreparation. It will be noted that there is but one set of elevators in the breaker. This handles all screenings, pickings and material from the jig-slush shakers as a usual load, but is of ample capacity to take care of the condemned coal in addition, and this latter material is thus prepared at a minimum of expense, since no additional labor is involved, except possibly one man to handle the railroad cars.

Railroad Cars Handled by Continuous Cable Haulage

Transportation cars are handled to and from the breaker by a continuous cable haulage, which is driven by a Litchfield compound-geared endless-rope haulage engine. This cable runs up and down throughout the length of both empty and loaded storage yards, and is so arranged that a car on any track may be moved by it in either direction. The cars are attached to the rope by a Morgan patent cable grip, carrying a 25-ft. length of chain for hooking on to some handy part of the car. The tracks throughout have a grade of about one-fourth of 1 per cent. in favor of the loads. This method of handling cars eliminates the delays consequent upon dropping them down by gravity in severe winter weather and enables one man to keep the plant supplied.

The breaker is driven by two separate engines, a 12 and 16 x 24-in. tandem-compound Corliss jig engine and an 18 and 36 x 30-in. cross-compound Corliss engine for the main drive, both built by the Vulcan Iron Works, Wilkes-Barre, Penn. Rope and belt transmission systems are employed, there being about 1670 ft. of belting, as compared with 3500 ft. of 1½-in. manilla rope.

There is in this building a noticeable absence of the vibration usually encountered in breaker structures, due in great measure to the fact that all shaking screens are balanced. An item worthy of special mention is the careful manner in which all bearings are housed, each being provided with a Philadelphia automatic grease cup.

A notable feature of the electric signal system in the breaker is the construction of the push buttons. These are made of two pieces of No. 12 sheet brass, mounted on oak blocks. The top plate, when bent down, affords a considerable rubbing surface on the under plate and a reliable contact is readily secured. The ordinary type of push button has failed to meet

Fig. 4. Ayres Picker for Broken Coal, and Shaking Screens

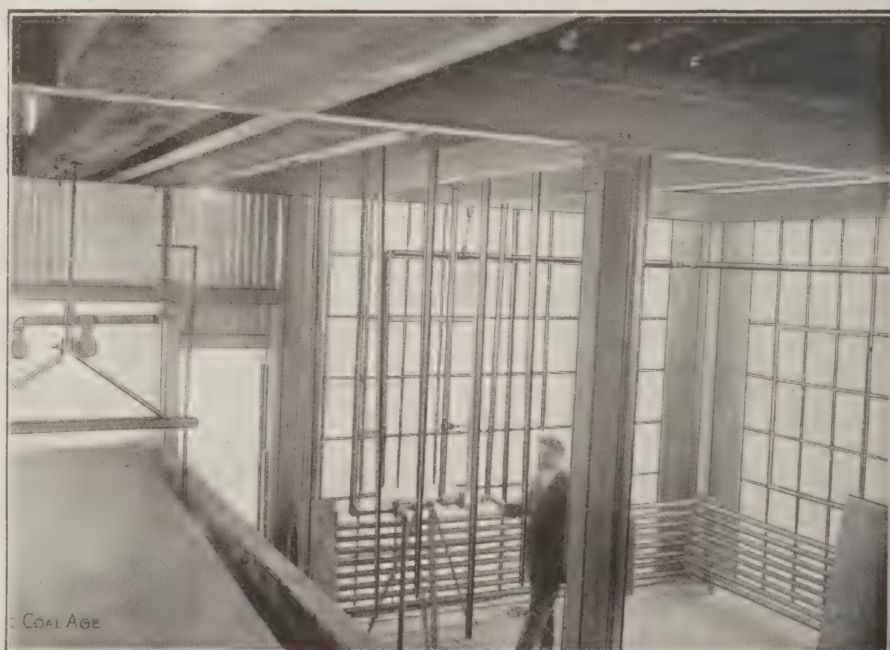

Fig. 5. Loading Conveyor and Operator's Platform, Showing Control Levers

the rigid requirements of breaker service, and hence this more rugged form has been devised. The breaker is electrically lighted when required, and is heated by exhaust steam, 15,000 ft. of 1½-in. pipe having been installed for this purpose. "Childs" fire extinguishers are located at convenient points throughout the building,

Fig. 6. Breaker Head Room, Showing Moving Picking Table

Fig. 7. Jig-room Floor, Showing Chutes from Jigs to Pockets

although the fire hazard has been reduced to a minimum by the elimination, as far as practicable, of inflammable material.

Conveniences for Employees

The space beneath the coal pockets is divided into two large rooms, closed on all sides by walls of hollow tile, plastered with cement mortar. The west room will be utilized for the storage of such heavy repair parts of the breaker machinery as will be kept on hand. The east room is being fitted up with toilet, etc., for the accommodation of employees. The floors are of concrete, and when completed, the facilities here provided will compare favorably with those of most modern factories.

The Buck Mountain breaker is designed to prepare 1500 to 1800 tons of coal per day, with a force of 36 employees, who are paid the usual wages for this class of work. That a very high degree of efficiency in operation has been attained is evident from this fact, and from an inspection of the working of the plant. Effective measures have been taken to reduce to a minimum the breakage of coal in its progress through the breaker. Every precaution has been taken to insure the safety of employees and to increase the efficiency of their labor, as, for instance, by providing abundant light, easy and convenient means of access to machinery and stairways of reasonable pitch. Perhaps the most comprehensive criticism that can be made of the plant as a whole is that it everywhere gives evidence of having been thoroughly and carefully planned, taking advantage of the best features of modern construction, applicable to this kind of work. The design radically departs in many particulars from the beaten path of breaker construction and marks a big advance in attaining greater efficiency and economy of operation.

The plant was designed by Paul Sterling, mechanical engineer, Lehigh Valley Coal Co., under the general direction of S. D. Warriner, vice-president and general manager, and I wish to express to Mr. Underwood, division superintendent, under whose supervision the colliery-construction work was carried on, my appreciation of the information and courtesies extended.

In our next issue will appear an article dealing with the loading conveyor, car-haulage system and some details of the breaker construction, together with a description of the steam-generating plant and engine equipment.

New Base Map of Illinois

A new map of the state of Illinois, on a scale of approximately eight miles to the inch, is ready for distribution by the State Geological Survey. It is prepared in three colors so as to represent drainage features in blue; railroads, land lines, towns, etc., in black; and county boundaries and figures showing altitudes above sea level for various towns in red. This map eliminates the errors of early land surveys, so that places are now shown with correct latitude and longitude. Railroad alignments are all highly accurate.

A copy of this map on heavy paper will be sent on receipt of 10c. in stamps to cover cost of mailing. A similar copy mounted on cloth and sticks will be sent if in addition to 14c. postage, a money order for 30c. is inclosed, payable to Fred Mees Bindery, of Chicago. Remittance should be sent to the Director of the State Geological Survey, Urbana, Ill.

The best and most economical form of gangway timbering is without doubt the three-piece all-steel form of support, as the steel legs cannot be split or crushed and are in the end more economical than wooden sets. Simplicity and economy have their highest development in this system of timbering.

Mining the No. 8 Seam in Ohio

By William Hibbs *

An interesting description of the No. 8 Seam roof conditions in Ohio, and some notes on the best method of controlling same. A heavy overlying stratum of fire-clay occurs and is difficult to handle. The poor top has caused enormous losses of coal.

The No. 8 coal sea.n is considered one of the most important in the country. It is better known to the mining profession as the Pittsburg seam. The underlying stratum is, in many places, composed of hard limestone, although a soft seam of clay is often found immediately beneath the coal, varying from a few inches to a foot in thickness. This forms a good floor upon which to work, though a difficult one in which to cut drains, as is often desirable.

Roof Conditions

Near the top of the seam is usually found a stratum of clay, varying from a few inches to 3 ft. in thickness. Above this is the roof coal, which, like the other parts, is irregular, and varies from an inch to several feet in thickness. When this latter is thin, the roof is usually poor, and when it is thick, a foot or more, the roof is good or favorable to any system of propping, as it forms a bond for the capping, which is placed on top of the timbers.

Above this roof coal is found a great obstacle to economic mining, especially in eastern Ohio. This is a stratum of clay and limestone, mixed irregularly, and sometimes stratified to some extent, with slate; it is from 3 to 20 ft. in thickness. Taken as a whole, it is soft and brittle, and when too small pillars are left, or the pressure becomes great, it is very difficult to hold, and often comes down without warning, especially where the roof coal has fallen.

This one difficulty, in connection with mining the Pittsburg seam in this state, has taxed the ingenuity of every mining official, and calls for the best judgment and experience to successfully handle. Many have succeeded fairly well, but others have failed, and not a few companies have gone to the wall on that account. Many of these difficulties have been overcome, but there still remain some errors in practice and customs, which are seemingly overlooked.

Mistakes in Timbering

In the accompanying line cuts, Fig. 1 shows a geological section of the strata in the vicinity of, and including No. 8 seam, while Fig. 2 is a sketch showing a cross-section of a working chamber or room. On the map, in Fig. 3, is shown a proposed plan for future mining of a section of a mine, consisting of a pair of butt entries. This is done sometimes by the engineer, but more frequently by the superintendent in the office, and Fig. 4 shows how it not infrequently works out.

Referring to Fig. 2, it will be noted that the main seam has been worked out, and that the thin seam of clay, sometimes called the head-stone, has also been taken down. The roof of coal has, owing to its spongy nature, sprung down and left a thin opening between it and the overlying clay at *F*, thus removing the support for the latter.

A portion of this material will soon slip out and rest on the coal beneath. Its opening will make way for more, and it will not be long until enough has fallen to overload the roof coal. It will then crack open at *A* and throw off chips at *C* and will be considered dangerous. By setting two props against the roof, it will hold until the load on the coal becomes heavy enough to break the posts or shear the coal around the caps, when the whole mass will fall.

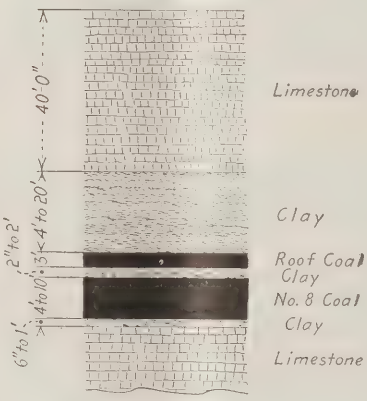

Fig. 1

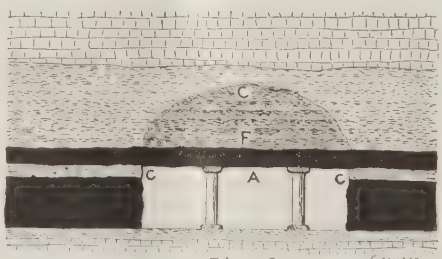

Fig. 2

No. 8 Seam Roof Conditions

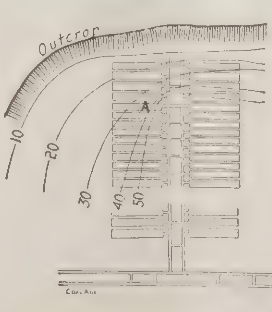

Fig. 3

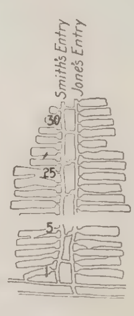

Fig. 4

*Mining engineer, Scio, Ohio.

The error in this case lies in not setting posts hard up against the roof, thus preventing the roof coal from springing away from the clay. Probably nine falls out of every ten in the No. 8 coal in Ohio are due to this cause, and I have seen as many as 20 per cent. of the posts set in a room, which were serving no purpose whatever. They were not carrying any load, and as soon as the roof settled, the capping would roll and displace the post instead of carrying the weight.

Proposed Plan and Actual Plan

In Fig. 3, the superintendent's plan looks splendid on paper, but he did not make any allowance in the pillars for a difference of weight, due to more or less cover. His rooms are just as wide and his pillars just as heavy under 20 ft. of cover as they are under twice that much. Also the entries were not driven by sights, and as a consequence are very crooked. As soon as the miners made a turn, they knew not which way to go, nor how far. The rooms were marked off by measuring along the crooked entries, and consequently are not evenly spaced, which resulted in thin ribs at some points and thick ones at others. The room necks widen gradually into full room width, instead of in the square way, shown on the plan, Fig. 3. As a result, there is always a place in the neck where it is so narrow that the miner thinks it not worth while to set posts, yet it is too wide to stand long alone, and the results before described are repeated. Two out of every five of the room necks on these entries broke down and gave trouble before the work was finished.

The rooms, like the entries, were driven without sights, and probably by sound through the ribs and an occasional crosscut. Often too many crosscuts were driven, some of them accidentally, and very frequently the law was violated as to the distance between them. The Nos. 1 and 2 rooms on both entries should never have been driven, as they rob the entry pillar.

Losses of Coal

On Smith's entry, all of the rooms were driven near a line, but owing to poor timbering and shutdown of the mine, the roof caved at the faces, and the management would not go to the expense of recovering them. The balance of the coal beyond their faces was left for future generations. On the same entry, rooms 24 and 25 were driven together when in

about half their distance. They were timbered at this place, but the roof broke down before the rooms were finished, and this was repeated several times in these entries.

These entries were driven just fast enough to make room for new working places as they were needed, and so proceeded slowly. By the time the last rooms were reached, all of the entry roof in both entries up to the third crosscut from the face was broken down to a height of 8 ft. above the coal. This roof material had all been removed from the mine. The last rooms on Smith's entry were abandoned, before reaching the limit, because it did not pay to send a mule and driver there to haul the coal out for only a few men. Thus the remainder of the coal was left, and practically lost to this and succeeding generations. On account of the roof breaking down in the entries and room necks, square with the coal, it was too dangerous to mine many of the ribs and entry pillars, and they, too, were left in.

Owing to this haphazard way of mining, only about 60 per cent. of all the coal was recovered. This is a common sight in many of our mines but improvements are being made. Many are driving their entries to the limit, timbering as they go, and by turning rooms at the back end first and bringing everything minable with them on the return, are meeting with much better success.

An Interesting Overwind Preventer

Special Correspondence

A new device for preventing overhoists is especially interesting if it has been proved effective and reliable. The arrangement here described possesses the virtue of leaving the engine entirely under control of the operator except when an overwind is imminent, and tends to insure careful running by registering mistakes.

The question of preventing overwinds, both in connection with vertical shafts and inclined haulages, is a matter which deserves the careful and constant attention of mine operators. The disastrous effects of an overwind are too well known to require emphasis, and inasmuch as even the most careful and skillful engineers are liable to lapses of attention and judgment, it is advisable to supplement human control by some form of mechanical protection. From time to time, numerous devices have been proposed for this purpose, each being more or less peculiarly adapted to the special conditions for which it has been devised, and it would be unfair as well as difficult to designate any one type as universally better or worse than others which have met with extensive application.

One of the most recent types of overwind preventers is shown in Fig. 1. It consists essentially of a screw, traveling nuts, and adjustable clutch points. By referring to Fig. 1, the nuts will be seen at some distance from either end of the screw, this position, of course, corresponding to that of the cage somewhere near midway in the shaft. The screw is driven by bevel gearing from some suitable part of the engine. In the case of a shaft hoisting engine, for instance, an extension of the governor driving shaft may be used. The gear ratio is such that the speed of the screw is increased to a sufficient extent to give quick and accurate operation. This speed is, of course, determined by that of the main engine, and the length of the screw is in proportion to the length of the hoist through which the cage travels.

Nut Traveling on a Threaded Shaft Represent the Cages

From the illustrations Figs. 1 and 2, it will be seen that the traveling nuts each have a gland *D*, made in halves and furnished with a pin which may be fitted into any of the holes around the periphery of the nut. These glands are so shaped that one side of the joint forms a jaw which engages and slides on a guide bar *E*. The nuts are thus prevented from rotating, and hence are made to travel along the screw from end to end. At each end of the screw, are mounted the clutch points *CC*. The nuts come into contact with either set of these clutch points according to the direction in which the engine has been rotating. It will also be noted that on each of the nuts *B*, there is provided a tripper *F*, which revolves freely around the nut. This tripper has points *G* which engage with the clutch points *C*, mentioned above, should the cage which is represented by a particular nut reach a predetermined point above the landing

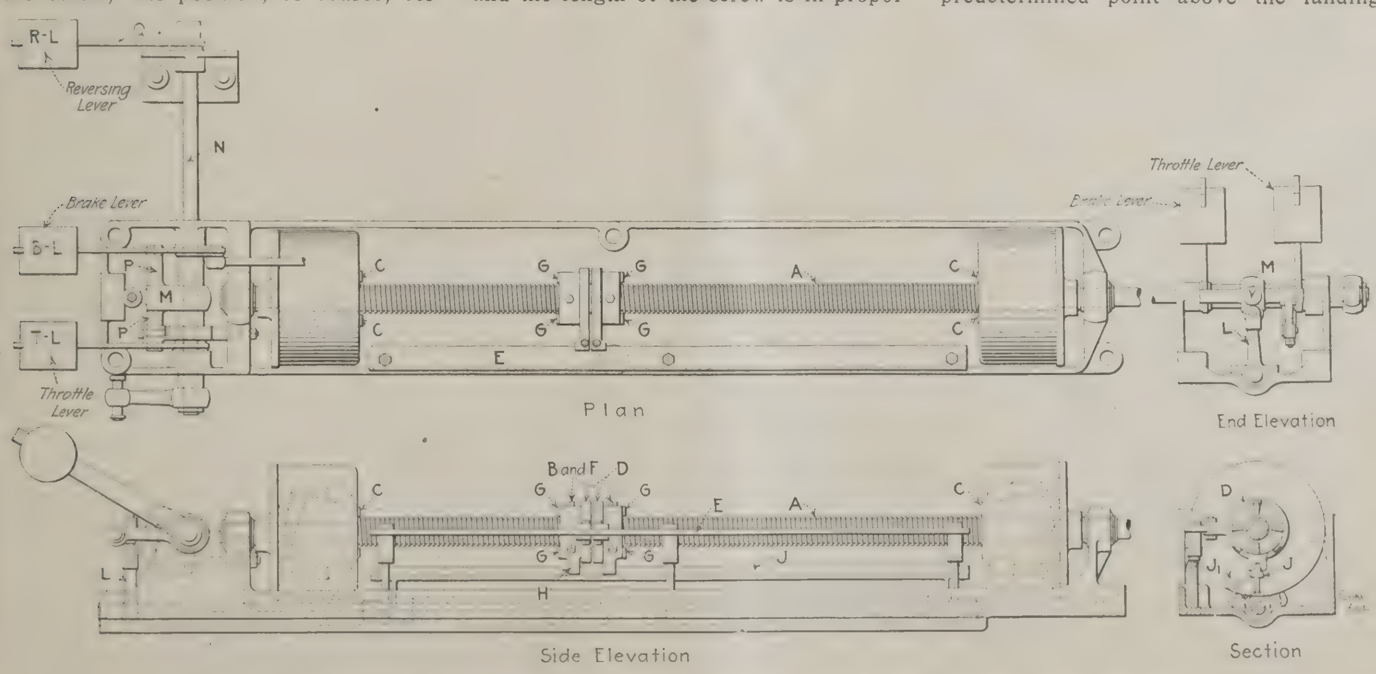

Fig. 1. Device for Preventing Overhoists, Showing Means of Control over Engine

position; or, should the speed be excessive in approaching the end of the wind, contact is made a few revolutions before the landing point is reached.

The way in which this is done will be seen by reference to Fig. 1. The tripper F has two teeth H, engaging the single tooth mounted on the trip lever J, this lever being of just sufficient length so that the teeth are engaged with it during the whole of the wind. The trip lever is secured to the shaft which also carries the supporting lever L. As long as this latter is perpendicular it prevents the lever M from leaving the horizontal position. The lever M is secured to the shaft N and so is the lever carrying the weights RL. The two levers carrying the weights BL and TL are, however, loose on the shaft, and are supported by the arms P until the tripping is effected. Fig. 2 shows an enlarged sectional view of the tripper nuts and the screw, giving a clearer idea of the construction.

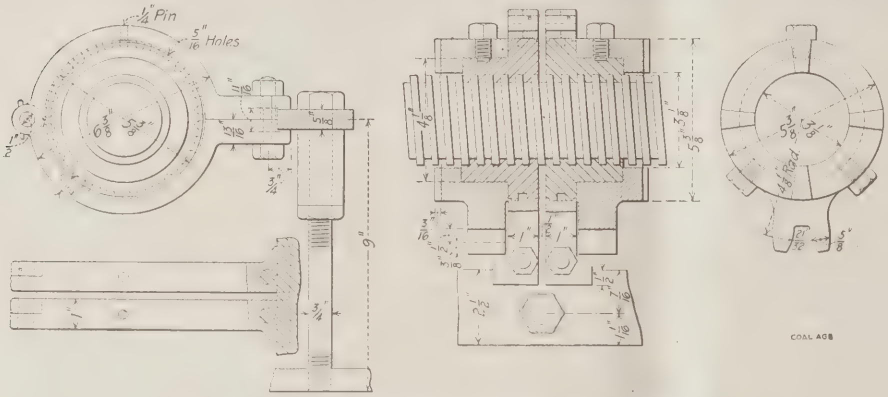

Fig. 2. Details of Traveling Nut and Guide

Purpose of the Governor

Turning now to Fig. 3, which illustrates the arrangement of the governor, it is seen that the purpose of this device is obviously to bring the engine to rest at a time when, owing to some mishap, the engineer has lost control of it. This is effected by advancing the clutch points from the position P to P_1. The two centrifugal weights B are mounted on the head casting C by means of pivoted bell-crank arms, which enter slots in the sleeve portion of the casting C and there engage the sliding shafts of the clutch points. As the weights fly out the clutch points are correspondingly advanced from P to P_1. A spring E is fitted behind the bell crank levers at the pivot points A, in order to prevent the weights from flying out too quickly at the beginning of the wind.

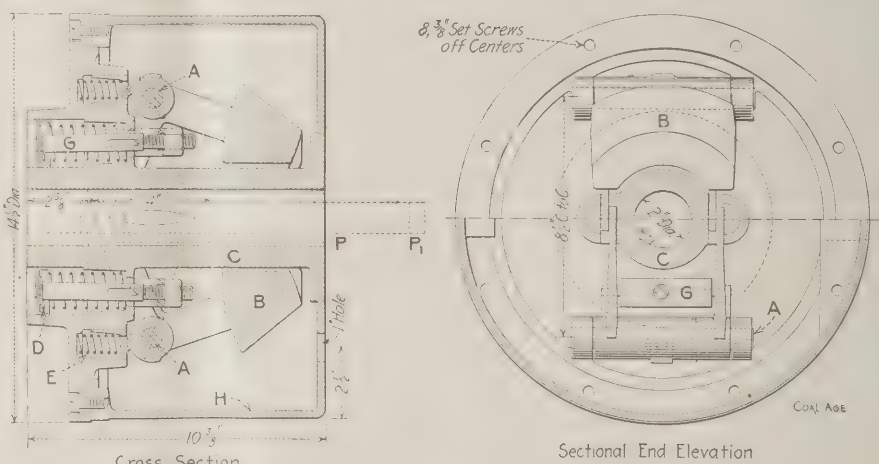

Fig. 3. Details of Governing Mechanism

Examination of the drawing wil. show that these springs are so placed as to become neutral when the governor weights are in their "out" position with the engine running, and only the tension springs D are left to restore the balls to the "in" position, when the engine is approaching the end of its wind. In addition there are two tension springs fitted between the weights for the purpose of securing better adjustment, and also to aid in bringing the weights back to normal position as the engine comes to rest. It will therefore be seen that the governor provides the automatic means previously referred to, of arresting the motion of the cage a little way below its landing position, should its speed at the time be too high.

Reliability and Accuracy

This governing device is securely incased and, if necessary, may be sealed in order to prevent interference. It has been found that in practice its sensitiveness, and at the same time its reliability are so great that the apparatus can be regulated to operate within an inch of the actual cage travel in either direction by means of the nuts, sleeve and pin, referred to above. If for any reason a release is effected, the engineman cannot put the apparatus again into normal position without help from someone else, and this means that he is made particularly careful in preventing such overwinds, as every time he makes a mistake publicity is given to the matter. If a further check is required, it is also possible to put a recording apparatus on the gear which will automatically register without the possibility of controversy every time the engineman makes a careless wind.

One of these gears has been installed recently at the Valley Field Colliery of the Fife Coal Co., Ltd., one of the largest colliery organizations in Scotland, in connection with a pair of Corliss engines having cylinders 36 in. in diameter and a 6 ft. stroke, with a working pressure of 150 lb. The drum is of the parallel type, 18 ft. in diameter, and fitted with double post brakes, while the ratio adopted for the bevel gearing driving the overwind preventor is three to one, an extension of the governor driving shaft being utilized. In operation, the plant has given considerable satisfaction and this method of automatically preventing overhoists, owing to its simplicity, comparative economy in first cost, and value in providing effective protection is worthy of the consideration of mining engineers in all parts of the world. This device is the outcome of considerable work and numerous experiments on the part of Mr. Landale, head of the firm of Douglas & Grant, Kircaldy, Scotland.

Gold Bearing Coal at Cambria, Wyo.

In explanation of the occurrence of gold in the Cambria, Wyo., coals, as noted in Coal Age, Vol. 1, p. 766, we quote the following excerpt from a recent U. S. Geological Survey Press Bulletin:

> An interesting feature about the coal mined at Cambria, Wyo., is that it is claimed to be gold bearing. Some of the coal has contained as much as $2 per ton in gold, and the coal was sold for only $1.50 per ton. When coke made at Cambria was selling for $3.50 per ton samples were taken from 31 cars during a period of three weeks and assayed. The samples showed an average of $2.46 per ton in gold and 28c. in silver. The explanation offered for the presence of gold in this coal is that the sands which submerged the old peat bog and now form the roof of the coal bed were derived in part from gold-bearing alluvium. While the sand was being deposited the gold worked down into the underlying bog and is now found in the coal.

Mining Coal on the Virginian Railroad

By Floyd W. Parsons

A new field containing more than twenty billion tons of high-grade minable coal has been opened. The chief markets in the immediate future will be New England and South America. Consolidation necessary. Low mining cost possible.

The richest coal field in the world is that territory situated in the southern part of West Virginia. The fuel here mined runs from 14,800 to 15,300 B.t.u., which heat value is not excelled by any variety of anthracite or bituminous coal in any country. Because of their excellent quality, these West Virginia beds, although located somewhat distant from important markets, have been rapidly developed. The extreme southern part of the field is reached by the Norfolk & Western Ry., while the upper edge of the district is touched by the Chesapeake & Ohio Ry. Both of these roads haul a considerable tonnage of the coal to tidewater, and a smaller tonnage to Western interior points.

Since the two roads above mentioned traversed the field on lines approximately 40 miles apart, there remained a large area of undeveloped coal that even branch lines from these main roads could not reach for many years to come. This situation was brought to the attention of Henry H. Rogers, and, in 1907, construction of the Virginian R.R. was commenced.

The initial aim of Mr. Rogers was to furnish a satisfactory outlet for that coal acreage in the Kanawha and New River basins, lying between the two older roads and not yet touched by them. The average haul from the coal field to the terminal at Sewalls Point, Va., is 410 miles.

Note—Substance of an informal talk before Eastern Bankers on an inspection trip over the Virginian Railroad.

Winding Gulf Coal Company Tipple, Store and Power House

The principal coal measures reached by the Virginian R.R. are as follows:

Series	Subdivision	Group	Seam
Allegheny		No. 5 block coal	Usually but one commercial bed.
Pottsville	Upper Pottsville or Kanawha	Upper Kanawha (splint coal)	Lewiston
			Coalburg
			Winifrede
		Lower Kanawha (softer coals)	Cedar Grove
			No. 2 gas
			Powellton
			No. 1 gas
	Middle Pottsville	New River group	Sewell seam Beckley
			Fire Creek
	Lower Pottsville	Pocahontas group	Pocahontas No. 6
			Pocahontas No. 4
			Pocahontas No. 3

The No. 5 Block Coal

The No. 5 Block coal is a good steam and domestic fuel. Its low sulphur content gives it freedom from clinker. In composition it is hard and stands transportation well. Its thickness ranges from 4 ft. to 20 ft., attaining the latter enormous size over a limited area near Bald Knob in Boone County. In physical structure it is between a typical splint and the ordinary type of hard bituminous coal, and stands transportation well. Following is an average of six analyses:

ANALYSIS OF NO. 5 BLOCK COAL

	Per Cent.
Moisture	1.81
Volatile matter	33.17
Fixed carbon	57.56
Ash	7.46
Total	100.00
Sulphur	0.79
Phosphorus	0.008
B.t.u.	13,581

Kanawha Group

The Upper Kanawha coals are hard and split into oblong blocks, having much the appearance of cannel coal. The three beds vary in thickness from 3 to 12 ft.

AVERAGE ANALYSIS OF UPPER KANAWHA COALS

	Per Cent.
Moisture	2.06
Volatile matter	33.99
Fixed carbon	57.59
Ash	6.36
Total	100.00
Sulphur	0.85
Phosphorus	0.006
B.t.u.	13,672

Lower Kanawha Coals

Separated from the Upper Kanawha beds by about 250 ft. of strata are the Lower Kanawha coals. These seams are softer than the beds above and are chiefly celebrated as gas coals. They are excellent for coking purposes, having the essential columnar structure.

AVERAGE ANALYSIS OF LOWER KANAWHA COALS

	Per Cent.
Moisture	1.39
Volatile matter	32.88
Fixed carbon	60.56
Ash	5.17
Total	100.00
Sulphur	0.95
Phosphorus	0.007
B.t.u.	14,405

nous Welsh coal used by the navy and so often compared to the New River product is as follows:

ANALYSIS OF RHONDDA VALLEY, GLAMORGANSHIRE COAL

(Authority, R. H. S. Redmayne, H. M. Chief Inspector)

Moisture	1.24
Volatile matter	18.53
Fixed carbon	77.19
Ash	3.04
Total	100.00
B.t.u.	14,159

The Welsh anthracite runs about 94 per cent. fixed carbon, with only 4 per cent. volatile matter and less than 2 per cent. moisture and ash. An average ultimate analysis of 37 samples of Welsh coal gave:

AVERAGE OF 37 SAMPLES

Carbon	83.78
Hydrogen	4.75
Nitrogen	0.98
Oxygen	4.15
Sulphur	1.43
Ash	4.91
Total	100.00
B.t.u.	14,858

It is evident from the above that the Welsh coals are a high-grade fuel, but I do not see any reason to believe they are equal in heating value to the New River product, or superior to the Pocahontas coals.

The New River group lies about 1000 ft. below the Lower Kanawha coals. They take their name from the fact that these beds were mined first along New River in Fayette County, W. Va. They occupy a rock interval of about 325 ft., with the Sewell bed at the top, the Beckley seam 225 ft. lower and the Fire Creek coal 100 ft. below the Beckley. These beds are low in ash and sulphur and have the typical physical structure of a coking coal; their only weakness for this latter purpose lies in their unusual purity, the low-ash content preventing their having a good burden-bearing capacity for furnace use.

MacAlpin Coal Co., MacAlpin, W. Va. Drift Mine with Steel Tipple

The New River Coals

The New River seams are without doubt the best steam coals in the world. The only other fuel product ever compared to them is the Welsh coal. This latter is bituminous in Monmouthshire, but becomes less so toward the southwest, until in Mid Glamorgan, the coal is an excellent smokeless steam product used by the British navy. Toward the west (Pembrokeshire and Caermarthenshire) the seams pass into anthracite. An average analysis of the semibitumi-

In the future, it is probable that these New River coals will be largely used in coke manufacture by mixing them with other coals higher in volatile matter and ash. This practice is already being followed by the United States Steel Corporation at its plants in Illinois.

For steam purposes, and especially for use in naval vessels, where a high heat value and a low rate of depreciation in storage are essential, these coals are un-

equaled. Their low sulphur content makes them comparatively free from spontaneous combustion. Their composition is shown below.

ANALYSIS OF NEW RIVER COAL
(Average of the Three Seams)

Moisture	1.16
Volatile matter	18.22
Fixed carbon	76.94
Ash	3.68
Total	100.00
Sulphur	0.78
Phosphorus	0.010
B.t.u.	15,094

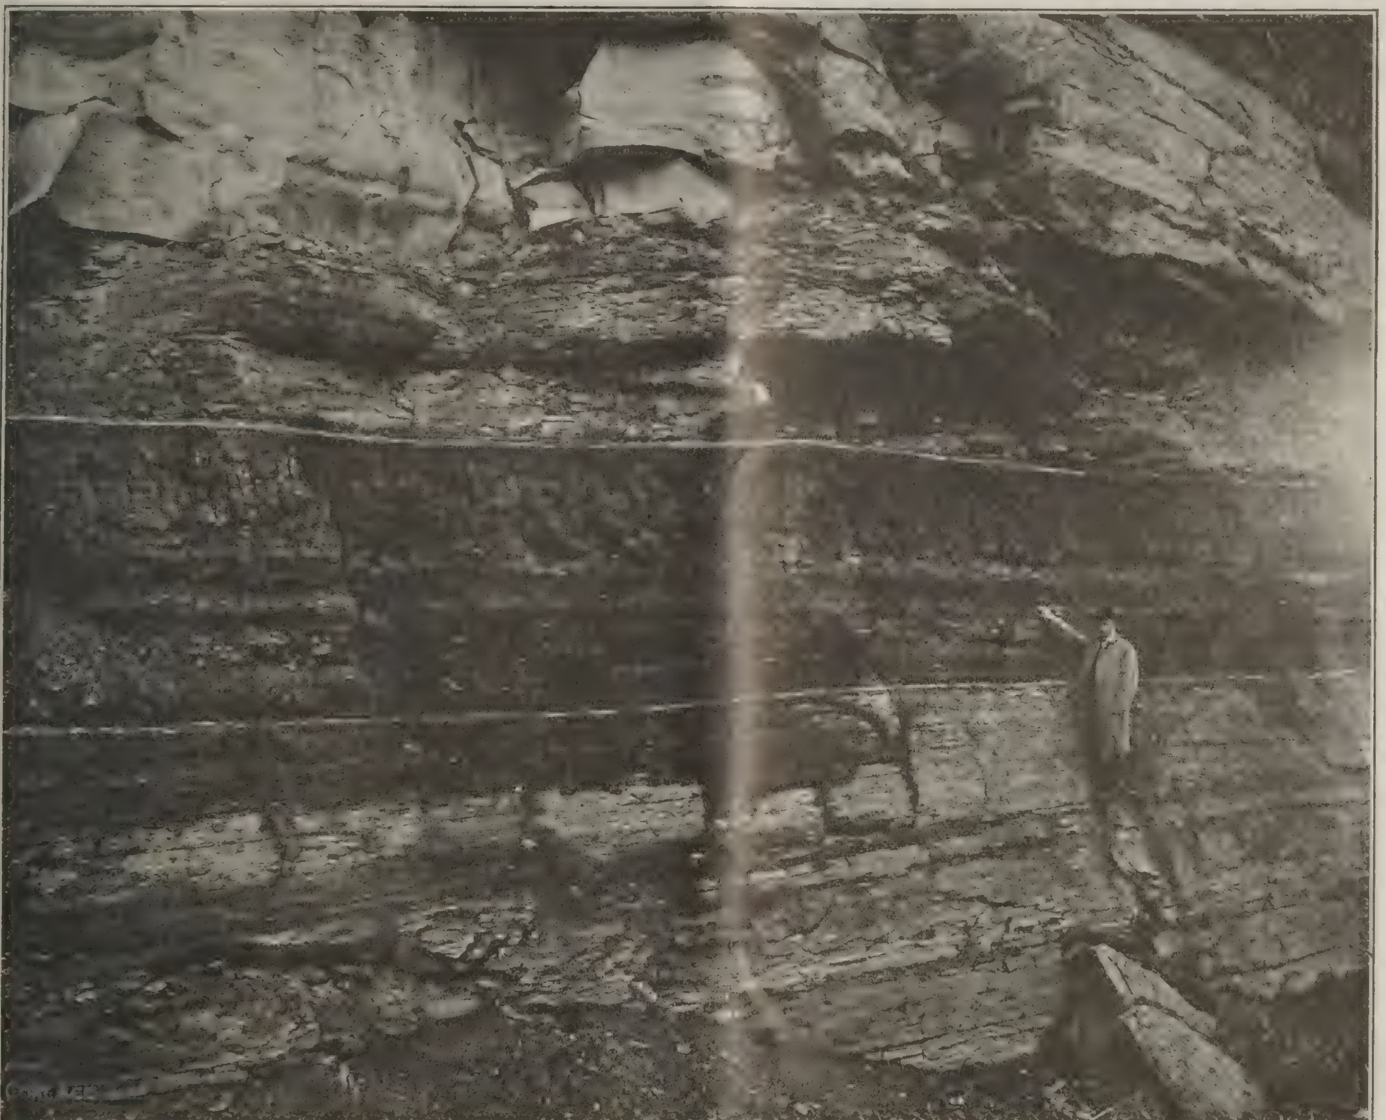
ANALYSIS OF POCAHONTAS COAL

Moisture	1.92
Volatile matter	16.60
Fixed carbon	76.63
Ash	4.85
Total	100.00
Sulphur	0.640
Phosphorus	0.008
B.t.u.	14,947

Estimated Tonnage Available

Carefully prepared reports by Dr. I. C. White, state geologist of W. Va., and the greatest living authority on the Appalachian coals, indicate that within the region tributary to the Virginian Ry. and its branches, there are available approximately 750,000,000 tons of the No. 5 Block coal; more than 7,000,000,000 tons of the Upper Kanawha coals; 8,250,000,000 tons of the Lower Kanawha coals, and 4,000,000,000 of the New River and Pocahontas. This estimate shows a total of approximately 20,000,000,000 tons of coal in the territory traversed by the Virginian Ry. These measures lie adjacent to the road for a distance of 85 miles, as we travel east from the western terminal at Deepwater.

The future of this southern West Virginia field is well assured, (1) because the coal is equal to any fuel anywhere in the world; (2) it is the nearest high-grade fuel to tidewater and will forever monopolize the seaboard trade at Hampton Roads, since no coal further west equals it in quality, and it is, therefore, impossible for any other fuel to cross this field and participate in tidewater shipments; (3) large cities, great industrial corporations and government bureaus are purchasing practically all their fuel supply according to specifications, which are based on the heat units contained in the coal, and as before indicated, the New River product averages higher in British thermal units than any other fuel; (4) the seams are thick, clean, and as a general rule, have good top and bottom, with few faults and squeezes, and as a result, mining costs are as low as can be attained in any other field; (5) labor is unorganized.



An 8-ft. Seam of Clean Coal Exposed by Railroad Cut on Winding Gulf Branch of the Virginian R.R.

Pocahontas Coals

The Pocahontas group lies about 350 ft. below the New River beds, and consists of the Pocahontas Nos. 6, 4 and 3. These coals have a similar physical appearance and chemical composition to those of the New River group, except that the former are slightly lower in volatile matter and have a little higher ash content. This greater percentage of ash makes the Pocahontas coals slightly better for coking purposes.

Markets

New England purchases approximately \$110,000,000 worth of coal every year. Of this annual expenditure, about \$30,000,000 goes to the mine operator, while \$80,000,000 goes to transportation companies and coal dealers. Most recent statistics indicate that of 28,000,000 tons of coal consumed in New England in one year, nearly 20,000,000 tons entered at New England ports, the remainder coming in by rail. If transportation and handling charges, therefore, amount to more than 70 per cent. of the total expenditure for coal, it is evident that the consumer must interest himself in the amount of incombustible matter that the coal contains. For each per cent. of impurities (ash and moisture) a ton of coal contains, 20 lb. of worthless weight must be transported and handled. Furthermore, after the coal has been burned, the consumer himself is obliged to dispose of the greater part of this weight in the form of ashes.

The largest proportion of the New England coal trade should go to operators in southern West Virginia, not only because of the quality of their product, but for the reason that the greater part of the haul is by water, and ocean freight on a bulky commodity like coal is not a large item. For the same reason, the Mediterranean trade eventually will be secured by the operators in this country. We hear much about not being able to secure bottoms, and about the difficulty of engaging a return cargo. Government action favorable to shipping is certain to come, and thereafter we will have ships aplenty. The argument that we cannot contract for sufficient return freight is absurd, and is refuted by all import statistics.

E. E. White Coal Co., Glen White, W. Va.

The South American Trade

The recent English strike permitted some of our operators to get a foothold in the coal markets of eastern South America. Indications already point to our not only being able to hold what business we have taken, but give us reason to know that American coal will surely supplant the European product within a short period of time.

We all realize the importance to the coal industry of the completion of the Panama Canal. There is no plausible excuse for our not commanding the entire trade of western South America. The greater part of this immense new coal business that is about to open to American mine owners should go to operators who ship coal from Hampton Roads. No other product that can be loaded for long-

Gulf Smokeless Coal Company, Toms, W. Va., on Winding Gulf Branch

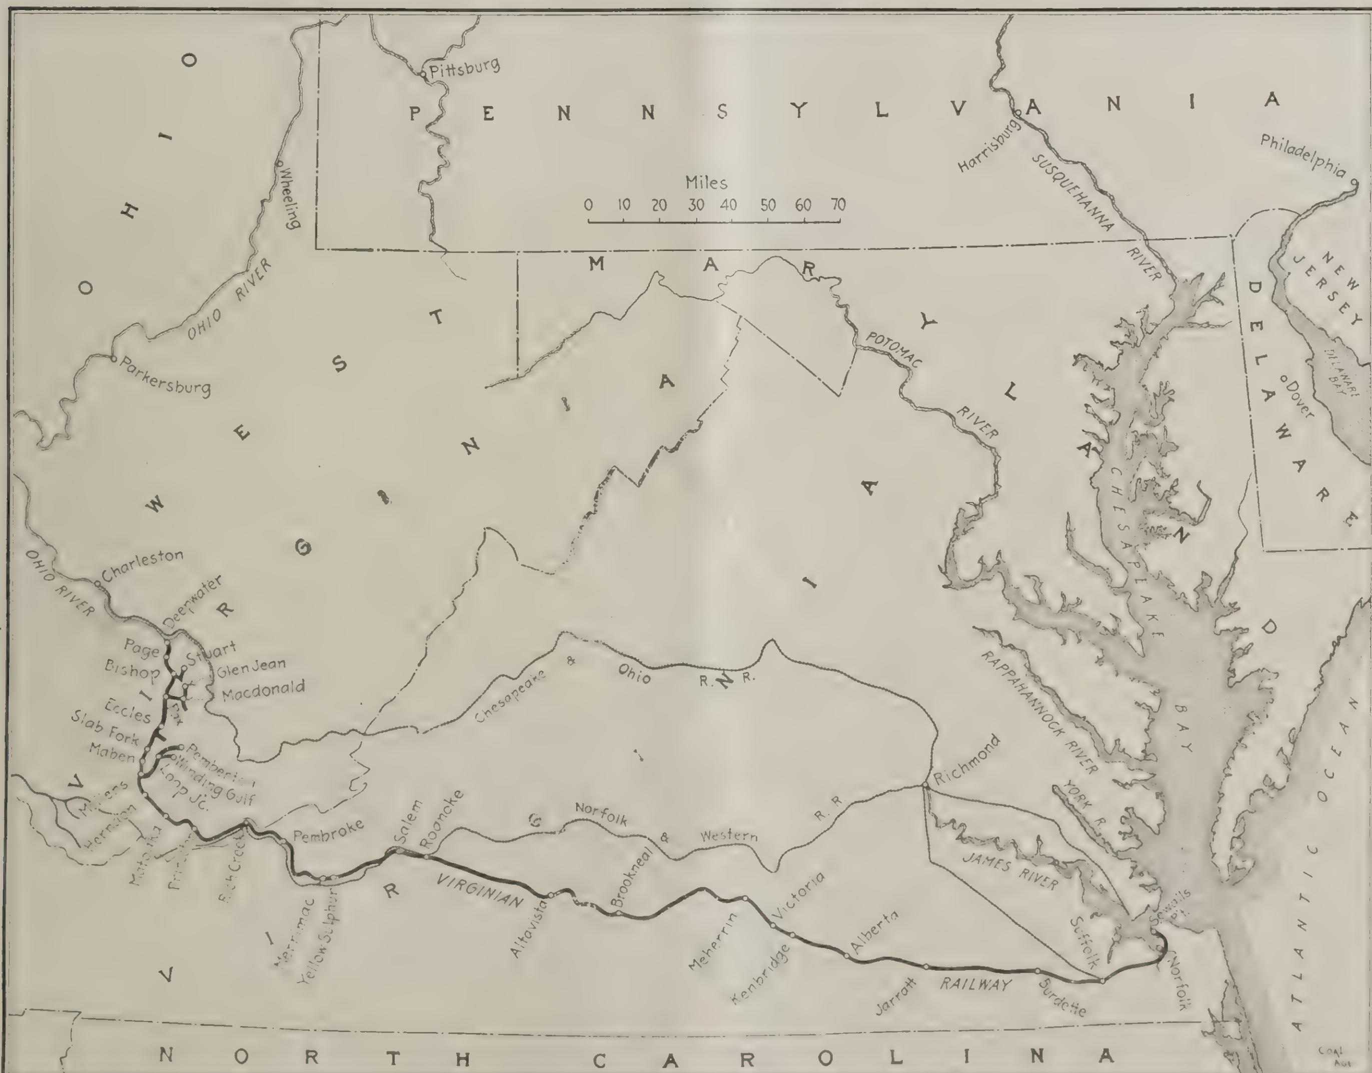
Mine No. 1, Slab Fork Coal Co., Slab Fork, W. Va.

distance shipment will stand transportation any better, or because of low sulphur content, will be more unlikely to spontaneous combustion.

The hope of the coal industry in southern West Virginia lies in the elimination of a shameless, inexcusable and merciless competition that has existed for many years. Recently there has been some improvement in selling conditions, but there are still in the neighborhood of thirteen selling agencies, which is about a dozen more than is necessary. The new business that lies open to West Virginia coal may be secured with present arrangements still in force, but it will be gained quicker and with greater certainty should a couple of powerful "business-getters" go after the markets in an aggressive and determined way.

In conclusion, although I know but little about railroading, I appreciate the great task Henry H. Rogers undertook when he started the construction of the Virginian Ry., and his death, May 19, 1909, 1½ months before the road went on an operating basis, was one of those unfortunate occurrences that seem dictated by the very irony of fate. I believe in southern West Virginia, its product and its men, and in spending practically his entire fortune—$50,000,000—in opening a new empire, Mr. Rogers performed a service to his country and to the people of the Virginias that will benefit posterity, and at the same time, will uphold his sagacity as a far-sighted business man.

[*The next issue of* Coal Age *will contain a short description and views of the coal unloading terminal of the Virginian Railroad at Sewells Point.*]



The Coal Field Tributary to the Virginian R.R., Extends from Deepwater to a Point Just North of Princeton

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Men and "Melons"

The Plymouth Coal Co., through John C. Haddock, its president, makes the following remarks on the anthracite coal situation in extension of his observations quoted in our issue of May 11:

In our first paper, with its citations from the opinion and decision of the Interstate Commerce Commission, in the Meeker-Lehigh Valley R.R. case, we believe that we proved conclusively that if there was a fair and equitable division of the excessive and oppressive anthracite transportation charges, there would be little, if any, difficulty in making a substantial concession to the mine workers, and in the granting of corresponding relief to the independent and individual operators.

As indicated in that statement, the Lehigh Valley R.R. Co., at the close of its fiscal year, June 30, 1910, had an unappropriated balance-surplus of $27,219,780. At the close of its fiscal year, June 30, 1911, this surplus was increased to $30,330,647. On Saturday last, the stock of the Lehigh Valley R.R. Co. sold at $168 a share, while on the same day, the stock in the "melon," the Lehigh Valley Coal Sales Co., sold at $260 a share! During the past ten years, since the award of the Anthracite Strike Commission, the admitted net earnings of the Delaware, Lackawanna & Western R.R. Co. have exceeded $60,000,000. At the close of the year, June 30, 1911, the Reading interests made the following "surplus" exhibit: The Reading Company, $32,287,000; Philadelphia & Reading Railway, $9,665,000; Central R.R. of New Jersey, $13,519,000; surplus of Reading companies, $55,471,000.

Of course, a statement of the operations during the past year, with a careful analysis of working assets and liabilities, would simply add to the magnitude of these impressive figures. They should be a convincing evidence that we have not been hasty nor unjust in pointing out the possibility and necessity of making an equitable and speedy adjustment with the mine workers and the independent and individual operators.

In making further comments upon the relation of the anthracite-carrying companies to the mining interests, we are compelled to point to the Lehigh Valley R.R. Company, not because it is the chief offender, but for the reason that in the Meeker-Lehigh Valley case, the able opinion and decision of the Interstate Commerce Commission, revealed conditions and methods, clearly and impressively, that are simply typical of the entire anthracite field.

Of course, in one respect, the "Lehigh Valley" has an exceptional advantage. The presidents of other roads may have claimed divine appointment. That was merely a claim, but it remained for the "Lehigh Valley" to offer a proof of the possession of a divine attribute, in demonstrating beyond the peradventure of a doubt, by incontestable evidence, that it could perform miracles. The loss of three cents a ton in the carriage of anthracite to Perth Amboy, as asserted before the Interstate Commerce Commission, is converted into a profit that is reflected in its Unappropriated Surplus Account, which grew from $1,620,681, at the close of its fiscal year, June 30, 1903, to $27,219,780, at the close of its fiscal year, June 30, 1910. We are aware that there is an old Celtic dictum, that there should be no miracles among gentlemen, but when a miracle *is* discovered in these latter days, and the manifestation of the gift, is explanatory of a balance sheet, then, we submit, that we should and must recognize it.

In the Meeker-Lehigh Valley R.R. case, before the Interstate Commerce Commission, the railroad company, in its defense, asserted, as reported by the Commission, that the rates on anthracite must be sufficient to produce four results, viz.:

(1) An income sufficient to make up for past deficiencies in current return on investment.

(2) A reasonable current annual return upon the investment in the railroad and transportation adjuncts.

(3) An amount sufficient to provide reasonably for keeping the property constantly up to modern standards, for making such improvements as are necessary to provide for public convenience and safety, and to enable the railroad to get business in competition with other roads.

(4) An amount, sufficient to provide for the return of the principal when, and as the principal becomes reduced and extinguished by the exhaustion of the coal freight.

The commission replies: Under the first proposition, the railroad company argued that the present rates should be sufficiently high to enable it now to earn the amount, by which it has fallen short of paying a 6 per cent. annual dividend in the past, or at least as far back as 1894. It shows that a dividend rate of 6 per cent., applied to its common stock of $40,441,100 for the period from Nov. 30, 1894, to June 30, 1908, would amount to $35,091,276; that during this period the dividends paid amounted to $7,260,264; and argues that upon a 6-per cent. basis, the common stock shareholders suffered a deficiency in dividends during this 14½-year period of $27,831,112.

Assuming, without conceding, that the present producers and consumers of anthracite coal must bear the burden of the misfortunes or mismanagement of a previous generation, it is worth while to inquire whether this claim does not amount for the most part to a declaration, not that the shareholder is entitled to a fair dividend, but rather to an assertion that he may invest his dividends in improvement of the property and have it in cash also.

The devotion of earnings to permanent improvements and betterments was, no doubt, a wise policy on the part of those in control of the road. But the indications are that the shareholders have already received the benefit of that policy, even though it has not come in the form of cash dividends covering the period in question. From 1894 to 1903, the average market value of Lehigh Valley Railroad stock was in the neighborhood of $75 per share. At this writing (June, 1911), the same stock is quoted at $178. Thus a person, who had invested in Lehigh Valley at par, prior to 1904, has benefited by an appreciation in value of his stock to the amount of 5 per cent. per annum since 1894 and has received dividends gradually increased from 2 per cent. to 5 per cent. since 1905. The earnings in 1910 were sufficient to pay a dividend of 20.12 per cent., but the company elected to increase its unappropriated surplus from $19,212,252, in 1909, to $27,219,780, in 1910. Moreover, the Lehigh Valley Railroad Co. has been carrying amongst its assets certificates of indebtedness of the Lehigh Valley Coal Co. amounting to $10,537,000, upon which no interest is collected. Interest on this indebtedness would be sufficient to pay a 1 per cent. dividend on the stock.

We should hesitate to assent to the Lehigh Valley R.R. Co.'s proposition that present shippers must bear the burden of earlier misfortunes of the road, but it is unnecessary to decide that point in this case because it has been sufficiently demonstrated that the shareholders have

received a fair return on their investment, taking into consideration the money actually received in dividends, the increased value of their shares, the increased value of the property, and the large unappropriated surplus.

In reviewing the claims of the Lehigh Valley R.R. Co., we may be allowed to express an opinion as to the character of its first contention, viz.: That its charges should be sufficient to make up for past deficiency in current return on investment.

That it has been done, as has been clearly shown by the evidence submitted, simply makes the wrong committed not only apparent but real. Suppose the mine workers had included in their recent demands, a claim for wages extending back for several years, to cover all lost time, had asked pay for the idle days caused by shortage of railroad cars, accidents in the mining, movement, and delivery of coal; idleness that may have been the effects of dissipation, if you will, would such a presentation have been any more absurd than the present claim that rates of transportation on anthracite must be adjusted to care for every expenditure, however improvident or ill advised, and pay a dividend thereon and accumulate a surplus besides. Are stockholders of an anthracite carrying company in a preferred class and are they exempt, ultimately, from any or all of the liability, incident to bad management? It is notorious that for a number of years, the "Valley" was "skinned" for the benefit of stockholders. The money that was paid in dividends, should have been applied to the betterment of the road. Under the efficient administration of the late president, Alfred Walter, that policy was changed, and his successor, as a result of Mr. Walter's masterful ability and experience, succeeded to the management of a property, adequately equipped and perfected, to serve the public and to meet the competition of its rivals. Well might the commission inquire if this claim does not amount for the most part, to a declaration, not that the shareholders are entitled to a fair division, but rather to the assertion that they may invest their dividends in improvement of the property, and have it in cash also!

As to the remaining contentions of the railroad company, the commission says:

"That the rates should be sufficient to guarantee a fair annual return on the investment and to provide reasonably for keeping the property up to improved modern methods, are sound but have little bearing on this case. It will be noted that the Lehigh Valley's corporate income was sufficient to pay a dividend on the capital stock of 16 per cent. in 1905, 17 per cent. in 1906, 20 per cent. in 1907, 18 per cent. in 1908, 14 per cent. in 1909, and 20 per cent. in 1910. Instead of paying such dividends, it has paid 5 per cent. on its capital stock, appropriated to additions, betterments, and improvements sums ranging from $580,206 to $2,068,590 per annum and has increased its unappropriated surplus from nothing in 1902 to $27,219,780 in 1910. Certainly, it must be conceded that the present rates provide liberally for a fair annual return on the investment and the proper maintenance of the property.

"As noted, the Lehigh Valley R.R. Co. carries amongst its assets $10,537,000 noninterest-bearing certificates of indebtedness of the Lehigh Valley Coal Co. At 5 per cent. per annum, the interest on these certificates would be $526,850. The latter sum is, in all substantial respects, a rebate to the Lehigh Valley Coal Co. The proportion of the total tonnage from the anthracite field shipped by the Lehigh Valley Coal Co. does not appear, but it is of record that it ships about 95 per cent. of the coal to tidewater. If its proportion of the total traffic is the same as that to tidewater, its tonnage for 1910 was in the neighborhood of 10,500,000 tons; and the net result of the transportation as between it and its competitors was the same as if it had had its coal transported for 5 cents per ton less than the independent dealers."

An Outburst of Carbon Dioxide*

A German periodical publishes some information on a sudden liberation of carbon dioxide which occurred in a mine at Altwasser:

As the workings were subject to outbursts of this gas, the mine management always provided an ample ventilating current to dilute that impurity. To reduce the dangers resulting from a sudden liberation of the gas, a series of precautionary measures were prescribed to be observed in the development work. On Dec. 7, 1910, an outburst of carbon dioxide was caused by the firing of a shot. Of the six workmen laboring near the face, four fell in the vicinity of the gallery.

Rescuers Summoned by Mine Telephones

Two of them succeeded in saving themselves and were able to give warning to the men outside by telephone. They then walked to the station where electric lamps and oxygen tanks are kept. The running of the fan outside was at the same time increased as much as possible. Forty minutes after the outburst, the first of the four fallen workmen was discovered. He was carried to the intake airway and was revived by oxygen apparatus. Artificial respiration was applied to the second man, oxygen being also employed. Dr. Brat's apparatus was used on the other two also, but without effect. The corps of rescue men from the "Central Station of Succor" did not arrive upon the spot until the time the fourth victim was discovered.

*Translated by E. P. Buffet for Coal Age, from L'Echo des Mines et de Métallurgie, Paris, France.

One hundred and fifty cars of coal and rock had been cast out by the outburst. The analysis of the air in the gallery gave 7.82 per cent. of carbon dioxide and 14.43 per cent. of oxygen. Breathing in it was very difficult but the air would maintain life.

According to this account of the accident, it appears that the methods of rescue which were available in the mine (the telephone, electric lamps and oxygen) rendered great service and that men from the Central Station arrived too late to do any effectual work. It would be desirable to introduce electric lighting into such galleries, to employ electric shotfiring from a distance and, by the establishment of safety double doors, to prevent the pressure from the disengaged gas from befouling the air of the entire mine.

Mine Inspectors' Institute

The fourth annual meeting of the Mine Inspectors' Institute of U. S. will convene at Columbus, Ohio, June 18, and conclude June 21, 1912. The executive committee will hold a business meeting on June 17. All members of the Institute as well as all state, territorial or provincial mine inspectors in North America are invited to attend the meeting and those not now members are desired to present their applications for membership.

The Ohio inspectors have made extensive provision for the entertainment of those who may attend, and the meeting has promise of being the most successful of any yet held.

Under the provisions of the constitution of this Institute, each state prior to the annual meeting of the Institute has the privilege of placing in nomination the names of the candidates for the several offices to be filled. The president, first vice-president and treasurer cannot succeed themselves in their respective offices.

The offices to be filled, together with the names of the present officials are as follows: President, John Laing; first vice-president, James Taylor; second vice-president, J. B. McDermott; third vice-president, D. C. Botting; treasurer, Thos. Morrison; secretary, J. W. Paul; asst. secretary, F. W. Cunningham.

A tentative program has been arranged which includes a number of interesting addresses and the presentation of papers on many pertinent subjects. The works of the Jeffrey Manufacturing Co. will be visited and a banquet held at the Great Southern Hotel, in the evening of June 30.

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

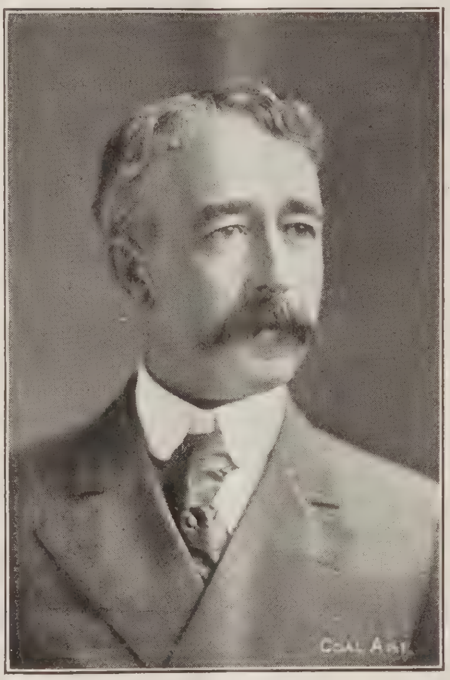
Coal mining is one class of work a man has to be born to, and if a fellow doesn't relish the smell of the air in the upcast shaft, he had better throw up his job and get a new position as clerk in the perfumery department of a big department store. Ability to stand hard knocks, grit to stay to the finish and a nature that fears neither man nor devil, are requisites to success. The fellow who lacks fear through ignorance is a menace; the man worth while is the one who can perform his work day after day, conscious every minute of the dangers that surround him.

Of course, the time does come to each diligent coal-mining man when his trips to the face grow less frequent; more time is spent in God's sunshine, and the younger element must bear the burden of the underground work. To be a real success, however, it's necessary to have gone through the mill, and many a manager today would be better for having lived longer at the face, and experienced some of the trials and tribulations of the men who labor beneath the ground.

Eli Conner always struck me as typical of what a coal man should be. The marks acquired by a regular in the army or a sailor at sea stick through life even when the individual turns to civilian pursuits. It is just so with Mr. Conner; there's something about him that reminds you that he has plugged up and down many an entry, head bent, dodging low places and projecting timbers, and, believe me, Eli has to do some bending in low places for a six-foot rule will hardly reach from the ground to the place where he parts his hair.

In Mr. Conner's particular case there has been no retirement, even temporarily, from the mines. Since way back in 1864, when he first saw daylight at Mauch Chunk, Penn., there has been but little time when the call of the mines hasn't been ringing in his ears, so getting out of practice has been an utter impossibility. Educated in the public schools of his native town, he continued his studies privately under the eyes of certain mining engineers whose names are history in the industry.

In 1882, Mr. Conner was employed by M. S. Kemmerer & Co., at Sandy Run, Penn., in the Lehigh region of the anthracite coal field. He served in various subordinate capacities under the superintendent, Walter Leisenring, and later became the engineer of the Sandy Run & Pond Creek collieries, which



Eli T. Conner

mines were operated by the Kemmerer people.

In the fall of 1883, he was sent to Harleigh, Penn., where another mine of the same company was located, and while there served first as shipper and engineer, later (1885) being made superintendent of the mine. In December, 1885, the Harleigh colliery, as well as the adjoining one, known as Eberdale, were filled with water, due to the disastrous floods of that year. After this occurrence, Eli returned to Sandy Run as engineer and assistant superintendent.

In the fall of 1887 and the spring of 1888, Mr. Conner had charge of the construction of the Moosic Mountain & Carbondale R.R., extending from Peckville to the Moosic Mountain colliery. In September, 1888, he became superintendent of the Mount Jessup Coal Co., which was controlled by the Kemmerer and Leisenring interests. In 1894, upon the death of the late Austin Moore, he was appointed superintendent of the Florence Coal Co., and of the Spring Brook Coal Co.; all this in addition to his duties as superintendent of the Mount Jessup mines. While in charge of the Spring Brook colliery, Mr. Conner designed and erected a complete new plant on the property, located near Moosic, Penn.

In the spring of 1896, the Lehigh Valley Coal Co. purchased the operations of L. A. Riley & Co., at Centralia, Penn., in the Shamokin district. The late W. A. Lathrop, who was then general superintendent of the Lehigh Valley Coal Co., selected Mr. Conner as superintendent of the new Shamokin division, which included the Riley operations and all other properties of the Lehigh Valley Co. in that region.

In December, 1896, I. R. Moister, superintendent of the Wyoming division of the Lehigh Valley Coal Company, died. Mr. Conner was transferred from Centralia to Wilkes-Barre as his successor. The Wyoming division is the most important part of the company's interests, and includes the properties of the Connell Company and the Seneca Company, which properties were purchased by the Lehigh Valley people during the time that "Eli T." was superintendent of that division. While in charge of the "Valley" mines around Wilkes-Barre, Mr. Conner designed and erected a new plant at Prospect colliery, which mine now holds the record as being the largest single producer in the anthracite region. The output through this breaker last year was in the neighborhood of 1,200,000 tons of marketable product.

In the spring of 1902, Eli Conner was selected by W. A. Lathrop, then president of the Webster Coal & Coke Company, to fill the position of general superintendent of that company, with headquarters at Cresson, Penn. During this time the Webster Company was merged with the Pennsylvania Coal & Coke Co.

In 1907 "Eli T." accepted a position as general manager of the New River Collieries Company, a consolidation of mines bought up by the Guggenheims, and located in the celebrated New River field of West Virginia.

In the spring of 1909, Mr. Conner gave up his work in West Virginia and opened an office as consulting mining engineer in Philadelphia. A year ago he was retained to make an exhaustive investigation of all the properties of the Delaware & Hudson Co. in the northern anthracite field.

Eli Conner was also retained, together with another engineer, Wm. Griffith, by the city of Scranton to investigate mining conditions under that city with relation to mine caves. The advisory board, under whom this work was done, consisted of John Hays Hammond, W. A. Lathrop, D. W. Brunton, R. A. F. Penrose and L. B. Stilwell.

CIRCULATION STATEMENT

Of this issue of Coal Age, we will print 7500 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.

This journal has a direct aim—a single purpose—which is to help advance the coal-mining industry. Its creed embodies the dissemination of knowledge and the free interchange of ideas among its readers, all of whom are invited to become regular contributors.

Contents

COAL AGE

The Cost of a Strike

A review of the effects of the British coal strike, on industrial conditions in general, presents an interesting example of the importance of coal in the business world. No previous coal controversy was ever conceived along such broad comprehensive lines, or so disastrously effective in its consummation.

One of England's eminent economists estimated the loss to Great Britain as not less than 50 million dollars per week, and suggested that since the aggregate demands of the miners totaled only a quarter of a million annually, these demands should be acceded to. This appears a very simple and reasonable solution of the problem, but he unfortunately neglected to provide a means for securing the necessary quarter of a million.

One of the most noticeable features of the British strike was the almost immediate curtailment in the associated industries. Four days previous to the suspension there were 284 pig-iron furnaces in blast, and nine days after, two-thirds of these were idle, while at the end of 30 days only about one-seventh remained in operation. In the tin-plate industry there were 489 mills in operation at the beginning of the strike, and one month later 413 of these were shut down. Of the half million men employed in the manufacture of iron and steel, less than 190 thousand remained at work at the end of 30 days.

Nor were these suspensions confined to the iron and steel industries. Twenty-three days after the strike was called, over three-fourths of the pottery workers and one-fourth of the brick workers had been laid off entirely, while many of the latter were working only part time. Engineering projects in general were seriously interfered with and there was much unemployment among seamen, coal trimmers and dock laborers.

In thirteen representative industries, employing 330,000 men, 7 per cent. were thrown out of employment at the end of 23 days, and there was a shrinkage of 12 per cent. in wages. The average percentage of unemployed, 30 days after the strike went in effect was 11.3, as compared with 2.8 at the beginning, and 3.0 for the corresponding day the year previous. These figures do not include the mine workers themselves, practically all of whom were out during these periods.

Leveling Down

The hope of the workman who strives for a minimum wage per day is, that by so doing there will be a leveling up, but unfortunately this is too often unrealized. It appears that the minimum wage in Great Britain is going to follow the general rule, and a dead and low wage level will result which will be disadvantageous to the workingman.

Everyone has expected that the cost of producing coal would be increased by the new provision, but recent developments tend to show that the opposite action will result. The expectant miners congratulate themselves that they emerge from the conflict in triumphant possession of the existing piecework system, whereby they earn high wages when working in good places and to the best of their abilities. They expect that in addition to these advantages, they will also enjoy the benefit of a time wage—a guaranteed daily wage when working in bad places or when failing to put forth their best efforts. The miners expect the combined advantages of piece work and time work, but none of the disadvantages of either system. If that iridescent hope were realized, then, of course, the cost of coal would be unreasonably enhanced.

It must be observed, however, that human nature being what it is and the conditions of coal mining being what they are, a guaranteed time wage must carry with it constant supervision in order to check malingering. Under the piecework system, supervision is hardly required, but time work or day wages must be accompanied by much supervision.

The longwall system in use in England makes close superintendence more possible than in the United States, but at

the same time, while one foreman may boss a hundred men in a work shop, in the workings of a coal mine it would take him all his time to supervise a small percentage of that number of men. A mine employing a thousand miners would need possibly almost one hundred foremen. Obviously the industry would endeavor to evade such a burden as this. The problem of supervision would have to be faced and solved whether the miners liked the solution or not. If they enforce the minimum wage they will take the consequences which naturally arise from such a system.

Under the new law, elderly, delicate, slow and inefficient men will be weeded out. Only the efficient will be employed, and they will have to exercise their efficiency. What is called the "Butty" system, already in existence at a few mines and strongly resented by the best of the men, will be made universal. The "Butty" is a kind of contractor and he will be given charge of a stall or room, a longwall or a number of working faces. He will contract to get the coal at the existing price, employing the necessary miners, timberers and car-pushers. The men will be under the strict supervision of the "Butty"; they will get the minimum wage and no more, but for that low wage they will have to do the maximum amount of work. Thus they will work at a piecework pressure for a time wage, and the "Butty" will pocket the surplus money.

One good feature of the change will be that there will be a large increase in the use of mechanical coal cutters in some of the seams. Possibly a few of the poorer and meaner beds will be abandoned. Nothing is more patent than the fact that before long the miners will be completely disillusioned in the outcome of their agitation, and it is probable that other strikes will result, in order to produce the desired corrections along other lines. The "Butty" system is especially to be deplored as it amounts in a degree to an exploiting of the work of less skilled laborers by their more fortunate coworkers. An analogy on a small scale has been observed for many years in the anthracite region of this country in the relation borne by the miner to his laborers.

Perhaps the strike may do a great deal of good in exhibiting to a numerous body of British workmen, the inexorable character of the national economy. Time and again there has been a disposition to divorce payment from efficiency, and wherever that is done the inevitable result is to reduce the payment for labor performed. It is getting harder and harder to understand year by year that wages are not an artificial institution of modern society. They are rather a gift of nature in return for work duly performed, and cannot be regulated as a whole by any whim of the governing body. A resolution on the part of all mankind to live more comfortably must always be accompanied by a resolution to increase productivity. We can meddle with the distribution of wealth, but its total quantity is the outcome of the efforts of present and past economies.

Carbon Monoxide

A certain percentage of carbon monoxide can probably be inhaled without injury to the human organism. In fact, it has been found that it is generated in at least one mine in Germany, and in such mines the coal workers must normally breathe small quantities of the gas. The report of the Prussian Firedamp Commission shows that at the Glückhilf colliery, Waldenburg, Lower Silesia, carbon monoxide was found in large percentage. A drift running to the dip was found to contain 1.87 per cent. of this gas as a constituent of its atmosphere.

In a communication of M. Mahler to the Academie des Sciences, he details tests of gases from coal dug in mines located at Decazeville, Azincourt, Courrières and Anzin. When this coal had been powdered and exposed to the air, carbon monoxide among other gases was given off.

When exposed to a current of air for 30 hours, at a temperature of from 77 to 86 deg. F., the coal previously freed from hygroscopic moisture and occluded gases, emitted 2.4 per cent. of its volume of this gas. When using coal containing the ordinary mine moisture, the generation of carbon monoxide was reduced to 0.94 per cent., even though the temperature was raised to 95 deg. Fahrenheit.

This suggests much activity in the production of the gas, the dry coal appearing at low temperatures to produce nearly three times as much monoxide as dioxide. Bovey Heathfield lignite gives off gas containing 1.20 per cent. of carbon monoxide at 122 deg. Fahrenheit.

It has long been debated whether the human blood contains carbon monoxide under normal conditions. It was stated by G. A. Buckmaster and J. A. Gardner in 1909 that three dogs showed a volumetric percentage of carbon monoxide in their blood of from 0.144 to 0.16 per cent. It is interesting to point out in this connection that in air containing 0.2 per cent. of monoxide, a mouse will show decided symptoms of distress in 8 minutes.

We are not obliged, however, to accept the dictum of these physiologists alone. Other experimenters have found such traces of the gas in the blood of invertebrates, but its presence was frequently attributed to the chloroform used in killing the animals. Messrs. Buckmaster and Gardner show that the impregnation of carbon monoxide is not the result of their manner of death, but is a normal constituent of the blood.

Wages and Financial Stringency

One of the effects of increasing wages, which has been more generally overlooked than its importance justifies, is the need of an increasing capital to meet them. If wages double, the capital account must also be doubled or credits must be reduced. Thus an increased stock of money will be needed in order that a continuous volume of business may be conducted.

Increasing wages reduce the effectiveness of the monetary tokens. If it takes a half more capital to engage in business, then only two-thirds of the business will be done. Short time for many of the workers, and lack of employment for the rest, results. This may be circumvented by creating paper substitutes, with resultant reductions in the value of the medium of exchange. Thus a meretricious wage will be paid with a meretricious currency, and if the silver or paper is accepted as sound and desirable, we shall have phantom chasing phantom till the people learn that shadows are shadows, and that bread and comforts are the only realities, acknowledging that money is only a medium of exchange and wages are only a fluctuating equivalent for victuals and raiment.

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

A Comment on the Jed Explosion

The time has arrived when, in the interest of humanity, every mining man should take a part in a propaganda devoted to the dissemination of knowledge for the purpose of warding off these ever recurring explosions in the future; and I know of no more effective method of accomplishing this end than to analyze the facts surrounding those that have occurred, and especially the last, that of the Jed mine disaster.

Justification of the State Mine Inspectors

Was this disaster unavoidable? Were not the officials forewarned of the lurking danger? Did not the state mine inspectors fulfill their duties when, shortly previous to the accident, they caused operations to be suspended? The permission granted by the court to reopen the mine, ignoring the order of the mine inspectors which commanded the use of locked safety lamps, was a sad instance of the miscarriage of justice. Such restraints handicap the mine inspectors in the discharge of their duties, and this interference with their prerogative lifted the responsibility from their shoulders and placed it upon the court and the officials of the mine.

Was the Jed mine as uptodate as claimed by the correspondent, in Coal Age of Apr. 6? In that article it was stated: "The work of the rescuing party was balked by falls of slate and many of the bodies were found covered by falls," and again, "The draw slate which is 12 to 18 in. thick is taken down in the main entrances but held up in the rooms and airways by timbering." Is this a good system of mining? Would it not be safer and cheaper to take down this 12 to 18 in. of draw slate, say 12 ft. wide in the rooms and airways, as well as in the main entries? Eventually this draw slate will fall before the time of drawing pillars; consequently it will have to be removed; why not do it in the first place, and save the cost of timber, and timbering, and possibly a life? Is it not possible that some of the victims whose bodies were covered by falls may have escaped the force of the explosion?

The correspondent says further:

"The fan was crippled, it is true, but nevertheless it was kept running." My theory of an uptodate mine generating gas and coal dust in dangerous quantities would call for an emergency fan available for immediate use in case of damage by an explosion or accident from any other cause that might put the fan out of commission.

Some Pertinent Theories

Note again: "Day shift starts at 7 a.m. Explosion occurred at 8:10 a.m.," and there is great significance in this fact. As is well known, it is a custom with miners to gather in small groups the first thing in the morning for conversation before beginning work. The explosion evidently occurred about the time they got into their places and finished drilling holes for the "breaking down shots . . . which are fired at the same time throughout the mine," for it seems that such was the custom, as well as to have the undercutting done during the night, the night shift quitting at 4 in the morning.

It is a question whether or not the dust from the undercutting would be thoroughly settled, before being set in vibration again by this artillery of breaking shots that went off in rapid succession at about 8:10 on this fateful morning. Again: "The fireboss had charge of the night shift." Did he examine the mine between 4 and 7, or did he quit at 4 with his men? The latter being the case, what changes might not have occurred between the hours of 4 and 7?

The statement that the mine foreman and three others were lowered into the mine immediately following the hoisting of the 12 men who escaped, justifies the conclusion that the mine foreman was not on duty early in the morning. Knowing that it was after pay day it was his duty to be at the mine early to see that no man be allowed to enter the mine in an intoxicated condition, or in that nervous state characteristic of a man recovering from the effects of over-indulgence in intoxicants. Permit me to call attention to the fact that the explosion at Harwick in the Pittsburg, Penn., district occurred on Monday, directly after pay day, and I think that laxity on the part of foremen in allowing men to enter the mines before they have recovered from the effect of their pay-day celebrations, has been a potent factor in the various disasters that have occurred in gaseous mines.

Mine Supt., Murray, Penn.

Effect of Uncontrolled Competition and Need of Price Associations

In view of the growing sentiment among coal operators in the United States to the effect that selling syndicates or equivalent associations are becoming an economic necessity in this country, the following letter from a British correspondent will doubtless interest a number of Coal Age readers.

Opinion is strengthening in the British coal fields that with diminished competition there would be less waste of coal resources; incidentally it is being shown, to some extent at least, how the high coal exports of the country are being maintained. These exports are increasing by leaps and bounds, and D. A. Thomas, the South Wales authority who is closely associated with the Cambrian combine, is quoted to show that the national aspect of the question is of vital importance.

The following quotation is extracted: "We are exporting large quantities of coal at less than cost price; we are, in fact, giving away to the foreigner with insane prodigality our mineral wealth—wealth that is by no means inexhaustible and cannot be replaced."

If Mr. Thomas is right, it is easy to understand how a huge foreign trade may be built up; that is, if giving away can be said to have any relation to trading. The critical state of the situation is further emphasized by Sir William Ramsay's note of alarm before the British association, regarding the possible exhaustion of the coal supply.

G. R. Carter, M. A., of the Department of Economics, University College of Wales, referring to the same condition, says the reckless competition of coal owners, middlemen, etc., in the sale and distribution of coal, especially that intended for export, produces consequences upon the coal industry quite as real and disastrous as those occasioned by wasteful methods of mining or of coal consumption.

To check this loss and waste he favors the formation of price associations between the various coal owners, which might neutralize the increasing tendency of competition to reduce prices to a minimum. In Germany, Austria, Belgium and the United States of America, Mr. Carter says, these combinations for the maintenance of prices have come to be considered well nigh indispensable to the

welfare of the coal trade. The Chenish-Westphalian coal syndicate, probably the best organized and most effective combination in the world, enjoys the fullest favors of the German government. In fact, the State itself is a member of the price associations, owing to the existence of state-owned coal mines. These associations have been found valuable, Mr. Carter adds, as a means of steadying the coal trade, fostering the exports, checking the development of doubtful mining projects, etc.

In the foregoing remarks it is clear Mr. Carter concentrates on the South Wales coal field, because he believes that a scheme for the maintenance of prices is a necessity there owing to the utter dependence of the community in South Wales upon the welfare of the coal industry. The leading points in his argument are:

1. "The unrivaled quality of the coal extracted in South Wales makes it an article of prime necessity under modern conditions; it is indispensable in the world's markets. Both Welsh steam coal and the anthracite of West Wales possess many elements of monopoly value, which give South Wales coal owners enormous advantage over other competitors at home and abroad. It might be asserted that their coal must be obtained at any cost.

2. "Again, the natural location of the coal measures is favorable. The coal field is concentrated in area, the seams are easily accessible, transportation facilities are abundant. The production of a large proportion of the steam coal is in the hands of a comparatively small number of companies whose interests are well ramified."

It is said, however, that the competition of rival producers within this favored area is more serious than that of competitors outside this field, and Mr. Carter assumes it would be more profitable that they should unite their energies in order to obtain the fullest value for their products rather than weaken one another by ruthless undercutting, "all for the advantage of foreign purchasers in most cases."

A pregnant paragraph reads:

"Prices, profits and wages are inseparably and intimately bound up with one another. They all suffer from the effects of unchecked competition. Employers seek to recoup themselves for low prices by shifting the burden of loss onto the miners through a reduction in wages. Any downward tendency—and this is the inevitable tendency of competition—furnishes immediately a source of trouble and conflict in the coal field. When prices are tending downward of themselves the keen competition of sellers only hastens and aggravates their fall. Similarly, the lack of concerted action seriously delays any tendency making for a rise in prices."

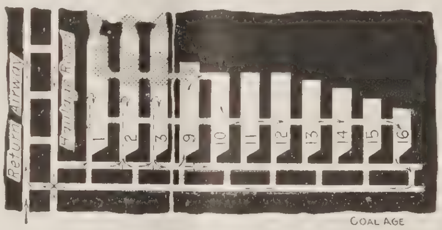
The above discussion is suggestive and may teach some important lessons.

BENJAMIN ADDICKS.

Wigan, England.

A Cave-In Proposition

My attention was called a short time since to a serious proposition in the way of a cave-in at the face of nine rooms driven off from an entry. The cave closed the inside breakthroughs between these rooms and shut off all of the ventilation from the rooms. The roof fell to a great height above the coal so that, in places, there were cavities of several hundred cubic feet in the roof. There were sixteen rooms turned off this entry, the first nine of these being closed, as stated, by the cave at the face. The proposition presented was to properly ventilate these fallen rooms so as to prevent the accumulation of dangerous quantities of gas in them.



SHOWING MANNER OF VENTILATING ROOMS CAVED AT THE FACE, BY BRATTICES

I suggested the plan shown in the accompanying sketch. This was to place a curtain across the entry at the mouth of each room so as to form a brattice extending into the room and which would deflect the air current toward the face. The plan proved successful and kept the rooms free of any dangerous quantities of gas.

JOHN SUTTON,
Fireboss.

West Terre Haute, Ind.

Expansion Bit for Drilling Coal

I wish to draw the attention of readers of COAL AGE to a new kind of drill having an expansion bit that seems to me would be of great advantage in drilling either anthracite or bituminous coal. I would like to see a good discussion of the use of this bit in drilling coal.

The bit is so arranged that it will expand automatically in the hole and is adjustable. By its use a small hole can be drilled to any desired depth and the bit expanded, at any point, so as to drill the remainder of the hole with a larger diameter. It often happens, in drilling a hole with a common bit, that the diameter of the hole grows smaller toward the bottom; and the charge cannot be pushed safely to the end of the bore. This difficulty would certainly be overcome by using an expansion bit such as I have described.

The question I would like to see discussed is, would not better results be obtained all around, in charging and blasting, when the hole is slightly enlarged at the inner end occupied by the charge. Of course, it would be necessary to properly charge the hole; but the pressure on the tamping would be less, and the danger of the shot blowing out its tamping much reduced. It is possible also that the number of holes required would be reduced.

It is well known that miners in anthracite mines commonly drill a 2½-in. hole to a depth of 5 ft. This means a grinding out of about 5×12 (0.7854×2.5^2) = say 300 cu.in. of coal. Now, if an expansion bit could be used to drill a 1½-in. hole and expand this to, say 3½ in., at the lower end of the bore, the area being doubled, the charge would occupy only one-half the length it filled in the 2½-in. hole. If the charge filled 20 in. in length in the first hole, it would only require 10 in. in length in the expanded portion. This would reduce the cuttings for a 5-ft. hole from 300 cu.in. to 188 cu.in., or about 37 per cent.

If this is practical the saving effected is well worth while. At any rate the scheme is worthy of consideration. The concentration of the charge in the end of the hole would prove a greater advantage in a hard-shooting coal than in a soft, friable coal, or a coal that has a tendency to "seam out." Let us hear from some of our experienced miners. Perhaps some have used or are using this bit and can give us the benefit of their experience.

A MINER.

Wilkes-Barre, Penn.

Timbering a Mine Parting

In reply to Noah Burton, Anglin, Ky., COAL AGE, March 23, p. 786, I would say posts between tracks are dangerous. However, Mr. Burton does not mention the width of track or of cars. I will, however, assume the width of cars to be 4½ ft., and a 4-ft. clearance between cars, and 6-in. clearance between car and rib, on each side. Therefore, $4.5 \times 2 = 9$ ft. for cars on both tracks; plus 4 ft. between cars, plus $2 \times 6 = 12$ in. or 1 ft. for clearance on each side = 14 ft. in all, which is the least possible width. Then, allowing 9 in. for each end of the crossbar in a hitch, will require crossbars 15½ ft. long.

It would be best to use 8- or 10-in. I beams, spaced 4½ ft. centers and lagged with either short pieces of rail or 2 in. plank. Mr. Burton does not state the thickness of the seam. I would suggest making a blind parting, with two or more crosscuts open for mules to pass. It will possibly be necessary to drive an air-course to do this, which will, perhaps, be the cheapest in the end, depending on the life of the parting.

DAVID FULTON.

Marion, Ill.

Inquiries of General Interest

All Questions Must be Accompanied by Name and Address—Not for Publication

Blownout and Windy Shots, Their Cause, and Precautions to Avoid Them

(a) Explain the difference, if any, between a "blownout" and a "windy" shot; are they both equally dangerous? (b) What are the causes of such shots and will a dusty atmosphere or accumulations of fine dust, at the face, when no gas is present, produce the same effect?

La Salle, Ill. MINE EXAMINER.

(a) A blownout shot is a shot that has blown its tamping instead of breaking the coal. A windy shot is one that expends a considerable portion of its energy on the air, causing a heavy concussion of air due to the large and rapid expansion of the gaseous products. Both are dangerous, but the degree of danger will depend on the condition of the immediate workings with respect to gas, dust and ventilation. A blownout shot develops a greater heat energy and is more dangerous, owing to its intensity, than a simple windy shot, which may do no harm in case the workings are free from gas and dust.

(b) The main causes of blownout shots are: Poorly located shot holes, insufficient undercutting, or holes put in beyond the depth of the undercut, shooting from the solid, insufficient or careless tamping, tamping material not being plastic and incombustible, and consequently not airtight, and the use of an excessive amount of explosives. Except in anthracite mining, shooting from the solid is a dangerous practice under the best of conditions, but it is doubly so in chambers located near a return airway containing inflammable gas or in chambers where a blownout shot may discharge into the gob or into a dusty main-haulage road.

A windy shot is often the result of firing a heavy charge in a dusty place; or a place where the ventilation is poor; or firing two or more shots, in quick succession, in a close or confined heading.

The experiments made at the government testing station at Pittsburg, Penn., have shown that coal dust will explode even if free from gas. Explosions of gas are usually more or less local in character, but the explosion of dust, which is present throughout the mine, may traverse rooms and entries, and even wreck buildings at the entrance of the mine.

When about to drive a shot hole, make a careful examination of the place and judge the nature of the material to be blasted and that of the overlying strata. Keep the hole as cylindrical as possible, so that the cartridge may be easily slipped into position. See that the hole is put down on the line of least resistance. Undercutting for firing in coal should be a little deeper than the shot hole, to avoid the danger of a "tight" shot that may blow the tamping.

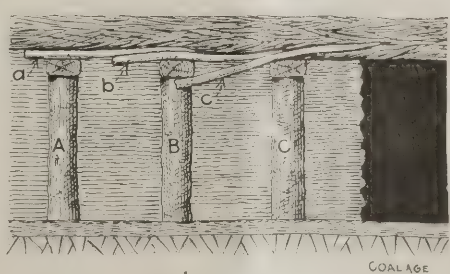
"Forepoling" in Mine Timbering

What is meant by "forepoling" in mine timbering and what is its purpose? Kindly explain the method in detail.

Pocahontas, Va. TIMBERMAN.

The forepoling system of timbering consists in supporting the roof right up to the coal face with provisional wooden or iron bars, driven forward over the collars as the working face advances until there is room for another row of timbers. The available height of the seam is somewhat lowered by this method, and this fact is an important matter in the case of low seams undercut by machine, but with a friable roof this system means additional safety.

The general method of forepoling is shown in the accompanying figure. The spiles or forepoles *a, b* and *c* are driven over the crossbars *ABC*, in their respective turn.



SHOWING METHODS OF FOREPOLING

These spiles are narrow plank, 2x6 in. or 2x8 in., sharpened to a broad, flat edge. Each set of spiles is driven up, at a low angle, over the collar or crossbar of the last set of timbers, close to the face of the heading, and under the next preceding set, as shown at *c*, in the figure. These spiles protect the miner while he is advancing the face far enough to set another timber frame. When this is done, the next set of spiles is driven under the collar of the framing *C* and above that of the new framing just set. When this has been done, the spiles *c* are driven forward to a position corresponding to *a* and *b*.

Advantage in Employment of Shotfirers

What is the advantage of employing shotfirers in coal mining? Is the system in use, anywhere, of firing all the shots in the mines, at once, by means of electricity, from the surface?

Minersville, Penn. MINE FOREMAN.

When shotfirers are employed the shotfiring is all done at night when there are the least number of persons in the mines and the risk which always attends firing can be reduced to a minimum. During the daytime, doors are constantly being opened and closed, all of which affects the ventilation, which in turn affects fires or explosions due to shotfiring. Fresh gas is also being constantly liberated in the daytime, and clouds of dust are continually being raised, all of which increase the dangers of day-shift shotfiring. Night firing, which may be described as an ordinary precaution, eliminates all of these dangers.

In Alabama and Utah, electric firing is done by specially appointed firemen, who enter the mines at night while they are empty, connect up the wires, and then return to the surface, where they make the connection of the circuit, thus insuring blasting in a mine empty of all workmen, so that even if the mine should be badly damaged or even destroyed, no lives can possibly be lost.

Powder in Illinois

How much coal will the average miner produce for every keg of powder used?

Spring Valley, Ill. MINER.

In 1910, the last year for which full statistics are as yet obtainable, the total number of employees at mines was 74,634; the total ouput of the mines was 48,717,853 tons; the number of kegs of powder used for blasting was 1,254,095. In the 11 years since 1899, the output has just about doubled, while the quantity of powder has practically trebled, giving an average production, for this period, of nearly 39 tons of coal per keg of powder used. The production of coal per keg of powder used did fall to 32.28 tons in 1908, which was the lowest point reached. This powder cost the miners at the average rate of $1.75 per keg.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Anthracite Mine Foremen's Examination in Pennsylvania, April, 1912

(Selected Questions)

Precautions in Blasting

Ques.—Having charge of a mine in which locked safety lamps are used, what precautions would you take before firing?

Ans.—Every hole should be inspected before it is charged, to ascertain its depth and direction, the condition of the coal, and to estimate as nearly as possible the weight of charge required for the work. This should be done by a competent miner, whose experience in shooting coal fits him for the work.

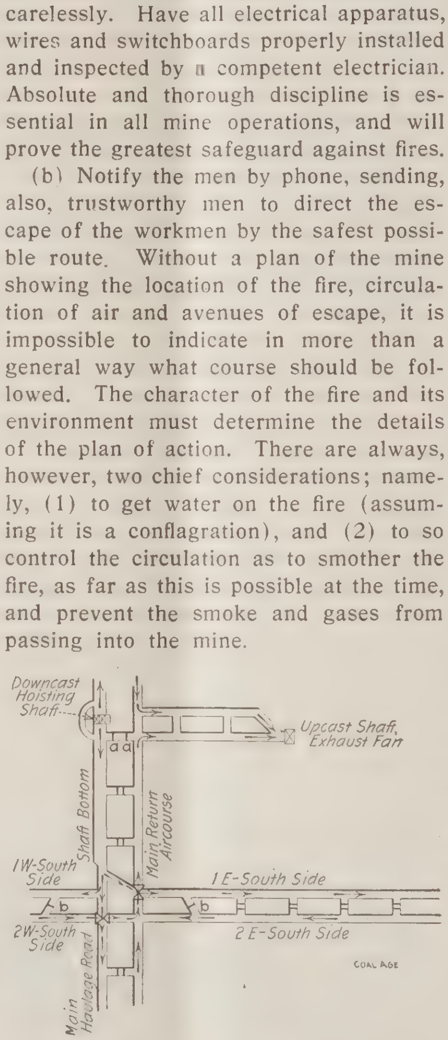
Assuming the hole has been properly inspected, charged and tamped, before it is fired, the place and those adjoining must be carefully examined for gas; care must be taken to see that the usual quantity of air is passing and the place free from undue accumulations of dust. If much dust is present, although anthracite coal, it may be advisable to water the face, roof, floor and sides for a few yards back, to avoid what might prove a windy shot. Fuse should not be used; but all shots should be fired with squibs or by electricity, after giving suitable warning to men working in adjoining places.

Mine Fires, Precautions, Etc.

Ques.—(a) Having been placed in charge of a large mine, what precautions would you take to prevent mine fires? (b) If a fire should occur in the intake of your mine, what would you do?

Ans.—Make and enforce strict regulations in regard to the handling of all combustible material, especially hay, oil and explosives, in and about the mines. Forbid the storage of such materials in or near the shaft, or the carrying of larger quantities into the mine than are required for the day's use. Forbid the use of mixed lights in the mine, and allow no unprotected lamps or torches at the shaft bottom, or in pump rooms, engine rooms or stables. Adopt a system of firing shots in the mine that will reduce to a minimum the chance ignition of a gas feeder being undiscovered; or the occurence of windy or blownout shots, or local gas or dust explosions. Load out all fine coal and slack, and forbid its being thrown back in the waste. Ventilate all abandoned places, voids and falls; examine these regularly for gas; report and remove promptly all dangers. As nearly as practicable, make all air bridges, stables, pump rooms, engine rooms, tool rooms and shanties fireproof; and allow no oily waste thrown around carelessly. Have all electrical apparatus, wires and switchboards properly installed and inspected by a competent electrician. Absolute and thorough discipline is essential in all mine operations, and will prove the greatest safeguard against fires.

(b) Notify the men by phone, sending, also, trustworthy men to direct the escape of the workmen by the safest possible route. Without a plan of the mine showing the location of the fire, circulation of air and avenues of escape, it is impossible to indicate in more than a general way what course should be followed. The character of the fire and its environment must determine the details of the plan of action. There are always, however, two chief considerations; namely, (1) to get water on the fire (assuming it is a conflagration), and (2) to so control the circulation as to smother the fire, as far as this is possible at the time, and prevent the smoke and gases from passing into the mine.



Showing Arrangement of Shaft Bottom

Each case will present a different proposition that must be treated accordingly. The accompanying diagram represents a common arrangement in many mines. Assume, in this case, a fire has gained some headway on the shaft bottom, about 25 yd. from the foot of the shaft, and 50,000 cu.ft. per min. is passing this point and entering the mine. A brief reflection will show that the 250 men working on this side of the mine have but slight chance of escape unless there are cool heads at the bottom of the shaft. Some one says, "Slow down the fan or stop it entirely." In some cases, this would be necessary; especially, if there is no other way of reducing the current passing the fire, which, unless reduced, would soon convert the place into a furnace.

In the present case, the best plan would be to short-circuit a portion of the air, by setting partly open the separation doors close to the shaft. These are the double doors marked *aa* in the figure. To open these doors wide might prove as dangerous and fatal as the full air current, because of the deadly carbon monoxide that would then be formed by the fire, and which is not only extremely poisonous, but increases the explosive condition of the mine air. It is important to control the amount of air passing the fire by the regulation of these doors, so that the air will not fan the blaze and still keep the entry clear outby from the fire.

It would be a fatal mistake to set open either of the doors marked *bb*, on the cross-entries, as this would increase the draft on the fire, burn out the overcasts at the mouths of these entries and absolutely cut off the escape of the men.

The above is about as bad a case as could well occur in so-called safe mining. It shows the importance of providing a number of avenues of escape, as well as separation doors close to the bottom of the shaft, for the better control of the current. The advantage of this method over that of slowing or stopping the fan is that it keeps the escapeways and upcast clearer and safer; and reduces the formation of CO, by the fire, to a minimum, while practically cutting off the draft from fanning the blaze, and providing fresh air for the fire fighters.

Pressure In a Slope Pipe Line

Ques.—A pipe line in a mine slope has an area of 180 sq.in. and is 3000 ft. long; the slope has a grade of 1 in 10 ft. What is the pressure per square inch at the bottom of the pipe when the latter is full of water?

Ans.—If the slope rises 1 ft. vertical height for each 10 ft. measured on the pitch, the total rise is $3000 \div 10 = 300$ ft.; and the static pressure is then

$300 \times 0.434 = 130.2$ *lb. per sq.in.*

This is the pressure when the pump is not working. When the pump is acting there will be an additional pressure, due to the friction of the water flowing through the pipe. This will depend on the size of the pipe and the quantity of water discharged.

For the Betterment of Living Conditions in Mining Communities

Some Remarks on Safety in Mines

By S. J. Phillips*

Education should always precede discipline. It is wrong to discharge or suspend a miner for pushing a light cartridge into a drillhole, if that miner does not know the danger which may result from such an action. When a boy or man knows exactly what he should do and does not do it, he forfeits his right to hold his job, and the best thing that a foreman can do for the man and his family is to put him out of the mine before he kills or injures himself or his fellow workmen. This act is as humane as taking a razor from the hands of a baby. You might say that it is not right to take the bread out of a man's mouth. We all are opposed to doing that, and it would be much easier for the foreman, I admit, to permit the miner to go on a little longer violating the law and the rules of the company for which he worked, but it is because such a lack of discipline is endured for just a little longer, that so many are killed and many more are injured. Let your sympathy exhibit itself in the direction in which it will do the most good. It is better to send a man home to his family without his job than without his life. It is better to see him return before noon than to meet the undertaker at the door.

I go into places quite frequently and find the miner's powder box open. When I question the miner as to the length of his experience in the mine, the answer sometimes is, "ten years." What is the natural conclusion? That a miner who has been disregarding the orders of the assistant foreman, the foreman, the company's inspector, and the State mine inspector for ten years is hardly a fit man to work in the mine. This very act shows a man's mental attitude toward any order which is issued in the interest of safety, and as this is one of the easiest orders to obey, and as he does not obey this, it is evident that he is unlikely to obey any.

I am thoroughly in accord with the order issued by the Delaware, Lackawanna & Western Railroad Co. in all its collieries, relative to shots which have apparently failed to explode. The rule is that: If a squib-fired shot fails to ignite, the miner and his laborer must go home for the rest of the day. Some operators will say that this rule will be sure to lower the tonnage wherever enforced. District No. 1 of the Delaware, Lackawanna & Western Railroad Company, Coal Mining Department, increased its output last year where this rule was in force, and, furthermore, accidents were reduced one-half in the same district and not one of these occurred from a delayed fire. When miners are asked to stay 15 min. before returning to work because a shot has misfired, they are apt to overestimate the time during which they have waited or they deliberately break the rule. This is especially the case where there is little coal ready to load and an empty car on its way to the room. The more stringent regulation obviously prevents the miner from miscalculating or deliberately reducing the time limit.

*Mine inspector, third anthracite inspection district.

Note—Abstract of article read before the First Aid Association of Pennsylvania Coal Co., at Dunmore, Penn.

Loading the Mine Foreman

By Sim Reynolds* and W. H. Reynolds

Whenever a discussion arises as to the fatalities in mines, the suggestion is made that some new burden shall be loaded on the mine foreman. It would seem better to seek immunity from accidents in the rank and file, instead of endeavoring to secure a reform entirely through the efforts of an official, who is already hard pressed and harassed under the many onerous requirements which have been placed upon him.

The fact that he has come up from the ranks, as he almost invariably has, shows that he possesses an energy and ability unusual in his class, but does not imply that he is a wonder-worker, and that there is no limit to the services which he can perform. Quite often this most worried unit in the conglomerate mass of mine workers has to shoulder faults for which other parties are to blame.

Conditions at any given mine may be, and frequently are, adverse by nature, and he may be confronted moreover with problems which are the direct or indirect outgrowth of a long continued faulty method of mining, and yet, despite these severe conditions, the blame is placed on him by the state and by his employers when untoward things happen.

But to lay the blame in the wrong place does not cure it. One wrong added to another wrong never made that wrong right. We must look to other sources beside this for a reduction in the great number of fatalities. We must instil the idea of the supremacy of the law in the minds of other men than the fireboss and mine foreman. This view of the condition of affairs is not new, but it is necessary that it should be instilled in everybody around the mine. At the time of an accident, the hue and cry is always that the mine foreman has neglected his duties, whereas there are probably two to four hundred men who are all vitally interested in the safety of the mine, any one of whom may be the real cause of the accident.

As President Taft recently emphasized on Forbes Field:

> This loss of life (20,000 killed outright and 70,000 injured in the coal mines during the last 20 years) must be brought home to the miner himself. We have certain defects—and one of them is a feeling of security that we are not going to get hurt. We must overcome that notion, and we must take more precautions to save life. This requires discipline, instruction and experience. We must enforce these ideas so that the miners themselves may save themselves by strict attention to the instructions, which must be given in turn by government and state.

Practically every man who is qualified to speak publicly on the matter by virtue of his experience and study of mining conditions, evinces the same belief as to the means which will ultimately have to be employed to bring the human element up to the same efficient standing already gained by the mechanical end of mining. First educate the miner to an understanding of the dangers of his employment; second, exert at all times the strictest possible discipline; third, secure immediate action in such criminal proceedings as arise out of the enforcement of the law.

In his speech at Pittsburg, the President, in my opinion, hit the nail of difficulty more squarely on the head than has been done by any man in or near his eminent position, perhaps touching the "sore spot" more closely than he himself knew when he concluded with the words: "We must stamp out the spirit of carelessness—the happy-go-lucky idea which I fear prevails among American citizens generally," and had it not been for the inherent courtesy of a gentleman toward his auditors of every station in life, the chief magistrate might well have added: "and the mining part of our population in particular."

*Pittsburg-Buffalo Coal Co., Marianna, Penn.

Coal Situation in the Philippines

By Monroe Woolley*

The Philippines have much good coal, yet but little is mined. The large consumption is met by Australian and Japanese imports. There is room for developments in Polillo, Cebu, Mindoro and Mindanao.

Area considered, there is perhaps no country in the world possessing greater or better fields of coal than the Philippine Islands. Moreover, there is no country known to be so rich in coal deposits where so little coal is mined.

During the American occupation, extending now over a decade, many millions of dollars have been spent abroad, chiefly in Japan and Australia, for the island coal supply. A comparatively small amount of fuel for domestic purposes is required in the archipelago for the simple reason that in the tropics fires are needed in the home for cooking purposes only. There are but two or three cities in the whole group of islands where families may buy coal from regular coal yards. One of these is Manila, and there the price is almost prohibitive for the average citizen.

But enormous quantities of coal are nevertheless consumed in the islands annually. The military establishment uses many thousands of tons in operating its numerous ice and condensing plants and in coaling the many steam vessels comprising the inter-island transport fleet. At every garrison an ice and condensing plant is maintained for the comfort of the command, making in all possibly half a hundred such institutions, consuming anywhere from a ton to several tons daily. In addition to the great amount of coal consumed by the inter-island fleet, the huge trans-Pacific transports coal either in Manila or in Japan for the return trip home each month.

Import Coal

Nearly all this great amount, especially for the consumption on land and for the inter-island fleet, has for some years been purchased in Australia. In fact, the contract was so often awarded to Australian companies that an investigation was conducted by the military commander, in Manila, in which one of our diplomatic agents in the land of the kangaroo figured to some extent. One of the Government contractors was quoted as saying that he had the military contract "cinched" so long as Australia wanted it. This remark precipitated the inquiry.

Japan has been lucky most of the time in holding the contract to coal the trans-Pacific vessels for the return journey to 'Frisco, the Mitsui Company, in Nagasaki, performing this service.

Besides all these channels for consumption there is the big demand made by the civil authorities. The civil government owns an ice and cold storage plant in Manila, which is probably as large as any in the world. It consumes enormous amounts of coal daily. Then, too, the civil government maintains a coast guard fleet equal in size to the military's transport fleet, which also has to be coaled regularly. Much of the navy's coal, destined to be used by the Asiatic and Philippine squadrons, and by the navy yards in the Philippines, is supplied from Asiatic mines.

The Batan Coal Area

From all this it would appear that the government should make haste to develop the fields in the islands, but so far big coal furnishing contracts are still going to Australia and Japan. Soon after American occupation of the islands, the military authorities staked out coal claims on the western half of Batan Island, in the Gulf of Albay, Southern Luzon, and the President set aside the land by executive order as a military reservation. Meantime, some Americans resident in that part of the archipelago, saw the advantage of staking out claims on the eastern half of Batan, the entire island being covered with coal.

The government lost no time, owing to the crying need for a home-produced coal, in developing its claims, sending an engineer officer and a detachment of men down to experiment. Many tons were taken out and trial tests were made on government vessels plying between the gulf and Manila. The coal at that early date was found to be equal to and sometimes superior to the Japanese product for steaming purposes. Scientific tests of the fuel were made in the laboratories of the bureau of science, at Manila and gave encouraging results.

However, some two or three years later operations were discontinued, largely on account of a lack of funds for experimental purposes. The government claims then remained closed for some two or three years, when an energetic, military official in Manila finally secured additional funds by act of congress, and prepared to reopen the mines on a larger scale.

Batan Coal Makes Good Showing

The officer who had charge of the work during the first attempt was ordered back from Washington to resume operations, and brought with him modern apparatus and a large corps of expert miners from the United States. The work had barely begun, however, when friction arose between the civilian mining expert and the military officials, ending in the discharge of the expert. Following this, other officers were detailed in charge of the work, which went on enthusiastically for some months. The Manila press heralded almost daily the success of the project, and all the Philippines were joyful at the prospects of an adequate fuel supply. Finally a cargo of Batan coal from the government mines was placed aboard the trans-Pacific transport Dix, the largest vessel in the military service, for a trial test in steaming to the home port in Seattle. It is not known what the official report of this test had to say of the product, but shortly afterward the Batan government claims were again closed, and have since so remained. The engine room employees of the Dix, as made known through the Seattle papers, were favorably impressed with the coal, the ship entering port on schedule time.

In the meantime the pioneers owning the claims on the eastern half of Batan, while handicapped at times for capital, have been mining coal steadily, having formed a stock company, the shares of which are increasing in price. This company has been for some time shipping coal to Manila for the local markets and is supplying quite a number of inter-island commercial vessels with coal for steaming purposes. Only a short time ago the flourishing condition of the company was attested when it purchased for $50,000, the Steamer Yuengsang, which was formerly in the China-Philippine trade. This ship is used by the company in delivering its product throughout the islands.

Other Coal Deposits

Polillo Island, much larger than Batan and which lies to the northward of the Government claims, is said to be rich in coal. A number of Americans have claims here, but so far as known little development work has as yet been undertaken. Perhaps lack of capital prevents, perhaps there is some other reason.

There are one or two small mines in the vicinity of the flourishing port of Cebu, but the output is inconsiderable. It is also believed that the large islands of Mindoro and Mindanao, both rich in all manner of mineral deposits, are also rich in coal, and some private parties are endeavoring to locate mines.

*Fort Casey, Island County, Washington.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

The new bill, prepared by Judge Knapp, of the Commerce Court, and Commissioner Charles P. Neill, of the Bureau of Labor, to take the place of the Lee bill, for extending the application of the Erdman Act to coal-mining disputes, has just been placed in the hands of the subcommittee of the House interstate commerce committee. The terms of this proposed bill have not heretofore been made known, but the measure is proving of very considerable interest. Salient features of the proposed measure are as follows:

The provisions of this act shall apply to any railroad corporation engaged in interstate commerce and to its employees, and to any person, firm, or corporation engaged in the mining of coal which enters into interstate commerce, and to their employees.

Whenever a controversy concerning wages, hours of labor, or other conditions of employment shall arise between employer and employees subject to this act, interrupting or threatening to interrupt the business of said employer, to the serious detriment of the public interest, either party to such controversy may apply to the commission of media- and conciliation created by this act and invoke its services for the purpose of bringing about an amicable adjustment of the controversy; and upon the request of either party the said commission shall, with all practicable expedition, put itself in communication with the parties to such controversy and shall use its best efforts, by mediation and conciliation, to bring them to an agreement.

Whenever a controversy shall arise between employer and employees subject to this act, which cannot be settled through mediation and conciliation in the manner provided in the preceding section, such controversy may be submitted to the arbitration of a board of three or of five persons, as the parties to the controversy may elect, which board may be chosen in the following manner: The employer or employers and the labor organization or organizations, parties, respectively, to the agreement to arbitrate, shall each name one arbitrator. The two arbitrators thus chosen shall name the one or the three arbitrators, according, as the agreement to arbitrate provides for a board of three or five, but in the event of their failure to name the three arbitrators required, days after their first meeting or to name the thre arbitrators required, when the agreement provided for a board of five, within ten days after their first meeting, the third arbitrator or the three arbitrators, or such of the three as have not been named within the time herein prescribed, shall be named by the commission of mediation and conciliation.

It is doubtful whether any report on this subject will be rendered at the current session of Congress, but those who have been supporting the bill are still expressing a determination to press its adoption.

Suspension of Duties on Coal

Senator Watson, of West Virginia, himself a large coal operator, has offered the following amendment to the pending metal schedule in the Senate, it being his view that the provision would serve to meet an emergency like that which existed at the time of the coal strike in 1902, when Congress finally suspended the duties on coal for a year.

The President is hereby authorized, in any case of emergency, to suspend the collection of customs duties on any article included for taxation in the tariff law in effect on the day the President issues his proclamation suspending the collection of duty on any article, so that such article may be imported free of duty for not exceeding the period of one year. When the President decides to suspend the collection of duties on any article, he shall issue his proclamation to that effect. Such suspension of the collection of customs duties for the period named by the President in his proclamation shall take effect on the day following the issuing of said proclamation, and shall continue for the period named.

Alabama

Birmingham—If the coal production of Alabama for the remainder of the year holds up to the pace set during the first four months, the coal output for 1912 will break all previous records and will come close to being 19 or 20 million tons. According to the chief mine inspector, the output for the first four months of the year is far ahead of 1910, the banner year in the history of the state, when the production exceeded 16,000,000 tons.

The Tennessee Coal, Iron & R.R. Co. is blowing in the third battery of 70 Koppers ovens at its new byproduct coking plant, at Corey, Ala., and is abandoning its bee-hive ovens at Pratt City and Pratt No. 1 shaft. As the new byproduct ovens get up to capacity and into smooth running order, the bee-hive ovens, at Pratt Nos. 3, 4 and 5, will be dropped out of commission, leaving only those at Johns in blast. These last will be displaced also, as soon as the fourth and last battery of Koppers ovens at Corey is finished, during the next few months.

Colorado

Steamboat Springs—It is announced that the Moffat Coal Co. will at once start work on opening up its anthracite coal holdings. The entire 1000 acres, controlled by the company, are to be thoroughly prospected and sinking started.

Illinois

Benld—One man was fatally injured and four others received serious wounds in a revolver battle between two mine crews, near here, May 10. Half of the men were employed in mine No. 2 of the Superior Coal Co., which has three pits at Benld; the other half composed the crew of mine No. 3. The Benld local had been informed by state officials of the union that the men might return to work pending a referendum vote, and No. 1 and No. 3 crews, whose members reside at Gillespie, a mile and a half north of Benld, voted to go to work. Crew No. 2, composed of Benld men, voted to stay out. When crew No. 3 was on its way to work it was met by crew No. 2, with orders to turn back. Both sides drew revolvers and started firing into the air, but as the situation grew more serious, the No. 3 crew fired a volley at their opponents, hitting the five men. Both crews then returned to their homes.

Springfield—The plant of the Spaulding coal mine, north of Riverton, near here, was partially destroyed by fire, May 7. The top works were set on fire, it is said, by sparks from a railroad locomotive. The mine was to have resumed operations the day following, after being shut down for some time. Nine men were at work, preparing for the resumption of operations. They escaped through the Riverton Mine No. 1, which is connected with the Spaulding mine. The Illinois National Bank, of this city, owns the mine. The loss is about $50,000.

The referendum vote on the new wage contract, taken by the Illinois miners, May 7, favored its acceptance by a majority of over 13,000.

Peoria—The mine of the Wolschlag Coöperative Coal Co., south of Bartonville, has been taken over by Messrs. Ditewig and McElwee, who already own and operate, near Farmington, two of the largest mines in Peoria County. The Wolschlag property is located near the lines of the Peoria Ry. Terminal Co., and will also be on the lines of the Chicago & North Western, when its new branch to the south is completed. The

capacity of the mine will at once be increased to 1500 tons per day, and it is reported that the entire output has been sold for a period of two years.

Chicago—Increases in freight rates on soft coal from Illinois mines to destinations in Kansas and Nebraska have been suspended by the Interstate Commerce Commission from May 11 to Nov. 11. The advances, amounting to approximately 12 per cent., are now under investigation by the commission.

Indiana

Terre Haute—After modifying their demands to the operators, eliminating many of the requests included in the first report of the scale committee, the delegates to the convention of district No. 11, United Mine Workers, voted unanimously to adopt the report of the policy committee, which is practically a declaration of a strike in the Indiana bituminous coal field. The report of the committee contains provisions for a strike benefit to the men who are in actual need. The mine workers instructed the district officers to attempt to sign up the independent operators in the Indiana bituminous field, said to number about 25 per cent. of the operators in Indiana.

It was decided at a meeting of the coal operators, May 8, to obtain coal from other states and supply it to their customers at Indiana prices, pending the outcome of the trouble with the miners. The operators say that they can buy coal in Kentucky and West Virginia at prices which will enable them to deliver it to customers without loss to themselves. This coal is mined by nonunion men. No men will be imported to work in the mines here, it is said, and, therefore, no violence is expected. It has been the contention of the operators that when the Cleveland agreement was signed at Indianapolis, it was virtually promised that the men would return to work pending negotiations on the details of the state contract.

Sullivan—Following the purchase by the Chicago and Eastern Illinois R.R. of 16 coal mines in Indiana and Illinois, including a tract of 3000 acres in Sullivan County, Ind., the announcement is made that a mine is to be sunk at once on a tract lying a half mile east of Paxton. This is to be done by the J. Wooley Coal Co. of Evansville, to which a part of the 3000 acres purchased by the C. & E. I. has already been leased. Work on the sinking of the new shaft will be begun at once, and development is promised of a field heretofore untried, but said to be rich with coal. The tract was sold by the West Jackson Hill Coal Mining Co. and this company still owns 4000 acres in the Paxton field.

Bicknell—The Monon Railroad is preparing to extend its line from Wallace Station to Bicknell. The company has recently purchased 6300 acres of coal lands south of the Little Giant mine, between Linton and Bicknell, and the line will extend through this land. The positive assurance of this extension has renewed activity all along the proposed line, and doubtless new mines will be sunk and mining operations increased as soon as the strike situation is relieved.

Kentucky

Louisville—District No. 23 of the United Mine Workers, comprising the employees of the union mines of western Kentucky, has voted to return to work pending the settlement of slight differences over the wage scale, which will be arbitrated. The vote was 1850 to 425 in favor of resuming work, and the mines have started up again.

The Harlan Coal Mining Co., of Louisville, which is to open three mines on the extension of the Louisville & Nashville R.R. to Harlan County, has let contracts for all of the equipment required, and this will be delivered in the immediate future, as the company plans to start operations at once. By the time the company is ready to mine coal, the railroad extension will have been completed to its plant. The proposed output is to be 2000 tons a day.

Madisonville—A French syndicate is reported to have purchased 1000 acres of coal lands in Hopkins County, near Madisonville. Negotiations are pending for 4000 acres additional. The property is off the railroad, but an extension of the Kentucky Midland R.R. may be built to reach it if mining operations are begun.

Pikeville—The Pond Creek Coal Co. is actively engaged in driving entries, building houses and preparing in general for the development of its coal properties. The company will have an outlet through the new Williamson & Pond River R.R., a Norfolk & Western line, which is to be built from Williamson, W. Va., up Pond Creek to the holdings of the company.

Missouri

Kansas City—The subcommittees of operators and miners of the Southwestern field, after a two-weeks conference at which they failed to reach an agreement, reconvened here, May 8, to resume negotiations for a 2-year contract.

Ohio

Zanesville—The majority of the coal mines in this vicinity are again in operation. A meeting was held in Cambridge, May 9, to adjust details of the contract for the Cambridge district and a similar meeting for the Crooksville district will be held here later this month.

The Cambridge Coal Co. has constructed a manway at its workings east of Byesville on what is known as the narrows. This is 12x14 ft. in section and about 80 ft. deep. A winding stairway affords a ready means of egress in case of fire or other accidents in the mines.

Crooksville—Three miners were entombed in Keystone Mine No. 1 for several hours, May 6, as the result of a cave-in. One was rescued with difficulty and his injuries seemed likely to prove fatal. The other two were only slightly injured.

St. Clairsville—One of the largest damage suits in the history of the local court was put on record, May 6, when William Fulton entered suit against the Youghiogheny & Ohio Coal Co., asking $65,000 damages for injuries which he received in the mine of the defendant and which injuries he alleges were due to the negligence of the company.

Massillon—The conference between miners and operators of subdistrict No. 3, district No. 6, United Mine Workers, reached an agreement, May 4, whereby a slight increase of wages was granted to engineers and bucketmen, engaged in sinking shafts, and the wages of other workmen were fixed in accordance with the Cleveland wage-scale agreement. The operators advanced the cost of coal to miners from $1.90 to $2.

Oregon

Portland—That Oregon, some day not so very distant, will mine coal on a large scale is indicated by the activity of men interested in coal properties in various parts of the state. It is reported that large coal deposits in eastern Oregon will be opened up as soon as arrangements can be made for transporting the coal, and as it would require only about 50 miles of railroad extension to do this, it is held that it will not be long before development work is under way. The coal is said to be of good quality.

Pennsylvania

Bituminous

Washington—E. T. Kurtz, receiver of the Washington County Coal Co., announced, May 7, that he had sold the company's property to Samuel Hollis, of Pittsburg. The price paid was $300,000. All real estate, a railroad line and an operating mine are included.

James S. Campbell, of Mt. Pleasant township, on May 8, sold to Virgil McDowell, of Midway, said to represent the Wabash Coal Co., a tract of 335 acres of coal land. The land, which adjoins 800 acres owned by the coal company and lies along the line of the Wabash railroad, was sold at $100 an acre. It is bordered on one side by the property of the Wabash Coal Co. and on the other side by holdings of the Pittsburg Coal Co. It is understood that the acreage of the Wabash company will soon be developed and a spur run from the Atlas mines into this new territory.

An important coal deal was closed here, May 4, when notices of acceptance were served, whereby H. L. Duncan, of Pittsburg, representing a syndicate of Pittsburg capitalists, took over more than 5000 acres of coal land, located in Washington County, the average option price being $115 an acre. The tract, comprising the Pittsburg seam of coal, lies in Cross Creek, Jefferson and Smith townships, extending northwestward from Cross Creek village, almost to Dinsmore and Hanlin on the Panhandle railroad. The coal block is unusually accessible to railroads, having the Wabash along the southern border and extending on the north to the Pennsylvania lines.

Clearfield—Tellers have completed the count of votes on the ratification of the new wage contract for the bituminous miners of district No. 2, United Mine Workers, and find that 22,325 were for acceptance, and 5245 for rejection.

Indiana—The Buffalo, Rochester & Pittsburg Coal & Iron Co. has started work on another operation in this county, about two miles from Jacksonville, where it is expected coal will be taken out before the coming winter. The tipple will have a capacity of several thousand tons per day.

Within the past couple of weeks contractors and others interested have gone over the plans for the extension of the railroad from above Idamar to what is commonly known as the Lowry coal, three miles east of Marion Center, and the indications are that the road will be built in the near future.

Pittsburg—The Interstate Commerce Commission has set May 16 for the hearing of arguments in the petition of John W. Boileau and coal operators of the Pittsburg district who ask for a hearing in their case against the Pittsburg & Lake Erie R.R. and other carriers. The petitioners, after a hard fight, won a reduction of 10c. a ton on the coal rate of 88c. from the Pittsburg field to Ashtabula Harbor. The action of certain railroads in reducing rates from competing fields, it is asserted, has nullified the commission's order so far as the Pittsburg operators are concerned.

Anthracite

Scranton—Riotous demonstrations have been taking place recently in nearly all sections of the anthracite field. Following the trouble at the Dickson shaft of the Delaware & Hudson Co., on May 7, a similar demonstration took place at the Leggetts Creek and Von Storch collieries in North Scranton on May 9. The Cayuga breaker of the D. L. & W. Co. was the scene of another riot in the morning of May 10 when a crowd of several hundred men, women and boys assembled to keep men from going to work. The police were attacked and fired on the mob, wounding several men. A number of arrests were made. At Olyphant, on May 11, a conflict took place between state police and a crowd of rioters who had assembled near the No. 1 breaker of the D. & H. Co. A 14-year old boy, on the outskirts of the fray, was shot and it was thought would die.

Wilkes-Barre—Angered at the number of men employed doing repair work at the collieries in this region, small armies of idle men attacked a number of the workers May 9. At the Nottingham Colliery, at Plymouth, a crowd of 500 men and boys menaced the workmen and compelled them to return to their homes. Repairmen, pumpmen, firemen and engineers were held up at the Delaware Colliery, at Hudson. At a washery in Luzerne borough, the men at work were driven from the place by a crowd of 400 men, women and boys, who used sticks and stones. Hundreds of idle mine workers have left here recently for the West Virginia bituminous region, although officials of the United Mine Workers have tried to persuade them not to go.

The tridistrict convention of anthracite mine workers met here May 14 with 407 delegates in attendance. The foreign element proved to be in a majority and indications pointed to heated discussion.

Pottsville—In a clash between a detail of seven state police and foreign mine workers at Minersville on May 8, three men were shot, two fatally, and a woman injured. The police were escorting Superintendent George W. Keiser and several repairmen to the Pine Hill colliery. Attacks on men going to work at the mines have been general throughout the lower end of the anthracite field and several attempts have been made to dynamite railroad tracks and trains. The companies have suspended all work except that absolutely necessary to keep the mines in order.

Hazleton—Local unions on May 10 adopted resolutions asking that all repair work at the mines be discontinued but agreeing to permit engineers, firemen and pump runners to remain on duty.

Washington

Seattle—Paul Bockmier, of Palouse, Wash., has found a 6-ft. seam of coal within six miles of that town. A tunnel has been driven 85 ft. into the bluff along the Palouse River, and when in a distance of 50 ft., exceptionally good samples were taken out. The work of prospecting is being done by some individual members of the Palouse Coal & Oil Co. The surface croppings are of poor quality, but the coal evidently becomes better at a slight depth and is believed to be a good fuel.

Word was received here recently from the Mare Island navy yard that the cruiser "Maryland," which will arrive about May 15 for repairs, will be used to make further tests of the Pacific Coast coals. She will load with Western coal for a cruise to Alaska.

West Virginia

Welch—The Jed Coal & Coke Co., with a mine near here at which an explosion occurred recently, killing 81 men, has been placed in the hands of A. H. Storrs as receiver. This action of the court was taken at the request of Mr. Storrs, who was recently elected president of the company, and was opposed by William Leckie, a stockholder and formerly general manager. The company is capitalized at $600,000 and has never paid a dividend, the earnings having been used in the development of the property. Most of the stock is held by people in Pennsylvania.

Holden—The United States Coal & Oil Co. is opening up a large amount of new territory in this state and in Kentucky.

Charleston—The West Virginia-Pittsburg Coal Co., which has operations in the Cross Creek district of Brooke County, in the northern panhandle, has increased its authorized capital from $10,000 to $1,500,000.

Nine thousand miners in the Kanawha district, who had been idle since the first of April, returned to work, May 7, following a settlement of the wage-scale dispute. The men will receive an advance in wages equal to half of that provided for by the Cleveland joint conference. Miners in the Paint Creek section still remain on strike.

About a score of the mines in the Kanawha district have not yet resumed operations since the agreement of a week or more ago. The operators who refused to sign claim they have been operating their mines at a loss for several years, and that to pay the increase would only add that much more to the loss. In consequence the mines have been closed indefinitely.

The old Nuttallburg Coal Co.'s property, recently purchased by W. E. Deegans, of Fayette County, under a decree of the federal court, is to be operated under the name of the Nuttallburg Smokeless Fuel Co., just chartered by Mr. Deegans and others. The new company is capitalized at $125,000.

Canada

British Columbia—The Corbin Coal & Coke Co., Ltd., which is operating a mine in Crows Nest Pass, has filed amended articles of incorporation, increasing its capital from $2,000,000 to $10,000,000. It is understood that the increase of capital is due to the fact that the company is securing possession of large additional areas of coal land. D. C. Corbin, of Spokane, is the principal stockholder.

Personals

J. M. Fitzgerald, president of the Davis Coal & Coke Co., recently made a trip of inspection to the company's mines, at Thomas, W. Va.

C. F. Brenn, chief engineer for the coal-mining operations of the Chicago, Milwaukee & Puget Sound Ry., recently returned from a month's business trip to Montana.

Henry M. Payne has become associated with Stephen T. Williams & Staff, of New York, and will leave the latter part of this month for the Yukon and Klondike gold fields, returning late in the summer.

Harry Thomas has been appointed general superintendent of the O'Gara Coal Co.'s properties, in Illinois, Indiana, Ohio and West Virginia, with headquarters at Harrisburg, Ill. Edward Gent and D. B. McGehee have been appointed assistants to the general superintendent.

Edgar Kudlich, formerly general superintendent for Coxe Brothers & Co., Inc., and recently division engineer for the Lehigh Valley Coal Co., at Hazleton, Penn., has resigned from the Lehigh Valley company to accept a similar position with the Lehigh Coal & Navigation Co., at Lansford, Penn.

George C. Atkinson has been elected president of the St. Bernard Mining Co., of Warlington, Ky., succeeding the late John B. Atkinson, who died about six months ago. Frank D. Rash has been chosen vice-president and general manager, and Dan M. Evans, secretary and treasurer of the company.

The senior and junior students in the department of mining engineering of the University of Illinois, recently visited the Illinois Steel Co.'s plant, at Joliet, the mines, zinc works and cement plants in the La Salle district of Illinois, and a number of manufacturing plants in Chicago, where mining machinery is made, also the accounting offices of a number of the larger mining companies, having headquarters in Chicago.

The following changes have been made in the coal-mines division of the Tennessee Coal, Iron & R.R. Co., Birmingham, Ala., effective May 1. C. G. Owen, acting chief engineer, has been appointed chief engineer. W. H. Sterling, superintendent of bee-hive ovens, has been appointed superintendent of Pratt No. 12 mine, with headquarters at Docena, Ala., succeeding H. McKean Conner, resigned. L. V. Harvell, until recently division engineer of the Blue Creek division, has been appointed assistant superintendent of that division, with headquarters at Johns, Ala., succeeding John A. Jordan. George W. Postell, until a few months ago division engineer of Pratt No. 2 division, has been reinstated in that position, succeeding John A. Ridgney, detailed on special work.

Obituary

Joseph E. Ball, for a number of years a sales agent of the Delaware, Lackawanna & Western Coal Co., at Buffalo, N. Y., died recently at his home in that city. Mr. Ball was 61 years of age and well known in connection with the Lake trade.

Frank J. Bergs, vice-president and general manager of the Berry-Bergs Coal Co., of St. Louis, was killed recently, when an automobile, which he was driving, was struck by a Missouri Pacific train. Mr. Bergs was 46 years of age and one of the most prominent and popular coal men west of the Mississippi River.

Construction News

Harlan, Ky.—The Wilhoit Coal Co. is building a power plant and will install electric coal-cutting machines.

Marion, Ill.—The West Virginia Coal Co. is planning to build here a large coal storage and rescreening plant.

Washington, Penn.—The Pittsburg-Buffalo Co. has announced that it will install 500 additional coke ovens at its Marianna plant.

Superior, Wis.—The Pittsburg Coal Co. has announced that $750,000 has been appropriated to be used in making extensive improvements to its local dock.

Brownsville, Penn.—The Lilly Coal & Coke Co. has started construction work on its new plant at West Brownsville, to cost $1,000,000. A steel tipple will be erected.

Herrin, Ill.—It is reported that the Chicago-Herrin Coal Co. will make improvements to its surface plant and will erect storage pockets and screens for loading on two railroads.

Lansford, Penn.—The Lehigh Coal & Navigation Co. has decided to erect a large number of houses for the employees of its new colliery at Hauto, Penn., now under construction.

Cumberland Gap. Tenn.—The Eastern Kentucky Land Co. contemplates the development of coal property near here and will be in the market for machinery. Address Lewis Apperson, Mt. Sterling, Ky.

Red Ash, Ky.—The Proctor Coal Co., which will develop 6000 acres of coal land to a daily capacity of 2000 tons, has not yet fixed a date for opening machinery bids. Address Philip Francis, superintendent.

Indianna, Penn.—The Buffalo, Rochester & Pittsburg Coal & Iron Co. has started work on a new operation at Jacksonville. The Heyl & Patterson Co., Pittsburg, is reported to have the contract for a large new tipple.

Bay City, Mich.—The Central Coal Mining Co. has completed plans for building a large coal-handling dock on waterfront property recently purchased. Facilities will be installed for coaling vessels and receiving coal by water.

St. Paul, Minn.—The C. G. Hartin Coal Co. has purchased a large property on Dale St. and will build a coal-storage yard of 25,000 tons capacity. Elevators and rescreening plant will be installed. Immediate outlay on improvements to be $40,000.

Publications Received

INDUSTRIAL EDUCATION. The twenty-fifth annual report of the Commissioner of Labor. 822 pp., 6x9¼ in., cloth. Government Printing Office, Washington.

REVIEW OF LABOR LEGISLATION OF 1911. Bulletin No. 97 of the Bureau of Labor. By Lindley D. Clark. 622 pp., 6x9¼ in. Government Printing Office, Washington.

MINING CONDITIONS UNDER THE CITY OF SCRANTON, PENN. By William Griffith and Eli. T. Conner. Bulletin No. 25, Bureau of Mines. 90 pp., 6x9 in., illus., and case of 29 maps.

This bulletin is a publication of the report recently made by Messrs. Conner and Griffiths to the city of Scranton.

TESTS OF COLUMNS: AN INVESTIGATION OF THE VALUE OF CONCRETE AS REINFORCEMENT FOR STRUCTURAL STEEL COLUMNS. By Arthur N. Talbot and Arthur R. Lord. Bulletin No. 56, Engineering Experiment Station, University of Illinois, 25c. 44 pages, 6x9 in., 1 pl., illustrated.

This bulletin gives an account of a series of tests to determine the strength of a structural steel column of considerable strength having a filling of concrete. The tests show that this type of column, if properly made, is a reliable and efficient structural member, and that nearly all the strength of both steel and concrete is developed. The tests also show that up to the point of failure of the column, the fireproofing shell of concrete adheres tightly to the remainder of the column.

Hyatt Roller Bearing Co., Newark, N. J. Booklet. Twelve Progressive Mine Car Wheel Makers. 16 pp., 3⅜x6¼ in., illus. Twelve makes of mine car wheels, to which Hyatt roller bearings have been applied, are illustrated and described.

Industrial Notes

The Roberts & Schaefer Co., Chicago, Ill., announces that on account of the increase in the company's business during the past year it has decided to move into more commodius quarters, and after May 11 will be located in its new offices on the top floor of the McCormick Building, Chicago.

Walter B. Snow, publicity engineer, 170 Summer St., Boston, has increased his organization by the addition of Mr. Charles Mulligan, late of the editorial staff of the Brooklyn "Standard Union," and for a considerable period associated with the publicity department of the Western Electric Co.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

A more general resumption at the soft-coal mines, with a consequent increase in production, has resulted in another relapse in the bituminous market. The supplies accumulated in anticipation of the strike are still in evidence, and the trade has fully demonstrated its inability to absorb even a normal tonnage. Forced sales of demurrage coal are reported at some of the large distributing centers and quotations have fallen off generally in all parts of the country.

In anthracite the situation continues tight and supplies short; premiums are being offered on every hand and the market is in prime condition for a panic. Hard-coal shipments for April amounted to only 266,625 tons as compared with 6,596,687 tons for the month previous, and indications are that unless an agreement is effected in the meantime, the movement for the current month will show a still further decline. The shortage is most pronounced in the Northwest and it is probable that the season's shipments will not be sufficient to meet requirements as stocks are down to an unusually low point and this market, at the best, is only an overflow for the surplus tonnages.

Mining in the Pittsburg district is steadily increasing due largely to the Lake loading which is fairly heavy. Preparations are being made in Ohio at both the mines and on the railroads for the largest production on record. In West Virginia the movement has been quite free to tidewater but not as heavy as last month, while in the South prices are steady and the outlook good. Some contracting is being done in the Middle West but otherwise the trade is dull.

Boston, Mass.

There is little change in the Eastern market. Soft coal is certainly dull, and low prices are heard where cargoes are forced on buyers. There have been several instances of "sacrifice sales" during the past fortnight, and there is small encouragement in the outlook.

The Pennsylvania shippers are especially active in the pursuit of business on the low freights from Philadelphia, and sales from that direction and on Georges Creek are much heavier than on the West Virginia coals. At the Hampton Roads piers there is plenty of coal, although off-shore tonnage is still taking the largest proportion of it.

The anxiety over anthracite is again on the increase. Opinion here is about equally divided as to whether there will be a settlement at Wilkes-Barre, May 14, or a long strike. Meanwhile there are almost no hard-coal arrivals. Receipts are confined to odd lots of stock coal in egg and chestnut. Premiums are again heard, and conditions seem ripe for another "flurry."

Wholesale quotations are about as follows:

Clearfields, f.o.b. mines	$1.10@1.40
Clearfields, f.o.b. Philadelphia	2.35@2.60
Pocahontas, New River, f.o.b. Hampton Roads	2.70@2.80

New York

The anthracite trade in New York is practically at a standstill as no shipments are coming in and no sales being recorded. No great inconvenience has yet been reported but supplies are steadily disappearing and consumers are decidedly worried over the outlook. The large wholesalers are apportioning their remaining stocks among regular customers, and these represent the last remaining source of supply. There are more inquiries from buyers, particularly in the steam sizes for which there is quite an active demand.

Heavy tonnages of bituminous are arriving and this branch has suffered a further decline. There is little or no demand in the spot market, the movement being almost entirely on contract. The shortage of anthracite has had no effect on the soft-coal trade as yet. Prices on the lower grades have eased off still further, sales being reported during the week at as low as $2.40 f.o.b.; the higher grades, however, are holding steady, $3.05.

In anthracite, broken is about out of the market entirely, while the other sizes are selling at: Egg and stove $6; pea $5; buckwheat $3.25@3.50; rice $3@3.25; barley $2.25. The operating companies, however, continue to quote their regular winter circular as follows:

Broken	$4.50
Egg and stove	5.00
Chestnut	5.25
Pea	3.25
Buckwheat	2.75
Rice	2.25
Barley	1.75

Philadelphia, Penn.

The situation in this vicinity, while not in any way serious yet, is fast approaching that condition. The stocks of coal that various manufacturing establishments accumulated are slowly but surely disappearing, and while it is a fact that there is plenty of soft coal to take its place, at the same time any unusual call for this grade of fuel is bound to be followed by a substantial increase in price. Of course, this refers particularly to the steam sizes. What little stocks the operators had of these sizes are now quite low, and it will only be question of a few weeks at the most, when the situation will become decidedly uncomfortable.

As far as the domestic sizes are concerned, the supply now on hand is probably sufficient to cover all demands, which are light during the summer months. The findings at the meeting held last Tuesday will in a large measure dictate what disposition will be made of these stocks of domestic sizes. A refusal of the convention to abide by the terms of the settlement reached by the committees will more than likely result in a long strike, and a scramble among the householders for what coal they can get will undoubtedly follow, as was the case in 1902.

If mining is resumed by the first of June, it is more than likely that a reduction of prices will be made, as it is not felt that there will be any great demand for coal if the circular that was current through the winter, is still maintained. To create a market, the companies will have to reduce prices, as the apathetic condition of the market demands it.

Pittsburg, Penn.

Bituminous—Mining is increasing slightly in the district, but chiefly on account of heavier shipments in the Lake trade. Local demand is still extremely small, and operators probably have a better idea of the heavy stocks accumulated in anticipation of a long suspension than they had at the time they hastily made a settlement, on the eve of the expiration of the old agreement. Lake shipments are now fairly heavy, and a record year in Lake trade for the district is expected. It is not thought this will be due, however, to the reductions in rates the railroads made after the Interstate Commerce Commission's order to reduce the Pittsburg-Lake rate from 88 to 78c. per ton. Hardly enough had been done in the coal market to establish prices, and those first announced may still be quoted as follows: Mine-run and nut, $1.22½; ¾-in., $1.32½; 1¼-in., $1.47½; slack, 87½c., per ton at mine.

Connellsville Coke—Operators are asking higher prices for contract furnace coke for second-half shipment than was expected, the general asking price developed being $2.50, when consumers had questioned whether they would take an interest in a $2.25 quotation. No important business has yet been closed, but there are negotiations which will likely lead to results shortly. A small contract was recently made at $2.35, for the six months.

Sales of about 15,000 tons of prompt and May furnace coke have been made in the past 10 days, chiefly at $2.40, though a portion brought $2.45. We quote: Prompt furnace, $2.40@2.50; contract furnace (nominal), $2.40@2.50; prompt foundry, $2.75; contract foundry, $2.75@2.85.

The *Courier* reports production in the Connellsville and lower Connellsville region, in the week ending May 4, at 401,544 tons, an increase of 50 tons, and shipments at 4345 cars to Pittsburg, 6282 cars to points West and 1302 cars to points East, a total of 11,929 cars, or an increase of 47.

Baltimore, Md.

The continuation of the strike of the laborers and coal trimmers at the railroad piers in Baltimore had a detrimental effect on local market conditions during the past week. Prices dropped considerably, and many of the operators had the greatest difficulty in getting rid of the product in this city at even the lowest prices which have prevailed in the Baltimore market for months.

No coal has been handled at the Port Covington yards of the Western Maryland Railway Co., where hundreds of cars are waiting to be unloaded. Not a laborer would touch it, and the market would have been benefited just as much if it had not been shipped in. The situation is cleared up now, however, and loading has been resumed at approximately the normal rate.

At the Curtis Bay piers, of the Baltimore & Ohio, some coal was moved during the week, although the movement was retarded on account of a shortage of men. Among coal men it is believed that the worst is over, and that normal conditions at the railroad piers in Baltimore will prevail again soon.

There was a considerable movement by rail during the week, but practically all under contract. Very little spot business was reported. It developed a few days ago that the Uruguayan government had requested several coal operators to submit bids on a coal contract, the fuel to be used by the navy of that country. Should the companies here be successful, it is likely that Uruguay will be a large purchaser in this market in the very near future.

Buffalo, N. Y.

The bituminous trade is still very quiet and promises to remain so for a while, as the consumers who stocked up in March are still mostly well supplied. There was some expectation that the failure of the anthracite miners to go to work would immediately stiffen the bituminous prices, but the production is too large for that. It is estimated that the production is fully 40 per cent. more than consumption, and though quite a large part of the mines are either idle now or running part time, there is enough surplus to keep prices down.

A fairly good feature of the trade is the making of the annual contracts, for it was thought that the basis was hardly good enough for anything but transient sales. Some sellers are getting a better profit than last year. The trade generally goes on much as before, the new basis of reckoning not tending to help prices as a rule.

Quotations of bituminous remain nominally as before, $2.57½ for Pittsburg three-quarter, $2.47½ for mine-run and $2.25 for slack. Coke is again quiet at $4.75 for best Connellsville foundry. A mistake was made in putting coke prices too high.

Anthracite is plenty enough for local consumption, but there is none for the Lake and the Western rail-line trade. It is now believed to be impossible to produce enough to meet the demand from the upper-lake district, even if mining should begin at once.

The bituminous miners in the Allegheny Valley are very quiet, as there is not nearly enough work for them. Many have left the region and the same conditions are said to prevail in the South and West.

Cleveland, Ohio

There has been very little change in the situation in the past week. The demand for coal has not increased, as there still seems to be considerable on hand, which was obtained prior to the strike scare, and the manufacturers are not inclined to purchase at any price at the present time, owing to their being still well supplied.

Considerable coal has come in during the past week for the Lake trade, and slack seems to be a drug on the market. Quotations for slack are nominally $1.55 for No. 8, $1.45 for No. 6 and $1.65 for Pittsburg.

The general business in the steam trade does not look very encouraging up to the present time. There is, however, a feeling that there will be a large demand for the Lake trade; in fact it is generally believed this season will see the biggest Lake business that has been done for years.

Columbus, Ohio

Coal loading for the Lake trade has assumed considerable proportions during the past week. The greatest activity is in eastern Ohio, but a number of mines in the Hocking Valley are now busy. The Northwest docks are urging shipment during the suspension in the anthracite field, and for this reason a much larger tonnage will be moved than is usually the case with the first month of navigation. Lake demurrage rules go into effect the middle of the present month, and producers will be allowed only seven days after that date to release cars now loaded and awaiting bottoms.

Officials of the Hocking Valley Ry., which is affiliated with the Chesapeake & Ohio for West Virginia shipments, as well as being the chief outlet for the central Ohio territory, are preparing for the largest movement in the history of the road. They have announced that no Sunday excursions will be run this summer, as they will need that day for cleaning up and keeping the lines open.

Outside of the Lake trade, the market is very dull. Dealers are tardy about placing orders for stocking, and in this respect the present season is at least a month behind that of 1911. Salesmen report that most of the steam consumers have stocks held over from storage and cannot be interested. Tonnage on contracts has been cut to the minimum by railroads, public service plants and other large steam users.

Altogether there is a dearth of business that is keeping mines down to a day or two a week, where they are not idle altogether. This condition is looked upon as being temporary and one that will produce a stiff market within a very short time.

Prices remain practically unchanged, except for fine coal, which has dropped 10c. a ton during the past week. The prevailing figure on nut, pea and slack is 65c. As Lake production increases, this will go much lower, unless there is a concerted movement to hold it back from the market by track storage.

Hampton Roads, Va.

There has been little change in the market conditions at Hampton Roads during the past week. Coal is moving quite freely to tidewater ports although not in as great a volume as it did during the earlier part of the month. Prices are holding up well in spite of the approach of the summer season.

An especially noteworthy feature at Hampton Roads during last week was the 24-hour performance at the Virginian Ry. piers. The dumping over the Virginian piers on Monday last reached the enormous figure of 26,391 tons, or 551 cars of coal. Of these 303 cars were dumped during the day and 248 during

the night. While this entire tonnage was dumped within the 24-hour day, the actual dumping time was only 20 hours.

In the coal trade here the Virginian Ry. has been much congratulated on what is considered a wonderful performance, which goes well toward indicating the great future of Norfolk as a coal center.

Charleston, W. Va.

Although about one-half of the miners in the Kanawha district were out during the month of April, it proved to be the biggest month in shipments in the history of the district, which indicates what the mines could do if they were not handicapped by a shortage of cars and motive power. Between 8000 and 9000 miners were out in the Kanawha field during the month or for at least three of the four weeks.

The tonnage of the district for April, as shown by the Chesapeake & Ohio reports, was 973,730; that of the New River district was 739,100 tons, and the Kentucky district 151,390 tons. The tonnage for the entire Chesapeake & Ohio system in West Virginia for April was 1,864,220 tons, an increase of 356,130 tons over the month of March, when all the mines were in operation, but during which time there was a shortage of cars. This illustrates the conditions that the operators along the Chesapeake & Ohio have had to contend with.

Memphis, Tenn.

The wholesale situation so far as west Kentucky steam coal is concerned has been in pretty fair shape, as to price; the Henderson division of the L. & N. R.R. being a nonunion field, is the only western Kentucky coal that has been offered on the market for the past 40 days. However, this situation will change now, as the miners and operators have adjusted all their differences and the union field will go back to work immediately. This will have a tendency to cheapen the price of all grades of coal from this territory.

Prices now in effect are:

Mine-run	$0.80@0.90
No. 1 lump	1.25
No. 1 nut	1.10@1.25

The smaller screenings are very scarce and range from 40@80c. Alabama coal is unusually stiff in price for this season, as the bulk of the high-grade coals are sold up to Oct. 1. In the big veins domestic orders are in excess of the contracts for steam coal and consequently the Alabama situation is stiff at the present time.

The east Tennessee mines, which include the Jellico and Straight Creek seams, are getting better prices this season than last. Present quotations range from $1.65@2 for Block coal as against $1.50@1.80 last year. There is practically no coal in storage, either steam or domestic, throughout the Southern territory, and this will have a tendency to make good prices for the operator from now until winter.

Birmingham, Ala.

The coal market is maintaining a steady level in prices with satisfactory outlook. An improvement in the demand has been noted in textiles and railroads. Furnaces are not increasing their consumption as yet but the indications are that they will about the middle of the year. The market has been affected to some extent by the high waters on the Mississippi River and this is also offered as an explanation of the car shortage.

The commercial coke market is satisfactory. The policy of maintaining a fair level of prices in spite of the fluctuations in the Virginias has, it is believed, accrued to the benefit of the Alabama coke producers.

Some of the leading coal operators of the Birmingham district are investigating the possibilities of getting into the Cuban and South American markets, by reason of the coal shortage in England following the strike. Several shipments have been made and encouraging reports are being received from the consumers, indicating a willingness to continue. Alabama coal can be placed in the West Indies and South America at a saving to the consumer. The Alabama product, however, is so strikingly different from the Wales coal that it is no easy matter to introduce it.

Aside from the increased demand in some lines and the slight car shortage during the week, other factors entering into the market conditions are a labor shortage in some quarters and heavy rains causing some mine troubles.

Chicago

There will be no big improvement in the Chicago coal market until the beginning of September, according to observers of conditions here.

Small steam users and a few railroads, seeking to replenish their storage piles, create about the only demand which exists now. So far as Western coal is concerned, it may be said that domestic sells at $1.50 and steam at $1.25, at the mines. There is practically no demand for any kind of domestic coal. The supply of screenings is small and the price is correspondingly high. Screenings, mine-run and steam lump are selling around $2.10@2.25, f.o.b. Chicago. There has been little change in the smokeless-coal market, there being little or no demand for the product. It is generally believed that anthracite coal will not be available for the Western trade until late in the summer. The coke trade, generally, is dull.

Coke—Prices asked for coke are: Connellsville and Wise County, $4.75; byproduct, egg and stove, $4.55; byproduct, nut, $4.55; gas-house, $4.75.

Prevailing prices at Chicago are:

Sullivan County	
Domestic lump	$2.37
Egg	2.12
Steam lump	2.12
Screenings	2.12
Springfield	
Domestic lump	$2.32

Lump and egg	3.30@3.55

St. Louis, Mo.

There is practically no market in St. Louis for bituminous coal of any kind. The mines in the Standard field are gradually resuming work, but they are forcing the greater part of their tonnage on the railroad companies. Screenings are moving freest and are sold only with a proportionate amount of lump.

Carterville and Franklin County mines are gradually resuming, but the same condition prevails in that coal as with the Standard, with the exception that such as is moving, is going into the country.

There is nothing to indicate that the market will improve any in the very near future, but, on the other hand, it may gradually get worse as a greater tonnage is forced upon it. There is a limited amount of smokeless moving in, and the same applies to gas-house and byproduct coke.

The prevailing prices are:

Minneapolis—St. Paul

With the exception of making contracts on bituminous, business in this territory is extremely dull. There is hardly any domestic trade, and all the larger steam users are well stocked up, and will not be needing new supplies for another month or six weeks. Some Chicago jobbers ordered coal shipped all along the line, between here and Chicago, for speculative purposes, and when the market broke on the announcement of the strike settlement, they found it very hard to sell, and most of it has reached this end of the line. Their efforts to dispose of this coal has had a tendency to break prices on the steam grades. Soft-coal prices are very weak and price cutting is going on to a great extent.

The Illinois mines are not doing much and it is thought that they will withhold

mining until there is more of a market. The Illinois representatives here seem to have no prices to work on.

The anthracite proposition is almost at a standstill, and the expected new scale of prices did not, of course, arrive, owing to the further disagreement with the miners in that field. There is very little anthracite coal of any size to be had, and consumers will not buy their winter's supply until later in the summer, unless some inducement is made in the way of prices.

Portland, Ore.

The demand has been light for several weeks, owing to the mild weather, and there is every reason to believe that the call for coal now will come only from manufacturing interests. It is expected that storage prices will soon go into effect. There has been no change in prices here since last fall.

Receipts are naturally light here at this time of the year and it will be fall before any shipments will begin to arrive from Australia. Last year the Australian importations were light, but as the demand was light, too, dealers here are pretty well supplied.

Production and Transportation Statistics

Anthracite Shipments

Total shipments of coal in April were 266,625 tons as compared with 5,804,915 in April, 1911, and 6,569,687 in March, 1912. The shipments in April were 5,538,290 tons less than in that month of last year. Practically no coal whatever was mined in April, which accounts for this showing. The shipment by the different companies in April this year and last, were as follows, in long tons:

Company	1912	1911	Dec.
Phila. & Reading...	31,324	1,174,837	1,143,513
Lehigh Valley......	4,840	1,049,164	1,044,324
Cent. R. R. N. J...	58	777,438	177,380
Del. Lack. & West..	112,858	756,019	643,161
Del. & Hudson.....	......	538,026	538,026
Pennsylvania.......	49,687	635,330	585,643
Erie..............	67,798	681,524	613,736
Ont. & Western....	60	192,567	192,507
Total...........	266,625	5,804,915	5,538,290

The Virginian Ry.

Total coal shipments over the Virginian Ry. for the month of March, 1912, amounted to 303,159 tons. No coke was shipped during this period.

The Consolidation Coal Co.

The tonnage of the Consolidation Coal Co. was exceptionally large for the month of April. The total output for the month was 950,000 tons, or an increase of about 300,000 tons as compared with the corresponding month of last year. The Consolidation is now rushing work on its Kentucky railroad, which taps a large coal area in that state, and the line will probably be completed some time in June.

Imports

The total imports of bituminous coal into the United States, for March, 1912, were 120,355 tons, as compared with 148,751 tons in the same month last year. Imports of coke for March of this year were 7418 tons as compared with 14,290 tons for the same month last year. No anthracite was imported during March.

Exports

The exports of anthracite during March of the current year amounted to 277,283 tons as compared with 136,723 tons in March of last year. Bituminous exports for March of this year, exclusive of bunker or fuel coal laden on vessels in the foreign trade, were 973,096 tons as compared with 721,181 tons for the same month last year. Bunker or fuel coal laden on vessels in the foreign trade during March of this year amounted to 671,053 tons, as compartd with 574,409 tons during the same month last year. Coke exports fell off during March of this year to 70,393 tons, as compared with 76,866 tons for the same month last year.

Baltimore & Ohio R.R. Co.

The coal and coke shipments over the lines of the B. & O. R.R. for the month of March, 1912, and for the same month of the previous year, were as follows:

	1911	1912
Coal................	2,027,245	3,173,168
Coke................	371.219	384,094
Total.............	2,398,464	3,557.262

Pennsylvania Railroad

Statement of coal and coke carried on P. R.R. Co.'s line east of Pittsburg and Erie, for the month of March and first three months of 1912, in short tons:

	March	3 Months
Anthracite............	1,140,976	3,288,737
Bituminous............	4,501,653	12,169,935
Coke..................	1,147,602	3,111,786
Total................	6,790,241	18,570,458

Foreign Markets

Toronto, Canada

Owing to the British coal strike, the Nova Scotia mines have greatly increased their output for the first quarter of the current year and extended their export business considerably. Should the production be maintained at the same rate throughout the season, the total output for the year will exceed 7,000,000 tons.

The markets of South America have, for the first time, been available for Nova Scotia coal. The Nova Scotia Steel & Coal Co. has so far shipped about 30,000 tons to Montevideo and Buenos Ayres, and the Dominion Coal Co. has also made some consignments to the same markets, as well as to the West Indies. Much coal has also been sent by the Cape Breton companies to European ports, including one cargo to London. The steamer "Tokomaru," of the Shaw Savill & Albion line, recently sailed from North Sidney with a cargo of coal for Capetown, South Africa, and had sufficient fuel to last her for a trip to New Zealand. Canadian exports for the current year will probably show a good increase.

Financial Notes

Assets of the International Coal & Coke Co. at the close of the year 1911 were: Coal lands, $3,116,118.90; plant buildings, horses, etc., $640,426.43; warehouse stock, $39,256.37; current accounts receivable, $90,616.69; stock of coal and coke on hand, $2582.25; unexpired insurance, $1269.28; timber rights, $4304.82; total, $3,894,563.34.

The Pittsburgh Coal Co. strengthened its financial position during the past year by purchase and cancelation of $8,600,000 first mortgage bonds at 110 and interest. It was enabled to do this as a result of sale of about 7000 acres of measured coal to H. C. Frick Coke Co. for an aggregate consideration of not less than $10,000,000.

The securities and cash set apart in the coal loans sinking fund of the Lehigh Coal & Navigation Co. now amount to $1,031,131. The fund has now reached such proportions that with the accretions due to the investment of its annual income at 4% it will in 40 years equal the value at which the coal lands are carried on the books of the company and under the circumstances the board is of the opinion that appropriations for the fund direct from the income are no longer desirable.

In the foreclosure sale proceedings brought by the Bankers' Trust Co. of New York as trustee under the mortgage securing the $200,000 prior lien 5% bonds which matured July 1, 1911, it is held that the Wheeling & Lake Erie Railroad Co. is obliged to pay off and discharge the sale. The protective committee for the $634,500 first mortgage 4% bonds opposed the suit on the ground that the railroad company, which owned and controlled the coal company, should pay the latter's debt.

Jamison Coal & Coke Co., of Pittsburg, Penn., has issued $5,000,000 first mortgage 5% sinking fund gold bonds dated Apr. 1, 1912, and due May 1, 1931, redeemable at any date at 105 and interest. The company has been in successful operation since 1892, and owns in Greenburg Basin, West Moreland County, Penn., 5350 acres of high-grade steam and coking coal, 1800 acres of surface, six mining plants, 1400 coke ovens, miners' houses, railroad sidings, etc. Property valued at $9,000,000 on which the bond will be a first lien.

The United States Smelting, Refining & Mining Co. has organized the Utah Co. of Maine for the purpose of acquiring a number of large coal properties in Utah. All the stock of the Utah Co. will be held the Smelting Co. and the new properties will be paid for by an issue of notes of the Utah Co. guaranteed by the Smelting Co. and secured by the pledge of large interests in the Castle Valley Coal Co., the Black Hawk Coal Co. and Consolidated Fuel Co., and also by the capital stock of the 80-mile railroad, which is to be built to Spanish Fork in order to give these properties direct connection with the Union Pacific System.

50 H.P. Link-Belt Silent Chain Drive from Motor to Countershaft in Retarding Conveyor
New River & Pocahontas Consolidated Coal Co., Canebrake, W. Va.

Why is the Drive Important?

You are *paying for* all the power you develop. You are *using* only the power you transmit.

The *difference* is *waste*, which should be charged *principally* to transmission or *drive*. That's why the *drive* is *important*.

In the *belt* drive there is *slippage*, and loss from stretched belting.

In the *gear* drive there's *excessive tooth-wear*, shock and strain, which means *loss of power*—and there's noise and clatter.

Neither of these drives can be expected to give *full power*. Therefore your machine cannot reach its *highest efficiency* point with them.

That is why it is *tremendously* important for you to study the use of

Baldwin-Westinghouse Mine Locomotive

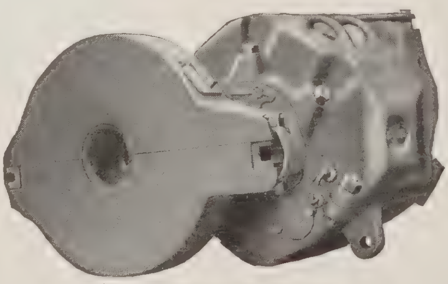
Apparatus that will give thoroughly satisfactory service is produced by long practical experience.

Baldwin-Westinghouse Electric Mine Locomotives

are the products of the combined experience of the Baldwin Locomotive Works, for 80 years the foremost locomotive builders in America, and the Westinghouse Electric & Mfg. Company, the leader in the manufacture of electric haulage equipment ever since the beginning of electric traction.

This experience is embodied in the design of every detail in the construction of Baldwin-Westinghouse mine locomotives. Each part is known to be best adapted to the service it must perform.

In consequence, Baldwin-Westinghouse mine locomotives are, above all, reliable.



Westinghouse Mine Motor

They do their work steadily day in and day out, getting out maximum tonnage at the least expense and in the shortest time.

There is a Baldwin-Westinghouse locomotive for every class of service. The proper locomotive for your mine will be recommended by Westinghouse engineers after a careful study of conditions.

Address either Company—

COAL AGE

Vol. 1 NEW YORK, MAY 25, 1912 No. 33

Some time since an interesting discussion was started among COAL AGE readers by a reference in these columns to a disputed question on the correct method of sealing off a mine fire.

The echoes of that discussion are still heard and give such strong evidence of its practical value to mining men that we are prompted to suggest another question of mining practice concerning which opinions vary.

A while ago an editorial reference in COAL AGE (Jan. 13) instanced a mine superintendent who "erected an exhaust fan at the upcast to assist the blowing fan at the top of the downcast shaft" and later ordered it removed when he found that "the fan last erected would not draw in connection with the fan already forcing the air through the mine."

This statement gave rise to an animated discussion between two mine superintendents in Illinois, one of whom was using the well known "booster" fan, which he claimed, very properly, was performing the work for which it was designed.

The other questioned the efficacy of the "booster" and produced in support of his argument the editorial in COAL AGE, to which we have already referred.

The first man naturally tossed the argument to the winds and declared with much emphasis that he did not care what anyone said to the contrary; "With the 'booster' running, the men could work; but without it, not a man could stay at his place long enough to complete his day's work."

Here were *facts* against *theory*; and, as usual in such cases, the theory was misunderstood and misapplied. Both men were right and both were wrong. Why? Because they each failed to understand and properly apply a plain statement.

The question we submit for discussion by our readers is the following: Is it possible to run a so-called "booster" fan to assist in ventilating mine workings where the circulation produced by another fan, either blowing or exhausting, is deficient?

Without prejudice to the discussion, which we invite, but in order to concentrate the arguments of all who take part, we would suggest that there are two propositions that should be considered:

1. The conditions in the mine may be such that both fans are working on what are practically two distinct circulations.

2. One of the fans may be run at a speed that is capable of generating a greater velocity in the air than that induced by the other fan.

To state these two conditions more clearly:

(a) Suppose a blower fan is forcing 20,000 cu.ft. of air into a mine; but owing to leaky stoppings, brattices and doors, one or more of the innermost sections of the mine are practically without air. The air in the intake of these sections is "dead." A small "booster" is installed at this point and does the work, drawing the air from the other current and passing it through the inner sections.

Again (b), suppose the second fan is erected at the return end or opening, to work as an exhaust fan on the main current, or tandem to the first. Is this arrangement feasible and will it give results? In other words, can two fans be run tandem, the one forcing and the other exhausting on the same direct current?

Let us have a full and free discussion of this practical question.

The Roslyn, Washington, Coal Field

By Joseph Daniels*

This is the first of two articles describing one of the most important of the Pacific Coast coal fields. It discusses the geology and the various methods of development in use, including shafts, slopes and rock tunnels; also a number of difficult and novel rope haulage systems. The second instalment dealing with the methods of mining will appear in an early issue.

*College of Mines, University of Washington, Seattle, Wash.

The Roslyn coal field, of Washington, is situated in the west-central part of the state, in Kittitas County, about 100 miles southeast of Seattle. Its area is about 30 square miles and it lies just east of the Cascade Range in the borderland between the range and the Columbia plain. As a coal field it is isolated and seems to form no part of any other coal district of the state.

The Yakima River, just south of the district, is the most important stream in the drainage system. It is joined by the Cle Elum River at a point a few miles west of the town of Cle Elum. The general course of these streams is southeast. The Northern Pacific and the Chicago, Milwaukee & Puget Sound railroads follow the general course of the Yakima River in crossing this part of the state. Cle Elum is the station for the Roslyn field on the main line of both roads. Only the Northern Pacific taps the district now in operation. This it does by the Roslyn branch line, which runs six miles from Cle Elum to Lakedale, near Cle Elum Lake. Roslyn, in the center of the mining district, gives the field its name.

The field covers the valleys of the Yakima and Cle Elum Rivers, and is bounded by hills on both the north and south sides. The branch railroad, at Cle Elum, has an elevation of 1911 ft., at Roslyn 2222 ft., and continues to rise until it attains an elevation of about 2500 ft., which is at the end of the line. The hills on the north side, back of Cle Elum, have a maximum elevation of about 3300 ft., and those back of Roslyn, 3800 ft. They are composed of the sandstone of the Roslyn formation and rise gradually from the general level of the valley. Ravines along these hills expose the coal along irregular lines of outcrop. On the south side of the main valley, a ridge of basalt, andesite, and metamorphis schist rises abruptly in a pronounced range of hills 2500 ft. above the general level. A number of gravel terraces which occur between the flanks of the hills on both sides of the river cover the coal so that no outcrops are found in the southern part of the field.

Two Views of the Roslyn Fuel Co.'s Beekman Slope, Which Was Driven Out from the Inside

Geology

The rocks of the Roslyn field are made up of sedimentary measures, deposited in a lake or lagoon during the Eocene epoch of the Tertiary period, and of igneous flows which separated periods of gentle uplift occurring between the successive stages of the sedimentation of the Eocene in this area.[1] [2] The sedimentary measures consist of sandstones, shales, and coal beds, having an estimated total thickness in the Roslyn formation of 3500 ft. The Roslyn formation is partly concealed by the Yakima basalt of Miocene age, under which it dips, and it overlies the Teanaway basalt, which also is of the Eocene epoch. The upper portion of the Roslyn only is of economic importance as it alone contains the known and workable coal seams.

The greater part of the Roslyn formation is made up of massive yellow sandstone. The shale beds vary from fine grained to sandy and no subdivision of the beds has been attempted. Several seams of coal have been found, but at the present time only one, the Roslyn, is of great importance. A new mine has recently been opened on an overlying bed, the so called "Big Dirty," and prospecting is being carried on in the underlying seams. Sufficient information is not yet available to correlate these openings.[3] [4]

The strata of the Roslyn formation in this field lie in the general form of a syncline, the axis of which has a pitch to the southeast. The present workings are all on the northeast side of the field; the measures here have a southwest dip which varies from 10 to 30 deg., but which flattens out as the basin of the synclinal is approached. At the east end of the field the workings end abruptly without indicating any structural change; at the west end, as the workings approach the point where the pitching synclinal axis intersects the surface, the

[1]Mount Stuart Folio, No. 106. Geol. Atlas, U. S. Geological Survey, 1904.
[2]Snoqualmie Folio, No. 139. Geol. Atlas, U. S., U. S. Geological Survey, 1906.
[3]Washington Geological Survey, Annual Report 1901, Vol. I, 1902.
[4]Washington Geological Survey, Annual Report 1902, Vol. II, 1903.

levels swing around at an angle of over 90 deg. This seems to indicate that the Roslyn bed has an extreme length of about 7½ miles in a northwest and southeast direction.

The Coal

The most important seam, the Roslyn, is a hard and compact bituminous steam coal. The thickness varies with the locality from 4 ft. to 4 ft. 9 in., with a general average of 4 ft. 3 in. The coal thins down to 2 ft. or less in the "troubled" or "faulted" areas, while in other places it will increase to twice or three times the normal thickness, but the average may be taken at 4 ft. 3 inches.

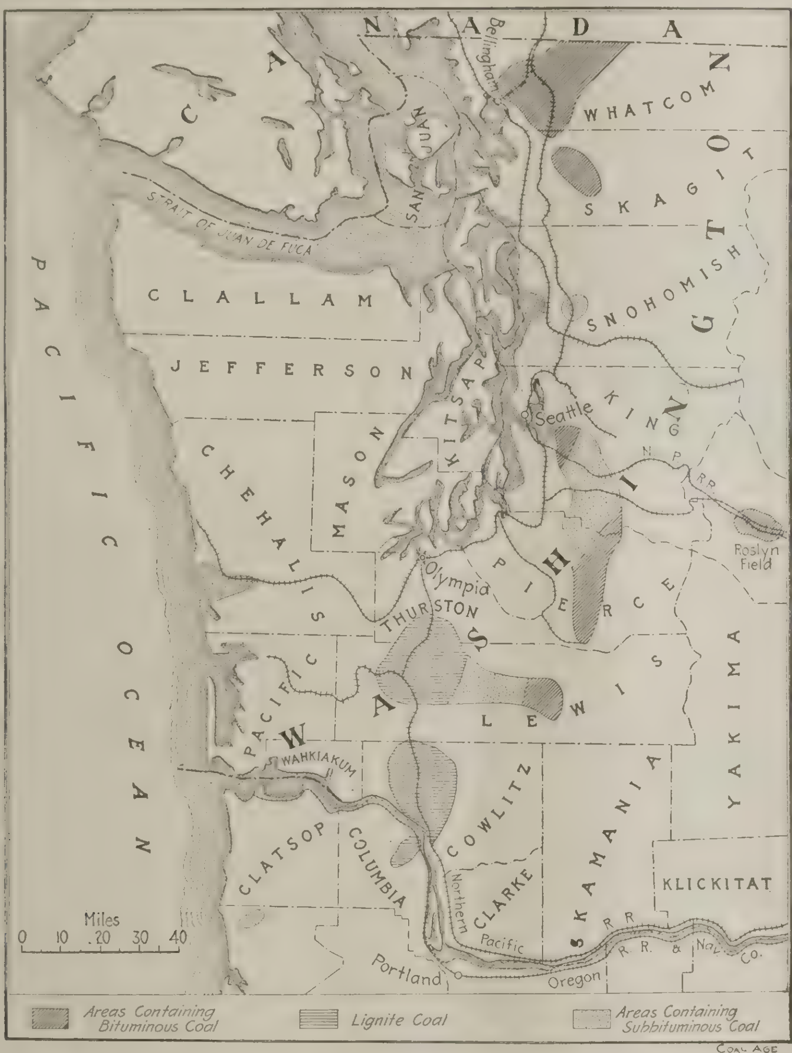
The following may be taken as an average section of the coal:

Roof, sandstone.
Cap rock, shale (variable thickness).

	Inches
Coal	29
Shale	1
Coal	4
Shale	½
Coal	20
Total	4 ft. 6½ in.

Bottom, firm, sandy shale.

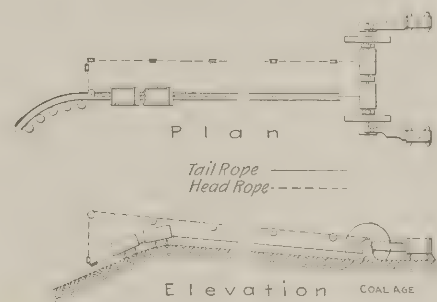
The coal changes in character from one part of the field to the other. At the southeastern, or Cle Elum end, the coal is banded and laminated, resembling bony; at the northwestern end it is denser and breaks with a cubical fracture. The ash in the coal from Cle Elum is greater, the heating value lower and the coking quality less marked than in the coal from the other end of the field. Some of these differences may be explained by the change in the structure of the coal basin as it approaches the western uptilt of the synclinal axis. This change was caused by the increased dynamic action which occurred toward the hills of the Cascade Range.



Map Showing Coal Fields of Western Washington

Moisture in this coal is low. The ash is higher than it would be if the thin shale, clay bands and partings were removed either in mining or in subsequent preparation. The amount of sulphur is small. The accompanying representative analyses taken from a series of 60 samples obtained at Cle Elum, Roslyn, and Beekman, the western end of the field, will give a good idea of the composition.[5]

The domestic market for Roslyn coal is mainly in the eastern part of the state of Washington. Transportation rates over the steep grades of the Cascades to the Puget Sound markets are high, and furthermore, the coal is in competition with the mines of the western part of the state. At the present time, the greater part of the output, about 85 per cent., is used for steaming purposes by the railroads. The marketed coal is used in gas making and for domestic purposes; none is used directly for coke making.



Haulage System at the Dip Mine

Production Statistics

The greater part of the coal lands represented by the Roslyn field are owned and operated by the Northwestern Improvement Co., a corporation affiliated with the Northern Pacific R.R. Part of these lands include the original grant of each odd section for 20 miles on each side of the right-of-way of the road; the rest have been secured by purchase. Three or four independent companies operate small mines. The field was first opened up in 1886 and in December of that year, coal was dumped over the tipple of No. 2 mine. Production, therefore, may be said to have begun in 1887, and during

[5] "Coals of the State of Washington," Bulletin 474, U. S. Geological Survey, 1911.

*Analyses made on air-dried sample. **Calculated from air-dried sample.

the three years, 1887 to 1889 inclusive, 230,548 short tons were produced in Kittitas County. In 1891 the production amounted to 331,444 tons; in 1900, 867,-204, and in 1910, 1,667,453 tons were produced, which is the banner production for the county.[6] The production for the calendar year of 1911 was 1,254,845 tons, a slight decrease over 1910.

The entire production of the state of Washington in the years 1860-1910, according to the figures of the U. S. Geological Survey,[7] was 53,647,802 short tons. In the period 1887-1910, the production was 51,084,344 short tons. In the latter span of years, the Roslyn field furnished 18,229,610 tons of this output—very nearly 30 per cent. of the whole.

An estimate, recently made by the State of Washington Geological Survey places the original coal content of the Roslyn bed at 71,877,840 tons, covering an area of 9661 acres. Of this content, 65,353,600 tons are estimated as "known workable" and 16,-524,240 as "probable" coal. The percentage of recovery in the old workings was taken as 70 per cent. and, from calculations made on this basis, it is believed that the future recoverable coal in the Roslyn bed is 34,054,691 tons.

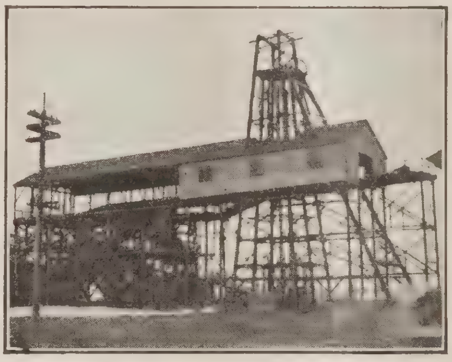
Different Methods of Working

The surface topography of the Roslyn field and the position of the coal with relation to the main surface features have been responsible for considerable variation in the methods of opening and working. The outcrop of the Roslyn bed is found on the north side of the valley, along the hills, at an elevation varying from 2000 ft. at Cle Elum to a maximum of 3700 ft. back of Roslyn. From that point it follows the irregular line of the general topography which roughly resembles a bow and reaches the Beekman mine where the elevation of the bed is 2200 ft. The coal is also exposed in the ravines which cut the hills at frequent intervals.

The general slope of the surface corresponds with the angle of dip of the coal, so that the seams dip to the southwest and yet have a fairly uniform cover of from 100 to 200 ft., up to the point represented by the toe of the hills, where the depth of cover begins to increase rapidly and finally reaches a maximum of about 1000 ft. in the synclinal basin. Since no outcrops occur on the south flank, the only data in regard to the seams must be obtained from bore-holes. The coal can be opened by drifts from the ravines, by slopes from the outcrops, by rock tunnels to the coal at points below the outcrop, and by vertical shafts and slopes. All of these methods are in use.

Two shafts, the Cle Elum No. 1, 250 ft. deep, at one end of the field, and the Roslyn No. 4, 625 ft. deep, near the center of the field, have been sunk to the coal, each reaching the seam at approximately the same elevation. From the shaft bottoms, slopes have been driven in the coal. Numerous air shafts have been sunk throughout the field but in no case are they used for other than ventilating purposes. Of the true slope mines, that is, slopes which hoist coal to the outcrop, only two in the whole field, Beekman No. 1 on the Roslyn Bed

View of the Cle Elum Mines



The No. 4 Shaft, at Roslyn

and Beekman No. 2 on the Big Dirty, will be noted. Slope mines which are tapped by rock tunnels are more frequent. Among these are Roslyn Nos. 3, 5 and 7, and the Patrick-McKay Nos. 1 and 2. In a number of these, the slopes have been extended to the outcrop. The drift mines are mainly the "hill workings" along the ravines. Cle Elum No. 2, No. 3 Extension, Roslyn No. 6, No. 2 East Side, and some small operations represent this type. The other mines, Cle Elum No. 2, Roslyn No. 1 and No. 2 Dip, are worked by slopes connected with drift openings.

Haulage System

The whole problem of surface and underground transportation is so intimately connected with the topography and method of opening the beds that it should be considered at this point, previous to the discussion of the methods of working. From the main openings to the seam, levels are driven in the coal at intervals of 350 to 400 ft. and usually on an ascending grade of 1 per cent. in favor of the loads. In the case of drift openings, the same method is followed. Landings or gathering stations are provided at the entrance of each level, and trips are made up or distributed from this point either by mule or electric power. General Electric, Westinghouse and Jeffrey motors operating on 500 volts, direct current, are usually employed.

In the slope and shaft mines, rope haulage, operated by steam or electricity, is the general method of handling the trips. In the slope mines, opened by a tunnel to the coal, the hoisting engine is located in some cases at the top of the slope above the tunnel on the surface, and drops the cars directly to the rock tunnel where they are picked up by an electric locomotive and taken to the tipple. In another arrangement, the hoisting engine is below the intersection of tunnel and slope and the rope is taken from the drum to a bull wheel inside the mine and from there down the slope. In this case, the trip is dropped right down to the tipple by the drum. The bull wheel may be so placed that this arrangement will permit full cars to be taken up the slope or dropped down from the "hill" or rise workings above the tunnel.

At the Dip Mine the trip is taken into a drift, as a rope entry, on a rising grade, then dropped down the slope. The empty trip is taken in on a head rope passing over sheaves and a bull wheel to the knuckle, and carries a tail rope connected with the second drum of the hoisting engine. At the knuckle, the head rope is disconnected, and the trip dropped down the slope by the tail rope. The accompanying sketch illustrates the method.

Another arrangement was used at the Roslyn shaft. The rope was carried from the surface down a 10-in. bore-hole, 500 ft. deep, and the trips pulled up the haulage slope to a point above the shaft bottom and then dropped back to the shaft and hoisted on double-decked cages. Finally, the simplest method of all includes engine haulage on the main slope to the outcrop, and the dropping the cars from the knuckle down to the tipple. In the drift mines the full cars are dropped to the tipple below and the empties raised by gravity or engine planes. Some of these planes are considerably over a mile in length. In every case, the tipple is below the mine opening.

The usual weight of rail on the levels is 16 lb., and on the slopes, 30 to 40 lb. The gage of track is 30 or 36 in., and the weight and capacity of mine cars vary. An average weight of an empty car is 1500 lb. and its capacity 2500 lb.; from 10 to 16 cars make up a trip.

The New Buck Mountain Colliery

By E. L. Cole

Following the article in Coal Age of May 18, which dealt with the Buck Mountain breaker, details of the belt-loading and car-handling systems are here considered. The boiler, engine, and miscellaneous equipment of the colliery described.

In the article describing the Lehigh Valley Coal Co.'s new Buck Mountain breaker, which appeared in the preceding issue of Coal Age, it was stated that the methods of loading and handling transportation cars were features of particular novelty and interest. As previously explained, coal of all sizes is carried from the storage pockets and loaded into cars by means of a belt conveyor, with adjustable boom end. This conveyor installation consists of a 36-in. Webster rubber belt, running on Robins troughing and return idlers. It is driven at a speed of 200 ft. per min. by a Lycoming high-speed engine, through belt and gear transmission.

One Man Does the Loading

A layout of the loading arrangement is shown in the sketch, Fig. 1, the entire operation being controlled by one man. The belt is started or stopped by means of a hand lever and a friction clutch on the engine drive. A steam cylinder and piston raises and lowers the boom end of the conveyor as desired. This mechanism is controlled by a four-way valve, conveniently located in front of the operator. A similar steam cylinder with controlling valve opens and closes the pocket gates, by means of seven distinct sets of connecting levers and shafts, which run to the different storage bins and are thrown in and out of connection with the operating mechanism by means of jaw clutches and suitable hand levers. The gates of any particular set of pockets may be operated by simply throwing into mesh the corresponding clutch and admitting steam to the cylinder.

Coal is discharged from the end of the belt into an adjustable chute, which leads it to the cars. Removable screen plates are provided in the bottom of this chute, in order to remove any fine coal which may have resulted from breakage in the pockets. This fine material, together with a certain amount of dirt, which adheres to the belt and tends to travel back with it on the return run, is collected in a hopper beneath the loading head and carried away by a small scraper line, which returns it to the breaker.

Automatic Belt-loading Device

An interesting detail of the installation is the use of small counter-balanced lips on the ends of the chutes, which carry coal to the belt. A sectional view of one of these lip chutes is shown in the sketch, Fig. 2. It is automatic in its operation, inasmuch as the weight of the descending coal causes it to drop into the position shown in the figure; but as soon as the flow of coal has ceased, it is drawn up out of the way by the counterweight. These lips are installed to secure an even loading of the belt, a matter which is essential to its satisfactory operation. Since the conveyor is loaded at a number of different points along its length, a stationary construction extending down close to the face of the belt would not be permissible.

Handling Cars by Cable Haulage

Handling cars to and from the breaker by other means than gravity is a decided innovation in the anthracite field. At Buck Mountain, as stated in a previous article, a continuous cable haulage is employed. The endless rope of this system runs up and down between the tracks of both empty and loaded yards, being so arranged with respect to any particular line of track that the rope travels up one side and down on the other. The rope is carried on gum-wood rollers, and guided, where necessary, by cast-iron side sheaves, complete changes of direction being made around sheaves of large diameter. At the end of its run, the cable passes beneath the tracks and returns on the opposite side. The rope is driven by a Litchfield haulage engine of the type shown in Fig. 5. This is located near the breaker at approximately the center of the system. A heavy counterweight, which operates in a tower just outside of the haulage-engine house, is provided, to insure the necessary tension of the rope.

Cars are attached to the rope by means of a Morgan cable grip and a length of chain, which is hooked by the attendant to some convenient part of the car. The

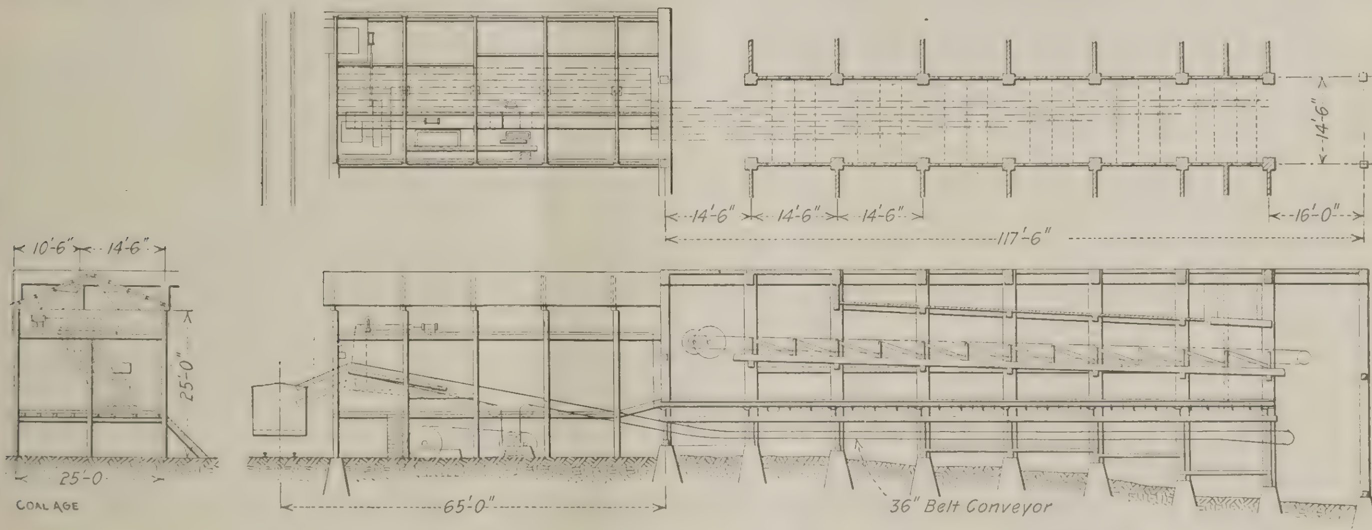

Fig. 1. Arrangement of Storage Pockets and Belt Conveyor for Loading Cars

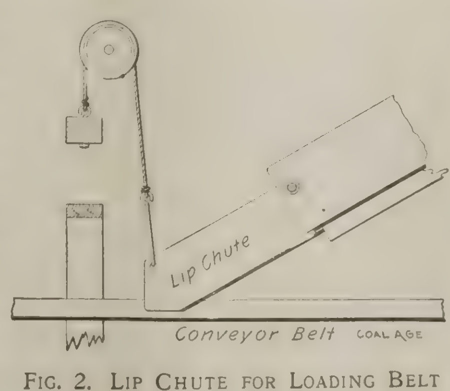

Fig. 2. Lip Chute for Loading Belt

grip, as shown in Fig. 6, is controlled by a hand lever, and it will be noted that to release its hold on the rope it is only necessary for the operator to halt, thus throwing the lever back by retaining his hold on it.

Boiler-plant Equipment

The boiler house at Buck Mountain is located about 100 ft. to the north and west of the breaker. It is a concrete building with steel roof trusses and corrugated iron roofing. One end is closed with a wooden frame and sheathing, to facilitate an extension of the plant when required by future developments. A monitor, extending nearly the full length of the building, is equipped with two lines of pivoted window sash, providing ventilation and some additional light.

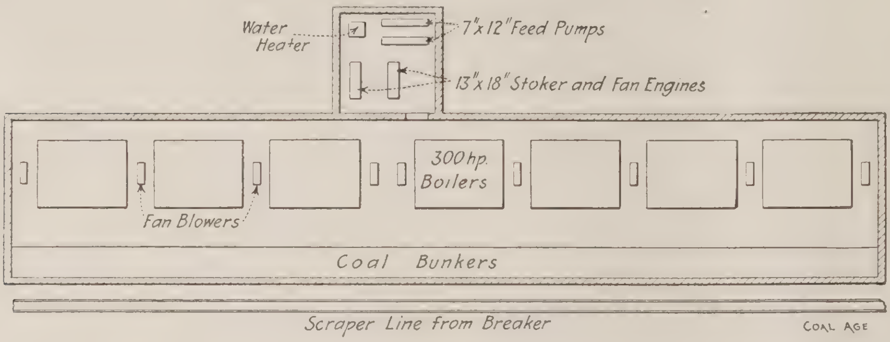

Fig. 3. Sketch Plan Showing Layout of Boiler House

This building houses an installation of seven 300-hp. batteries of Sterling boilers, making a total rated capacity of 21,000 hp. The boilers are equipped with Coxe traveling grates and Sturtevant forced-draft fans. The general plan of the plant is indicated in the sketch, Fig. 5, and a sectional elevation is shown in 3, and a sectional elevation is shown in Fig. 4.
the breaker, by a scraper line, which is driven by an 11x16-in. Atlas engine. This conveyor dsicharges into bunkers within the boiler room, or may be used to accumulate a reserve storage pile just outside of the building. From the overhead bunkers the coal is fed automatically to the Coxe grates. These are driven by belt connection to a line-shaft running the full length of the building, in front of the boilers. Four-cone pulleys are provided for regulating the speed of the grates in accordance with the demand for steam. The whole system is driven by belt connection to a 13x18-in. Atlas engine, located in the pump room, near the center of the building.

Forced-draft Fans for Each Setting

Forced draft for the boilers is provided by No. 7 Sturtevant fans, which are located in the alleyways between the settings, each fan supplying two boilers. These blowers are supported on steel beams at a height of 8 ft. above the floor level, and are driven by belt connection to a line shaft running the full length of the building behind the boilers. This arrangement provides considerable flexibility in the matter of air supply and leaves the passageways between boilers unobstructed. The fan line shafting is driven by a 13x18 Atlas engine in the pump room, this being a duplicate of the engine which operates the traveling grates.

Steam is taken from the boilers by the usual U-bends, to a header line, which runs overhead above the alleyway at the rear of the settings. The boiler-room steam lines are all of steel pipe with recessed-lap-joint flanges. This plant was installed to supersede the separate equipments located at the old Buck Mountain and Vulcan collieries, as well as to supply the needs of the local surface operations. Both of the above mentioned plants have now been dismantled and steam is supplied to these two operations by 8-in. lines, proceeding east and west from the new installation.

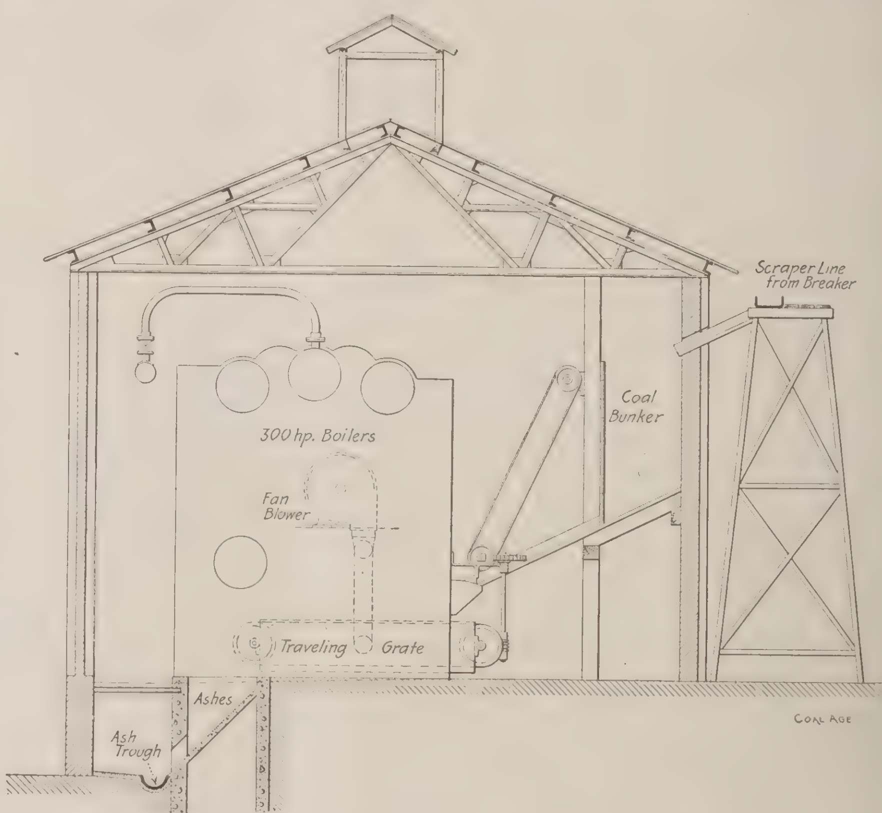

Fig. 4. Sectional Elevation of Boiler House

Ashes Removed by Flushing

The Coxe grates discharge into concrete ash pits, formed below the floor level at the rear of the boiler foundations. From these hoppers the ashes run to a line of half-round terracotta trough in the ashway at the rear of the building, and are washed out by water from the screens and jigs in the breaker. This water first enters a storage tank at the west end of the boiler house and is drawn from there as required.

Feed water is obtained from three wells, 750 ft. deep, one being of 3-in. and two of 4-in. diameter bore. These have a capacity of approximately 500 gal. per min. The water is forced by compressed air into a group of Caldwell tanks at the top of the bore holes, and flows thence by gravity to two 25,000 gal. steel storage tanks located near the breaker. The boilers are supplied by means of two 7x12 in. Scranton feed pumps, which draw their supply through a Cochrane feed-water heater. This latter raises the temperature of the feed water up to 210 deg. F. and is supplied with exhaust steam from the adjacent breaker engines and boiler house auxiliaries.

The plant is operated by three shifts of four men each, and one foreman, who is on duty during the day and acts in the capacity of machinist and repairman.

A Model Engine House

The breaker engine house is located directly to the rear of the breaker and is separated from that structure by a space

of 37 ft. It is a building 70 ft. long, 40 ft. wide and 18 ft. high, of concrete construction, with steel roof trusses and purins and corrugated iron roofing. The metal roofing is lined on the under side with asbestos sheeting, held in place by wire netting. This is done to prevent the sweating action of an unprotected metal roof. The building, as a whole, represents a radical departure and great improvement in the design of engine houses in this field. There is provided throughout not only ample working space but an abundance of light and adequate ventilation. All piping is carried beneath the floor, in concrete ducts or runways. These are covered in some cases by removable floor slabs of concrete, and in other instances by cast-iron plates, depending on the frequency with which the underlying pipes will probably require attention.

An equipment of four engines is housed in this building. These all operate at 150 lb. steam pressure. An 18 and 26 x 30-in. tandem-compound Vulcan Iron Works Corliss engine, running at 100 r.p.m., drives the greater part of the breaker machinery through a 24-in. belt drive to a line shaft located in the upper and rear part of the structure. This belt, in its passage from the engine house to the breaker, is protected by a housing of corrugated iron on a specially designed steel frame work.

The jigs are driven by a 12 and 16 x 24-in. tandem compound Corliss engine running at 125 r.p.m., and power is transmitted to the jig-line shafts by 1½-in. manila rope drives. A 16x30-in. simple engine drives the Gates crusher and refuse conveyor line, and mine cars are lifted from the ground to the head of the breaker by a pair of 16x30-in. second motion hoisting engines. The self-dumping cages operating in this tower hoist are remarkable for the simplicity and strength of their construction.

Locomotive House and Carpenter Shop

In addition to the portions of the colliery which have already been considered, the locomotive and compressor house, blacksmith and carpenter shop, and the fan installation are particularly worthy of further note. In the first mentioned building are installed three compressors: one Chicago Pneumatic, one Ingersoll-Rand and one Norwalk Iron Works three-stage machine. The last named furnishes power for two Porter locomotives, which are used for haulage in the mines. The front portion of this same building is fitted up for the accommodation of the two steam locomotives which are used for hauling mine cars on the surface, and the construction of the repair pits for these engines is a feature of particular interest. The tracks are supported on pillars, and the entire space within the limits of the foundation walls is left open, so that mechanics, when working on repairs, are not confined by a narrow pit, and are afforded plenty of daylight to aid them in their work.

The carpenter and blacksmith shop is thoroughly equipped for handling all necessary repair work at the colliery. As to form of construction, it is uniform with the other colliery buildings. The smith shop is located in one corner of the structure, and is separated from the wood-working and machine tools by a substantial partition of tile and cement. A track for mine cars and a repair pit run longitudinally through the building. A drill press, pipe-threading machine, bolt cutter, lathe and circle saw are installed, and all are driven by a 12x16 Atlas engine.

A 20-ft. diameter Guibal-type fan is installed at Buck Mountain, and is driven by a 20x36-in. Vulcan engine. In the fan house also, is located a 12½-kw. Ridgeway 110-volt generator for furnishing light to the colliery operations. This is driven at 900 r.p.m. from the fan-engine shaft by means of a Link-Belt chain. The colliery grounds are lighted by 250-volt tungsten lamps, mounted on 30-ft. poles.

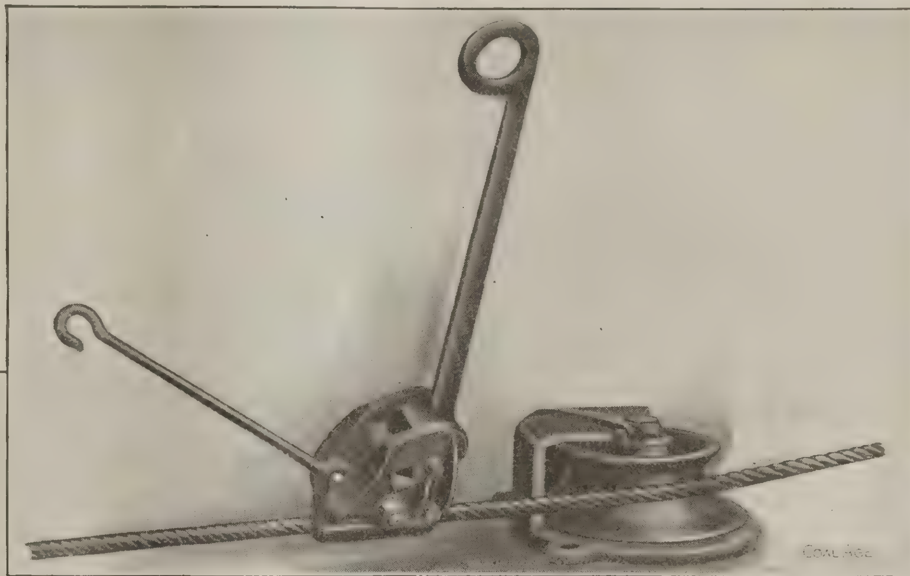

Fig. 6. Grip for Attaching Cars to Cable

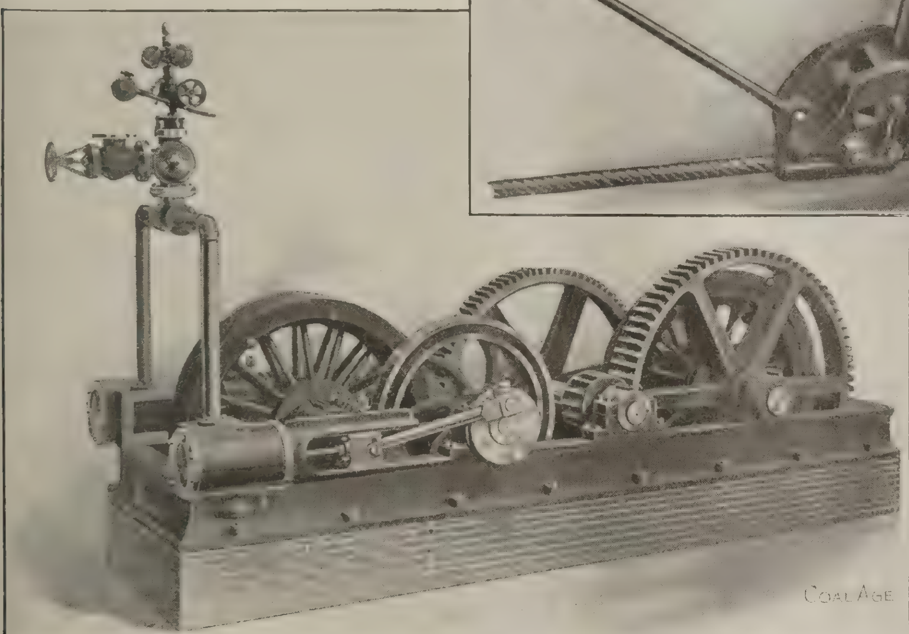

Fig. 5. Endless-rope Haulage Engine for Car-handling System

Time-saving Arrangement of Buildings

All the various buildings, foreman's and shipper's office, storeroom, oil house, shop, etc., are closely and carefully grouped around the breaker, in order to minimize the loss of time by employees in passing from one to the other of these buildings, and the foreman's office is so situated that he may command a view of practically the entire operation.

According to E. W. Parker, because of invention of grates and furnaces adapted to the use of small sizes of anthracite coal (and also because of the higher prices of the prepared sizes), the percentage of waste in anthracite coal has been reduced to a minimum. Buckwheat, rice, barley and even culm are now important steam fuels, particularly in hotels, apartment houses and large office buildings in the cities of the East, where smoke ordinances are in force.

Colliery Boiler Room Practice

By F. R. Wadleigh*

The average colliery boiler room is usually the most neglected part of the surface equipment, and there are often heavy and unnecessary losses in fuel consumption. Some of the more common mistakes and the resulting losses are noted here, together with remedies for the same, and a number of valuable suggestions on boiler room practice in general.

This article refers more especially to the average coal-mine plant. There are many large operations, having central power plants for several mines, equipped with all modern appliances and obtaining results equal to those yielded at any large power plant or station, and a discussion of these will not be attempted.

An experience of some years around coal mines has convinced me that the poorest equipped, worst handled, and least cared for place about the average 200- to 1000-ton capacity mine is the boiler plant. This seems rather strange when it is remembered that the entire working of the mine is absolutely dependent upon the work done by the boilers; yet the reasons for the neglect of economical methods of using coal are not far to seek—lack of knowledge, lack of incentive and the cheapness of fuel. At no other class of power plants will there be found such abuse of coal, such poor firing and such badly kept up plants.

The General Lack of Knowledge

Efforts on the part of the management to use uptodate and economical methods and appliances are rare. Daily, weekly, or monthly inspections are almost always concerned with the mine, the tipple, and the labor; possibly the engine room is looked into, but the boiler room seldom if ever, or if visited at all, not enough time is spent in it to get any true idea of the working conditions there. Such being the case, it is not surprising that the average mine superintendent pays so little attention to the condition of his steam plant, or to economical methods of operation, and there is little incentive to study combustion questions and the economical handling of the power plant.

There is a lamentable lack of knowledge among mine superintendents and mine bosses as to the proper methods of firing and the conditions under which coal should be used. It is true that nearly all of the mine-foremen examination papers contain questions on combustion and boilers, but these are more or less perfunctory and may easily be learned for the time being, their practical use and importance not being sufficiently emphasized. As long as sufficient steam is kept up to run the plant and no breakdown occurs, the boiler room is let alone to run itself and as little money as possible is spent on it.

That these methods are conducive of much loss will hardly be disputed. In the boiler room, the load, draft, coal, the condition of the fires and boilers, in fact, almost every item, is of a variable nature and lack of knowledge or stupidity will surely lead to excessive consumption of coal and, at some time, a heavy expenditure for repairs or damages.

The mine superintendent should familiarize himself with the principles of combustion, the results that can be obtained with the coal he is mining and the proper use of everything connected with the boiler plant, together with the conditions which will give the best results in economy of fuel and efficiency of working; he should have the requisite knowledge to formulate and put in force proper instructions for firing, cleaning boilers, and the general operation of the steam plant.

Some Typical Colliery Boilers

Cheapness of fuel is probably the principal reason why more attention is not paid to the boiler room and its equipment and operation. But, obviously, the simple fact that coal is cheap is no valid excuse for lack of efficiency in the power plant and saving in the amount of coal used means increased output for commercial purposes, lower mining cost, less depreciation and lower cost of repairs. In fact, the actual cost of the coal used should be made lower by burning the lowest grade made or by using the bone or refuse thrown out at the tipple, either of which may be made available by proper instruction and the use of suitable appliances.

As concrete examples of bad conditions actually observed at different mine power plants, the following will be of some interest:

Due to change of ownership an examination was made of the four water-tube boilers at a certain mine and over 200 tubes had to be removed, most of them badly burnt and all of them stopped up more or less. As a result, the coal consumption was cut down, after new flues had been put in, over 25 per cent.

Lack of steam to run the tipple caused an examination of the furnaces and fires and it was found that the fires had not been thoroughly cleaned for a long time, the back half of the grates being entirely cut off by a solid mass of clinkers 6 in. thick. The bridge-wall was covered with ashes and clinkers to within 2 in. of the tubes and all the brick baffles gone.

Fires 20 to 24 in. thick, the fireman slicing the fire about every half hour and putting on 18 to 20 shovelsful of coal at each firing.

On three boilers used, steam gage showed 120 to 125 lb. pressure on two, while on the third the gage showed 200 lb. where it remained until boiler was allowed to cool down and fires were drawn. No one around the plant could remember when the gages had been tested.

Dampers rusted open and could not be closed, gage cocks would not open, boiler fronts showed cracks ¼ in. wide, ashpits full of ashes to within 6 in. of grates. Boiler settings were also badly cracked.

The above are a few instances of conditions actually seen at colliery plants in this country. Instead of such conditions obtaining, and they are not at all unusual, the boiler room should be a show place where visitors could see for themselves what good results can be secured from the coal and how it should be handled. As a means of enabling the mine superintendent to have such conditions in the boiler rooms under his charge, the following notes and suggestions are given.

Boiler Equipment

Good results can be obtained from any kind of boiler, but the old idea that any kind would do for colliery work is fast disappearing. It is becoming recognized that the best is not too good and that it is economy to have only the best, just as much as at any stationary power plant. Whatever type of boiler may be used, ample heating surface should be provided, so that the inferior product of the mine can be used, if it is thought advisable to do so.

At large mines or where there is a central plant supplying power to a number of mines, it is undoubtedly a good policy to put in automatic stokers, as has been done at a number of large collieries in this country. At the average mine, however, the use of stokers is hardly advisable. There would be no saving in labor and almost as good results may be obtained by the use of shaking grates, close inspection, good firing, and by keeping the boilers, furnace walls, arches and baffles in good condition.

The use of shaking grates is strongly recommended, as with them it may be

*Fuel engineer and assistant general manager, the Chesapeake & Ohio Coal & Coke Co., Norfolk, Va.

possible to burn the refuse or rejected coal from the mines. They will also give better results, if properly handled, with either slack or run-of-mine coal, than will stationary grates, besides making the work of the fireman easier, and giving a better supply and distribution of air to the fires, eliminating much of the trouble of cleaning fires and consequent loss of heat. Whatever kind of grates is in use, attention must be given to the following, neglect of which will nullify the work of the best grates:

Stationary Grates—Keep the air spaces open, and have the grates fit properly; be careful, in using the slice-bar, not to damage the grates, and do not allow badly warped bars to remain in the furnace and waste fuel.

Shaking Grates—After shaking, always be sure that grates are moved back into level position; otherwise they may be partly burned or broken and will waste fuel. As to frequency of shaking, that will depend on the kind of coal used, but do not allow too long a time to elapse between shakings; otherwise clinkers may accumulate and nullify the good effect of the grates. The object of these is to keep the fire clean of excessive ash and not to allow clinkers to form in large pieces.

The Fireman

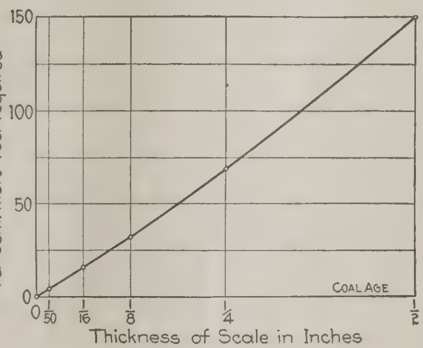
The fireman is the most important part of the boiler plant. It is said by reliable authorities that: "Economy of boiler management is dependent on the skillful handling of the fuel. The fireman can save more to the plant than anyone else," and "To handle a boiler and furnace properly requires expert knowledge and considerable experience and ability. The fireman is, in many respects, the most important man about the plant."

The four main factors affecting fuel consumption are the fuel, air, furnace design and the fireman, and the latter is undoubtedly the most important. Without skill and intelligence on his part no good results may be expected from any grade of fuel or with the best designed boilers and furnaces, as his carelessness or ignorance may nullify such expectations. It should not be a difficult matter for the colliery superintendent to find two or three men of the necessary intelligence and strength whom he can train to take an interest in the work. Especially is this true if he gives some incentive, such as having a decent clean plant to work in and suitable equipment, properly kept up.

Experience has shown that it is much better to use a green man, familiar with the coal and the mine and to train him up properly. Better results will be obtained in this way than by picking up some fireman out of a job whose experience quite often is shown only in his ability to shovel in coal and keep the pump running. Too much stress cannot be laid upon the importance of selecting good firemen, as upon their work depends, in a measure, the whole working of the mine. It will not be necessary to pay more than the prevailing rate of wages if sufficient attention is given to the issuing and carrying out of instructions and to stopping leaks of all kinds and keeping the plant in good repair and equipped with the necessary and right facilities for working.

The Fuel

The question as to what fuel is the most economical for use at the mines should be given careful consideration, but, as a rule, the coal to be used should be that which is the cheapest, providing it will keep up steam. This can only be determined by actual experiment at the particular plant in question, as a fuel that may be entirely suitable at one mine, will not be the best at another.



Fuel Loss Due to Scale

Bone and other impurities thrown out at the tipple often have considerable fuel value, and with sufficient grate surface, and suitable grates, may be used to advantage, provided the cost of conveying it to the boiler room is not prohibitive. Where the impurities consist principally of bone or bony coal, it will usually pay to use the refuse, but where there is a large amount of slate, fire clay or pyrites, its use is not practicable. When it can be arranged, a conveyor line may be run from the picking table, or from a point alongside of the railroad cars, and all refuse, except slate and pyrites balls, thrown into this and taken to the boiler room. Or the refuse may be crushed first and then conveyed to the boiler room. The use of such refuse may often be made possible by putting a steam-jet system under the grates.

Coke Braise, which usually amounts to 1½ to 2% of the coke made, can be used very successfully under boilers with forced draft and suitable grates. In England and Germany it is quite largely used at power plants other than those at the mines.

Slack is probably the best all-around fuel for use under boilers at mines, either by itself or mixed with the bone or refuse obtained from the tipple. It has been found a good plan to screen out the fine slack and dust at the tipple, say everything that will go through a ½-in. screen and convey this to the boiler room. This method will improve the run-of-mine coal, especially where the coal is soft and friable and the screenings will give good results under the boilers.

Run-of-mine, one of the principal merchantable products of the mine, should not be used under the boilers when it is possible to avoid it. If local conditions make it necessary, then such conditions should be changed. There is no sense in using coal that can be sold for $1.10 per ton when coal that brings 75c. can be used equally as well.

The colliery boiler plant is an excellent place to test coal from time to time (as when new seams or new territory is being developed), to ascertain if there is any change in quality of the coal. These need not be elaborate evaporative tests, although such would be better, but merely burning tests, weighing the coal and refuse, and separating the clinkers and ashes to determine whether the coal is clinkering more or less than usual.

Firing

The following suggestions on the best method of firing will be found helpful and embody the best practice in hand-firing at the ordinary stationary boiler plant:

1. Fire evenly and regularly, putting on approximately the same amount of coal each time and with the same interval between firings.

2. Keep fires in such condition that a moderate amount of coal (two to five shovels full) will be sufficient at each firing, and place the coal where needed, only.

3. Keep the fire clean and bright all over, except when using the coking method, where the fresh charge is banked at the door and the fire kept bright back of the bank.

4. Break up large lumps to the size of a man's fist and have the coal as uniform in size as possible.

5. Regulate the draft and air supply to suit the working conditions.

6. Keep the fire free from holes, especially along the sides and back of the furnace.

7. Watch closely the condition of the fire and the steam pressure as they are dependent on each other. If the pressure varies, some change in the fire caused the variation.

8. Keep the steam pressure even and without variation.

9. Carry water in the boiler at a uniform and regular height.

10. Do not level or stir the fire unless absolutely necessary.

11. Find the thickness of fire necessary to prevent smoke and keep up steam and do not allow this to vary.

12. Keep flues and heating surfaces clean.

13. Do not allow leakage of air into the furnace or combustion chamber.

14. Do not allow ashes or clinkers to accumulate on the walls or in the combustion chamber.

15. Clean fires when necessary, but do not allow them to run too long; deficiency of air through the grates means incomplete combustion, loss of efficiency and increased smoke.

16. If the furnace has more than one door or there is more than one furnace to be handled, fire in alternate doors and it is better to put coal on alternate parts of the fire reached by each door. This is the so called "ribbon" method of firing, the coal being put on in alternate strips across the full length of the grate, as shown in the accompanying sketch, *A*, *B*, *C*, and *D* representing that portion of the grates served by one door and 1, 2 and 3, the firing strips across the grates. Firing should be done across *A*1, *A*3; *B*2; *C*1, *C*3; *D*2; then back *D*1, *D*3; *C*2; *B*1, *B*3; *A*2.

This method gives more even temperatures in the furnace, affords a better chance of mixing the gases from the fresh coal with the incandescent gases and heated air from the bright fire, thus preventing smoke, and giving a more even steam pressure, systematic stoking and less contraction and expansion of the boiler plates and flues.

Boiler Records and Inspection

To systematize the work in the power plant and to enable the superintendent to keep track daily of what is being done, records should be kept of the day's work, which should include:

Amount of coal used, estimated or weighed.

Average steam pressure. Every plant of any size should be equipped with a recording steam gage.

Amount of ashes and clinkers removed. These should either be weighed or records kept of the number of loads, as this gives a valuable check on the quality of the coal.

Temperature of the feed water. Hourly observations.

Condition of boilers.

Condition of grates.

Date of boiler cleaning.

Time flues were blown.

Condition of boiler pumps.

The fact that records are kept and followed up is of itself an incentive to the engineer, fireman, and master mechanic to improve their work. It has often been found, too, that an investigation into the cause of poor records has led to either the discovery of a leak, need of important repairs or a revision in methods, none of which might have been discovered without the use of such daily records.

In addition to having daily records, the mine superintendent should, as a matter of course, make a daily inspection of the boiler room, not only to satisfy himself as to the condition of the plant and its handling, but also to show the firemen that interest is being taken in their work and its importance recognized.

Every uptodate colliery boiler-plant should have at least the following equipment:

Feed water heaters. Their value is obvious.

Pumps. Boiler pumps should always be in duplicate or injectors furnished.

Feed water regulators. These save their value in fuel economy, safety, pump repairs and the fireman's time.

Damper regulators. These are important fuel savers and regulate the air supply according to the demand for steam.

Water Supply

The water supply should be closely investigated, as upon this point depends the proper and economical operation of the whole plant. The different sources of supply should be located and a careful comparison of the cost from each source made up. An analysis should then be made of the different waters to determine their value for boiler use, and whether they are corrosive or likely to deposit scale or sediment.

If the latter is liable to occur, steps should be taken to determine how to best neutralize these deposits, and whether it would be advisable to install a water softening plant or resort simply to boiler cleaning compounds. No boiler compound should be used except that specially made for or adapted to the particular impurities in the water under consideration. A compound that will suffice for one kind of water may quite possibly be of no use whatever for another.

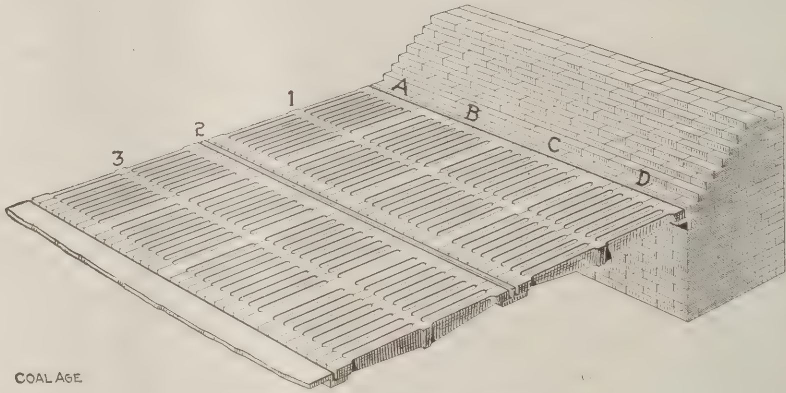
Gage cocks should be kept open and used several times daily. The glass on the water gages should be kept clean and water and steam connections blown out several times daily, especially through the water valve, which is the most liable to become stopped up.

Scale Accumulations

Whatever type of boiler is used, it is absolutely necessary that they should be kept clean inside and out. This may seem obvious and hardly necessary to repeat, but an examination of many colliery plants will soon prove that it is often badly neglected.

If a fire-tube boiler is used, the flues should be cleaned out with a blower once a day at least and the same applies to the outside of the tubes in a water-tube boiler. The frequency of cleaning the inside of fire-tube boilers and inside the mud-drums and tubes of a water-tube boiler, can only be determined by actual experiment or analysis of the water, but by no possibility should boilers be allowed to run longer than the regular time without cleaning.

The accompanying profile shows the enormous losses of fuel resulting from accumulations of scale in boiler tubes, as shown by actual tests made by the Lagonda Manufacturing Co. on a boiler with 2-in. tubes and working under 90 lb. steam pressure. These losses vary greatly according to the character of the deposit, and the results here given are close to the maximum on record with the worst kind of scale.



Sketch of a Boiler Firebox

Operation

The following points should be watched to insure good results and minimum losses:

Boiler settings and walls, fronts and cleaning doors, should be kept in order and all cracks and leaks promptly stopped up. Furnace walls should be kept free from clinkers; baffles and bridge walls in good condition and no accumulation of ashes or clinkers allowed.

Leaks should be stopped at once in all piping and steam pipes should be covered to avoid condensation and loss of heat.

Boilers should be blown out once a day, preferably in the morning.

Safety valves should be tried every morning, to see that they work properly.

Steam gages should be tested once every three months, and they should be kept clean, and placed where they can be easily seen.

The advantages of good draft are apparent. No accumulation of ashes or soot should be permitted that would in any way interfere with the draft, and the breeching and stack connection should be kept tight and clean.

All ash pits should be water-tight and water should be kept in them at all times. They should be thoroughly cleaned out whenever the fires are cleaned and oftener, if necessary.

The necessary tools to properly handle the boilers should be provided and these should be hung up on the walls when not in use.

List of tools: Shovel, rake, two-pronged hook, slice bar, coal pick, T-leveler (made of pipe and used only for leveling top of fire) and a long-handled scraper, for raking ashes out of pit.

General Notes

Coal should be placed in the boiler room within easy reach of fireman, and a hard, level floor should be provided, preferably concrete or vitrified brick. The superintendent should insist on the boiler room being kept clean and no accumulations of scrap, ashes, water, etc., allowed. A water hose and connection to the boiler feed should be provided for wetting ashes and for general cleaning.

The boiler room should be made as light and be as well ventilated as possible, and should have a toilet and wash basin with running water. Experience has proved that these general improvements and facilities pay, as they assist in getting better results and make it easier to get and keep good men.

In the examinations for the position of mine foreman, more attention should be given to power-plant questions and more knowledge required from the candidates since the use and making of power is one of the important questions in mine operation. It is among the mine foremen that we must look largely for our mine superintendents and managers, and the better educated they are on all mining questions, the greater will be their efficiency.

An Improved Mine Rescue Apparatus

Special Correspondence

Oxygen tanks must needs be cumbrous and heavy in order to resist the pressure of their contents. When the oxygen is held in chemical combination, the weight can be considerably reduced. A compound of oxygen and sodium hydrate, which liberates oxygen when water is dropped on it, is used in this apparatus.

The development of self-contained breathing apparatus for mine rescue work has extended over many years. However, the point has been reached but recently where the apparatus could be considered as of any practical value to the mining industry. This is due largely to the fact that a breathing contrivance to be efficient has practically to parallel the functions of the human organism; whereas the body receives oxygen creating car-

Side View of Servus Mine Rescue Apparatus, Showing Mask

bon dioxide, the apparatus must deliver oxygen and absorb the CO_2.

Four qualifications, therefore, are absolutely essential: (1) The volume of oxygen must be ample to meet every requirement, the actual need of the lungs ranging from 0.2 liter to 2.0 liters per minute according to the amount of labor performed by the operator. (2) The absorption of CO_2 must be relatively complete, the volume of this gas thrown off being about equal to the volume of oxygen absorbed, the exact ratio being 9:10. The presence of over 5 per cent. of this gas in the inspired air causes discomfort, and a great percentage utterly unfits the operator for any actual service. (3) The inspired air must be cool and contain the proper amount of moisture necessary to keep the mouth and nasal passages from becoming dry. (4) The apparatus must be light in weight and so suspended on the body as to cause the least discomfort and allow the operator free use of both arms.

Development of Breathing Apparatus

The early types consisted of a helmet and large flexible bag. In the latter was placed a package of flax or cotton waste saturated with a solution of caustic potash. The bag was then inflated with oxygen, and for a short period, the apparatus was of some slight value. The next step was the addition of oxygen in steel cylinders, which was released into the bag either by means of a regular locked feed, or at the will of the operator. This method was fairly satisfactory, but the renewing of the generator meant inevitable delay at critical times when human life was a matter of moments.

The next advance was the production of a sealed regenerator, the capacity of which would be constant for a given period and through which the air was drawn by an injector. This method has proved fairly efficient, but because of the excessive weight of the apparatus, which is due largely to the oxygen cylinders, and because the whole construction and

Apparatus As Seen from Rear, Showine Cooler and Breathing Bag

method of operation are so complicated, it is conceded that this plan still leaves much to be desired. The new device known as the Servus Oxygen Mine Rescue Apparatus, manufactured by the Servus Rescue Equipment Co., of Newark, N. J., has been designed to overcome these objectionable features. In this type

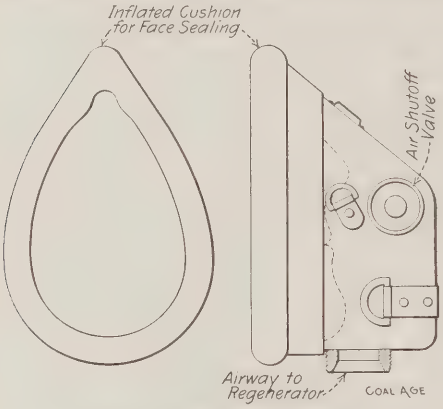
a chemical combination of oxygen with sodium hydrate is utilized, the compound being of such a character that it instantly liberates oxygen gas 100 per cent. pure on the addition of water, exactly as acetylene is released from calcium carbide.

The Source of Oxygen

This chemical, known as Oxodon, is fused into convenient cakes, five of which are used per hour, liberating 130 liters of oxygen and leaving a residue of one kilogram of sodium hydrate, which is used simultaneously for taking up the CO_2, which it accomplishes perfectly. The chemical is placed in a heavy rubber bag and the air passed over it, this bag being also used to receive the air exhaled by the wearer.

Water contained in a cylinder above the bag, is used jointly for generating oxygen and for cooling purposes, principally the latter, the air having to pass over the water when inhaled. A valve controls the starting and stopping of the water drip, but its actual regulation is accomplished by a set adjustment so that the proper flow is assured at all times.

The weight of the one-hour type, completely charged, is but 18½ lb. and of the



Side View of Mask

two-hour type is but 22 lb., the difference in weight resulting principally from the greater amount of water carried for cooling purposes in the latter type.

The lightest action of the lungs provides the necessary motive power to insure perfect and complete circulation, which is directly controlled by two check valves of the mica disk type operating in reverse directions. The exhaled air, after leaving the mask, travels through a noncollapsible tube over the left shoulder down through the cooler into the bag, where the CO_2 is absorbed and the air is replenished with a supply of oygen. After leaving the chemical, the air is passed through a series of tubes surrounded by water which removes the heat caused by chemical action and condenses the excess moisture. The air then passes through the second tube over the right shoulder into the lungs.

The Mouth-and-Nose Mask

It is generally conceded that a helmet which entirely encircles the face, is hot, liable to leakage, and depends for safety wholly upon a rubber pad or an inflated air cushion. Moreover, the wearer is restricted in motion and in vision. The mouth piece, while permitting free motion of the head, is insanitary, prohibits conversation, affords no protection to the nose, and necessitates mouth breathing, with the resultant dryness of the throat so familiar to wearers of this type of apparatus.

A mouth-and-nose mask has been long recognized as ideal, but until recently has been considered unavailable because of

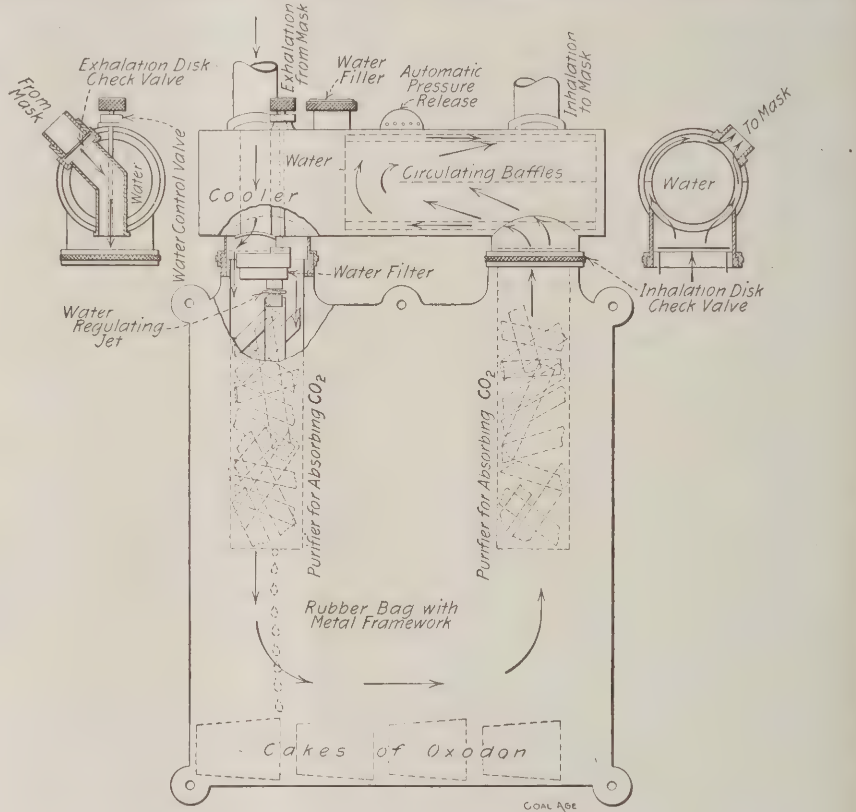


Diagram Showing Mode of Action of Breathing Bag and Cooler

the inability to secure and seal it properly to the face without undue and uncomfortable pressure. The Servus apparatus is equipped with a mask which encircles the nose, mouth and chin and which is retained in position by a special piano wire spring strap, affording a uniform tension at all times without any discomfort to the wearer.

In all other types, face sealing is accomplished by inflating the rubber cushion, and serious difficulty has been encountered from inherent inequalities in the rubber, which permit air bladders to form and burst under pressure, rendering the apparatus instantly unavailable. The wire spring strap provides that a perfect seal can be made between the Servus mask and the face. But to give further assurance, the rubber cushion is inflated by discontinuous pressure on a rubber bulb. A check valve between bulb and cushion provides for the retention of all air thus pumped into the latter. Both air and water are used to make the seal. When no longer in service, the end of the bulb is pressed and the excess pressure in the cushion is released into the bulb. When the mask has been strapped on, ready for use, the bulb is pressed, and the operator forces the air and water into the sealing cushion, the bulb remaining collapsed while the device is in service. This water at the time of manufacture, is made slightly alkaline and thus acts as a preservative to the rubber.

Availability in Service

The rubber bag, which serves both for a regenerator and as a breathing bag, is covered with asbestos and mohair canvas and protected by a substantial metal frame work, so that the operator, when crawling through narrow spaces, cannot readily force out the reserve air, or puncture the bag. In suspending the Servus apparatus, the knapsack idea has been followed, the weight being high up on the shoulders and the pull being directly downward, leaving the chest entirely free from straps.

No costly supply of regenerators and spare parts is necessary. Oxodon, cold water and sodium hydrate are the only requisites for the immediate operation of the apparatus. Oxodon will keep indefinitely without deterioration when sealed in the special containers in which it is supplied. Its action on rubber is specifically preservative.

The Servus apparatus is made in four types: No. 1 is the two-hour type and is designed for heavy labor such as would be required in mines. Weight 22 lb. No. 2 is the same as No. 1, except that it has less cooling surface and slightly smaller

bags. Weight 17½ lb. No. 3 is intended for one-half hour's work only and is of markedly different design. It is placed entirely in front of the wearer and being without check valves, the air travels through two small tubes into the bag and back through the same tubes. This latter apparatus is designed more for fire-department work or for inspection work in mines. No. 4 is a compact, light, emergency mine rescue apparatus, designed for use in smoke or gas, where the rescuers can penetrate to a body of imprisoned men. Each man can carry from one to ten apparatus, and by their aid can enable the endangered persons to travel to a safe place.

They are also designed for permanent storage at strategic points in the mine, where they may be instantly available in the event of a fire or an explosion. The apparatus just described marks an important step forward toward the perfection of rescue apparatus. The positive action of the oxodon, the light weight of the apparatus, its freedom from cumbersome bulk, its simplicity and comfort to the wearer, are some of its advantages. Because of its simplicity, and the fact that it is manufactured wholly in the United States, its cost is not prohibitive and its delivery is not subject to delays.

A New Type of Rivetless Chain

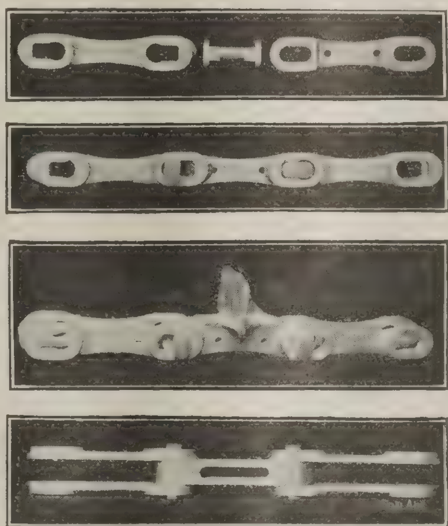
Nearly everyone who has had much to do with elevating and conveying machinery around coal-mining plants, or elsewhere under similar conditions of service, has at one time or another come to the conclusion that no conveying chain on the market was quite right, and has forthwith set out to devise one that would be perfect. The results have been varied, but most frequently disappointing, and of the many forms suggested only a comparativeiv few of proven worth have survived in extensive use.

One demand, however, has always been particularly insistent, and this is for a rivetless chain, one that can be detached and put together without the use of tools and without involving the delays to operation, consequent upon the necessity of cutting out and riveting up a number of pins in case of breakdowns. Several successful chains of this type have been in use for some time, but a new rivetless chain which promises to still further supplant a number of forms of riveted chain, now generally in use, has been patented recently by Joseph L. Lee, general superintendent of the Cross Engineering Co., Carbondale, Penn.

This chain, as shown in the accompanying illustrations, is rugged and simple in construction and is intended primarily for heavy elevating and conveying work. There is but one style of pin and two styles of link—the inside and outside links. The illustrations are almost self-explanatory, but it may be well to quote from the claims made for this new product by its inventor and manufacturers.

The chain is interchangeable in all parts. The parts are easily and quickly detachable, and each section can be detached in less than a minute. The links can be released or removed by a horizontal movement equal to the diameter of the pin, that is, a movement of 1⅛ in. for the 9-in. pitch chain, thus doing away with the necessity of adjusting the take ups when links or pins require renewal.

The chain will operate over either a sprocket wheel or a traction wheel, and is interchangeable with certain other types of rivetless chains. It has a wearing surface on both links and pins which is equivalent to that of the standard riveted eye-bar chain, generally known as the "Scranton" type. The pins of the



New Rivetless Chain and Chain Parts

new chain are reversible, so that after becoming worn on one side, they can be turned through 180 deg. to present an unworn surface for 100 per cent. additional wear and, at the same time, will tend to restore the chain to its original pitch.

A special feature of this chain which is claimed to be a distinct advantage over any other type, is the lip shown on the outside links. Thus, when the chain is in working position, whether passing over a sprocket or traction wheel, the slotted space in the center links, back of the pin, is entirely closed. This feature prevents dirt or gritty material from coming in contact with the wearing surfaces, and, if desired, the recess or pocket may be filled with any solid lubricant, such as graphite or hard grease.

The chain links, being solid, have a distinct advantage over the web or open type of links as there is no compression at any point on either link or pin to cause the chain to part or the attachments to stick, and it is not necessary to remove the attachments in order to disconnect the links or pins. The two center links form a pocket for the insertion of the several forms of attachments required. On the other hand, these links may be reversed and placed back to back for use with side attachments. The links are to be drop forged from 0.30 to 0.40 per cent. carbon steel and broached to assemble with an accurate pitch, and the pins are to be drop forged also, and machine finished. The whole is to be assembled to length in the shop to insure free working of chain parts.

There is just one infallible test for an elevating and conveying chain and that is service under the conditions for which it was designed; but it may be said of this new comer in the field that it has every appearance of being thoroughly reliable, practical, and serviceable and capable of living up to all that is claimed for it. The Cross Engineering company is preparing to manufacture this chain in 4-, 6- and 9-in. pitches and a number of mechanical men in the anthracite coal region are of the opinion that it will find a broad field of application.

On Spanish Needles

Publishing houses are often in receipt of strange and weird communications, but we think the ultimate refinement has now been attained in a recent letter to the *Engineering & Mining Journal*, regarding which it says:

It's hard to keep a good fake down. Out of Darkest Arkansas comes an inquiry for a good, reliable "Spanish needle" for locating gold and silver. It's no use spoiling a thing in the telling, so we offer it in the original orthography and typographical style of the Arkansas hinterland:

April 3+4, 12—To the "Engineering and Mining Journal": I Will now Drop you a few lines to see Wheather or not you all handle eny Spanash Needles en your line of Goods iff you Doe Please Send me your Price list. on them and your Best Turms and I Want one that a man Can Depend on. I Want one that will loe cate Silver or Gold and iff your house Don't handle the Goods Would you Bee able to Give me the name of some furm that Does. Well I Will Remain as ever yours truly ——— ——— By By hoping to here from Soone and a Good Reply.

We chronicled, in the "Journal" of Feb. 4, 1911, the interference of the postal authorities with the Stauffers' thriving mail-order business in "goldometers," "electrometers," and "Spanish needles." We have not since heard of any new school giving "short courses" in gold finding.

This Week's Front Cover

The underground flashlight shown on the front cover of our issue this week is a view taken at the face of a room in one of the mines of the Lumaghi Coal Co., Collinsville, Ill. The coal is of medium hardness and is from 7 to 8 ft. in height. The seam is practically flat. The compressed-air pick machine, or puncher, shown in the cut, was manufactured by the Sullivan Machinery Co.

The puncher is engaged in making a wedge-shaped undercut to a depth of about 5½ ft. The cut is 18 in. high in front and tapers to 3 or 4 in. at the back of the mining. This style of undercut causes the coal to roll nicely when it is broken down, and frequently brings better lumps than when the undercut is made with a chain machine.

The Anthracite Miners' Convention

Special Correspondence

Anthracite miners, in convention at Wilkes-Barre, May 18 accepted the tentative agreement reached some time ago by a subcommittee of miners and operators, and have returned to work. Two separate accounts of the convention, from different points of view, are here presented.

The tri-district convention of anthracite mine workers, in session at Wilkes-Barre, Penn., voted on Saturday, May 18, to accept the tentative agreement entered into by the subcommittee of operators and miners in New York on Apr. 25, and peace is now insured in the anthracite region during the next four years. The vote stood 323 to 64 in favor of acceptance.

President John P. White, and those who were associated with him in arranging the terms of the tentative agreement, stated emphatically and impressively during the course of deliberations that they had secured the best terms possible, and that strike or no strike, further concessions were not to be obtained from the operators. President White's public revelations of the actual condition of the union and its finances were merely an official affirmation of facts known to the operators, to the miners who took an intelligent interest in the affairs of the union, and to every person in the anthracite region, who had gone to the trouble to investigate the situation.

Opposition to the acceptance of the agreement, emanated chiefly from representatives of the foreign miners in the lower districts of the anthracite field. These men knew as well as the more conservative and conciliatory officials, the exact condition of the union and the impossibility of winning a strike if a strike was declared. Moreover, they knew that if the strike was lost, the union would not survive. Yet for several days they fought ratification of the agreement, without having any rational principle to defend or any definite policy to pursue.

Their notion of an adjustment seemed to be that the coal companies were in a position to accede to any raise in the rate of wages, that they might demand, because the operators had it in their power to raise the price of coal indefinitely. Perhaps one of the most valuable results of the convention is that it has brought home to the foreign mine workers a more just perception of the purposes of a union, and the fact that public opinion counts for something in the adjustment of a disagreement between capital and labor, which affects the common welfare on an extensive scale. The disappointment of these men was great, and their personal distress was apparent when in some way they at last came to realize the logic of the situation and that a strike would have been disastrous for them as well as for the union.

The newspaper reports sent out from Wilkes-Barre, during the convention, failed to give a fair or accurate impression of what was there taking place. Newspapers, published in the anthracite region, were conscientiously anxious to minimize the importance of any exhibition of strike feeling that developed during the proceedings, while the representatives of New York and other outside newspapers, were anxious to accentuate the more sensational episodes, making it appear that a strike was imminent. As a matter of fact, from the beginning to the end of the convention, there was not the slightest danger of the tentative agreement being rejected.

All doubt on this score was set at rest by President White's speech. It was not so much what he said regarding the numerical and financial strength of the union, as his strong and emphatic exposition of the merits of the agreement and the results of rejecting it, that in the end caused it to be accepted. John P. White seems to be an exceptionally able man. He dominated the convention, and in my opinion, while in no sense an idealist, he is a better leader than John Mitchell. There is not about him the slightest suggestion of playing to the gallery.

Opposition to the Agreement

Andrew Matti, a district vice-president and leader of the Italian miners, conducted the opposition on the ratification of the agreement. Mr. Matti was rather noisy in an oratorical way, during the first few days of the deliberations, speaking often and to little point. Andrew Ryscavage, another district vice-president and leader of the Polish delegates, was also, at the opening of the convention, a determined opponent of the acceptance of the agreement. Toward the close of the proceedings, however, both he and Matti were eager to bring their followers to accept its terms. In my opinion, and I have attended a number of miners' conventions, at least three-fourths of the delegates to the convention, were determined to accept the tentative agreement at any cost.

Neither the operators nor the miners had anticipated that the general committee of miners would repudiate the work of their subcommittee. A great majority of the miners were indignant at the folly of this action, and it is certain that such an incident will never occur again, if the mine workers of the anthracite region can prevent it. It is now admitted that the committee acted not only illogically, but from the standpoint of the union, illegally in that it had no authority to reject the tentative agreement before its submission to the tri-district convention. This committee delegated its power to a subcommittee and in doing so, its executive responsibility began and ended.

After the convention had ratified the agreement, I asked a very intelligent miner of my acquaintance to give his opinion of the result. "We have secured a raise in our wages of 5 per cent.," he answered after a pause, "and that is all." I pointed out to him that there was a series of other provisions in the agreement that seemed to be of the utmost importance to the miner. He replied that theoretically these concessions were all right, but that a strong union was necessary to secure the full effect, or indeed any benefit, from these provisions and he feared that instead of the union becoming stronger numerically or financially during the next four years, it was in danger of disappearing altogether. In regard to the matter of a checkweighman, he continued, let us take as an example a mine employing 1000 men and boys where the union local numbers perhaps 120 or 130 members. How long do you think these union men will be inclined, or able, to pay the salary of a checkweighman, who is working for the men who do not contribute toward his wages, as well as for them?

There was great rejoicing among all classes in the anthracite region when this convention had come to an end. The mines are in excellent condition, nearly all of them having been thoroughly overhauled and made ready to begin operation as soon as the suspension was called off.

Another Account of the Miners' Convention

The anthracite miners, convinced that the offer of the operators was the best contract they could secure, have decided to return to work and for the next four years will labor under the best conditions they have ever had.

The keen disappointment, which the men felt over what looked to them like very slight concessions, was removed at their convention here. When they settled down to a serious consideration of the proposition, they came to look upon it in a different light and were convinced that the coal operators had gone a long way toward conceding to them, some of the really big demands they had made.

Delegates began to assemble in Wilkes-

Barre on Monday, May 13, and it was plain from their expressions of opinion that many of them had determined to reject the tentative agreement and repudiate their leaders. National President John P. White came here with the sentiment of the men largely against him and with ugly rumors afloat, but he and other leaders were prepared to lead the men into an impassionate consideration of the whole matter.

To bring the question home to the miners, it was necessary for President White to bare secrets of the organization and present the case in its most forcible aspect. In his address on Thursday, by a presentation of plain, undeniable facts he showed the men the folly of their hasty conclusions and the dangers ahead if the convention decided to reject his advice and vote to strike.

President White first discussed the terms of the agreement. He took it up clause by clause and in a most able manner showed the men what each concession meant. It was an easy matter for him to show that the sliding scale was an uncertain factor, and that while it had been the means of securing them some extra money, as a business proposition it was not nearly as safe as a flat advance of 10 per cent. He discussed the awards and concessions, covering every point over which the miners argued and showed that out of 170,000 men in the anthracite field, there were less than 30,000 men in the union. He presented figures which showed that in recent years, the union's ranks had been thinned to 21,000 men and that after many organizers had spent months in the field, there were, at the end of March, less than 30,000 members.

Finances of Miners' Union

From a financial standpoint, President White explained that the organization was in no shape for battle. He presented a statement showing that from 1902 down to last year the balance on hand had decreased from one and one-half million to about \$250,000. He did not say just how much money the national treasury contained at this time, but made it plain that there was not enough money on hand to justify even the thought of a strike.

President White explained that the men of the anthracite region had so far forgotten their union that in the past two years it had been necessary for the national organization to pay back in per capita taxes and loans over \$40,000, to keep the three districts' offices open. He referred to the fact that the anthracite men owed the national organization the sum of \$750,000, which had been loaned during the struggle of 1902, and that there was no means at hand of paying this money back. He declared that if the men did not accept his advice and adopt the agreement, they knew just what they faced and any mistakes made would have to be borne by the men and not by the leaders. He put the situation squarely up to the men and declared that they must decide.

Before his address, there were enough delegates in the convention, opposed to the agreement, to defeat the proposition. When he had finished, sentiment began to change at once. Many of the instructed delegates went back to their local unions to present the situation to them and returned with orders to stand by White and the leaders. From this time on, the result was not in doubt. The men had been convinced.

The leaders were not content to let the proposition go to a vote at once. Other officials were called upon to make explanation of the concessions and tell the men what they faced. National statistician William Green made a splendid address and national board member Frank Farrington and the three district presidents all pleaded with the men to be governed by reason and accept what the companies had offered.

The opposition began to lose its hold, and by Friday afternoon there remained only a few instructed delegates who were willing to vote against the agreement. These delegates declared they would have to vote against the proposition even after they had been convinced that it was the best they could get.

By Saturday all doubt as to the result of the convention was removed. The leaders discovered some anxiety among the men to get back home and suddenly called for a vote. So certain were they that the agreement would be accepted that a standing vote was called for. Those in favor of the agreement numbered 323, while the opposition could muster only 64 votes. The convention came to a close after deciding that repairmen were to go back to work Monday May 20 and the miners on the Wednesday following

The Coal Unloading Terminal at Sewalls Point

By Floyd W. Parsons

It is estimated that the anthracite field originally contained 19½ billion tons of coal. Of this total deposit we have mined approximately 2¼ billion tons, and for each ton marketed another ton of coal has either been wasted or left in the ground. It is evident, therefore, that upward of 15 billion tons of anthracite remain unmined, and that a long period of industrial activity may be looked forward to by those engaged in mining hard coal.

This great deposit of anthracite in Pennsylvania has furnished the chief source of income for nine important railroads. Mining as an industry in northeastern Pennsylvania has caused the building of many large towns and several great cities. If all this has been brought about by the exploitation of a great and valuable coal deposit, history will repeat itself in other states where similar natural resources are found.

Showing Operation of Car Dumper at Sewalls Point. Contents of Railroad Car are Being Poured into the Pier Car

As compared with the immense deposit of anthracite, we have only to remember that more than 20 billion tons of coal lie tributary to any one of several great railroads in southern West Virginia. The Virginian Railway, for instance, must eventually carry such a tremendous tonnage to tidewater, and it is interesting to know the provisions that have been made at the seaboard for handling this great amount of bulky freight.

The coal-unloading terminal of the Virginian Railway is shown in the accompanying photographs. This pier is located at Sewalls Point, seven miles down the main stream of the Elizabeth River from Norfolk, Va. The equipment here installed is one of the largest and best

plants of its kind in the world. The total cost of the installation was more than $2,000,000. Its operation has immensely increased the importance of Norfolk as a coaling station, and Hampton Roads is now the largest coaling port of North America.

The maximum unloading capacity of the Sewalls Point pier is equal to that of all other coal terminals in the vicinity of Hampton Roads combined. Every labor-saving device worth including has been installed, thereby reducing by several hours the time required to load a vessel with either bunker or cargo coal. As a result of the advantageous location of the pier, so close to the main channel of Hampton Roads, the Virginia Pilots Association now brings vessels up at night, as well as by day, so that the pier runs on a 24-hour schedule. It is electrically lighted for the night work. At the back of the terminal is a large receiving yard of 185 cars capacity. The pier is 1045 ft. long and is built entirely of steel on large concrete foundations. Its average height is about 75 ft., above water level.

General View of Sewalls Point Coal Unloading Terminal. Pier Car Is Shown at Top of Incline Approach

The maximum capacity of the pier is more than 15,000 tons per day of 10 hours, or 4½ million tons per year of 300 working days. There are four berths on each side, so that eight vessels, not exceeding 200 ft. overall, can be accommodated. The machinery of the pier enables the handling of a railroad car every two minutes, or not less than 1500 tons an hour. This is done by means of a number of hopper-bottomed, electrically operated shuttle cars—called conveyor or pier cars—each of which receives an entire railway carload of coal at a time, carries it out on the pier, and unloads it through movable chutes into the vessel.

Operation

Upon the arrival of a vessel to take a consignment, the switching engine pulls out from the yard tracks the proper number of cars and places them in the barney yard adjacent to the pier. From this point the cars are emptied and removed one at a time in rapid succession by the unloading equipment.

Each car is run by gravity to the foot of an inclined approach to the car-dumping plant, where it is engaged by an electrically operated barney hoist and pulled to the upper level of the car dumper. After being emptied by the car dumper (which operation is shown in the accompanying illustration), the car stands, until kicked off by the next succeeding car and is then allowed to run down an incline to the empty yard. The operation of the car dumper is to pick up the railroad car bodily from its position on the upper track and turn it completely upside down, so as to pour its contents down over a deflecting apron into a steel pier car of 60 tons capacity, which has meanwhile been brought into position on the lower track of the car-dumping plant. The empty railroad car is then returned to its normal position, ready to be kicked off by the next following loaded transportation car.

The railroad car's load of coal having been deposited in the pier car, the latter is allowed to run by gravity to the platform of a railroad scale, for weighing its load. This scale is automatic and records the net weight directly, and the car immediately passes by gravity to a point where it is engaged by an electrically operated barney hoist and pulled up a 25 per cent. incline leading onto the pier proper. On the pier, the car continues by gravity to the desired point over the vessel being loaded—air-brakes and air-operated dumping door in the hopper bottom enabling the car to be spotted and unloaded quickly through adjustable chutes. The empty pier car then proceeds by gravity and its own motors shoreward, back to the receiving position for its next load.

There are ten pier cars, and each one is fully equipped with the necessary electrical, pneumatic and mechanical apparatus. The bottom of the car is made up of four large circular undercut doors, operated either in unison or independently from a central shaft running the entire length of the car, and controlled from the operator's platform. Opening all the doors frees the entire bottom of the car so that coal cannot become wedged or jammed—a feature of superiority to ordinary hopper cars, which become clogged by freezing in winter and thereby delay unloading.

The use of the self-dumping conveyor cars with electric motors, air-brakes and pneumatic bottom doors eliminates the running of the railroad cars onto the pier, and the time and expense involved in poking clogged coal through the hopper bottoms.

A Timber Puller

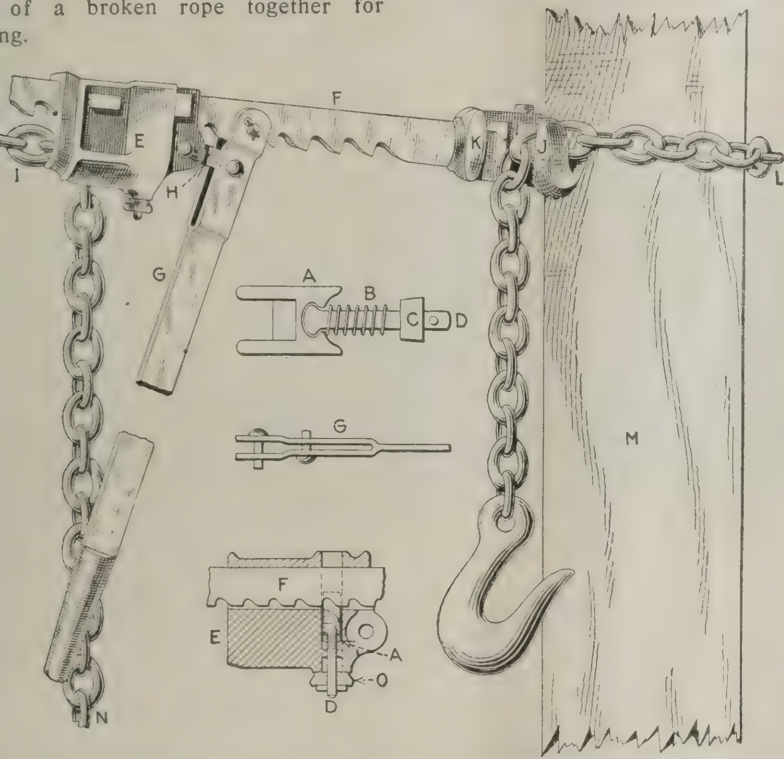
The operation of removing timbers is attended with no little danger. Even when the post is first set, the roof is often none too safe and the operation of driving it into place frequently makes the roof weaker both because of the upward lift of the prop and because of the jarring which accompanies the work. After a prop has stood for some time, the action of the air, the stresses resulting from shot-firing and the general roof strain weaken still further the material which the prop was erected to sustain and it cannot be safely drawn by the use of a sledge because the timberman must stand where the loosened rock cannot fail to fall if the roof is incapable of self support. Yet timber must be withdrawn and a fall obtained if other timbers are not to be burdened more than is safe and desirable.

Safe Timber Pulling

The "Sylat" timber puller furnishes the timberman with a means of withdrawing posts without leaving a place of safety. It will not only dislodge the timber but will drag it toward the operator. Moreover as a steady pull is exerted there is no strain on the roof such as is set up by the hammer blows of a sledge. This simple machine has been used extensively in the coal mines of England and Wales and has been adopted in the United States by some of the larger corporations. Being so simple, the puller

has the advantage of lightness and availability. It can be used in thin and heavily pitching seams as well as in those which are thick and level.

As may be imagined, it will not only pull timbers, but it has beer used for moving heavy mining machines from one cut to another. It has aided in the placing of heavy machinery such as boilers, pumps, hoists, etc., both under ground and above. Where cars have been derailed it has been used to replace or to extricate them. For this reason it is a handy tool to have on hand on a plane where derailments are serious and frequent. Loaded cars are frequently moved with its aid and it can be used with advantage for bringing the loose ends of a broken rope together for splicing.



STYLE OF SAFETY TIMBER PULLER LARGELY USED IN EUROPE

THE "SYLAT" TIMBER PULLER

The "Sylat" timber puller consists of a toothed bar, or rack *F*, about 3 ft. long, having at one end swivel attachment *K*, and a chain block *J* to which a chain *L* (about 3 ft. long) is attached, this chain terminating in a hook. This chain is attached to the anchor post *M*. Sliding on the rack is a block *E*, carrying a ratchet lever and pawl by means of which the block is worked along the rod through the manipulation of a long steel handle or lever *G*. There is another chain *N*, about 15 ft. long, with a hook, which can be attached to the sliding block *E* at any point on the chain by slipping a link into a recess in the side of the block as shown at *I*. This chain is affixed to the post which it is desired to remove.

The pitch of the rack is slightly over 1 in. The length of the lever is such that the pull induced in the chain is thirty-two times the force applied to the lever handle. This pull is sufficient to start and move any timber. When the pawl or catchbolt *A* passes a rack tooth, it is forced in place by a spring *B*; and the lever *G* is then released and moved back one tooth for another pull. It is impossible for the block to lose its grip and spring back. Yet it can be easily and quickly released when desired by moving the lever *G* forward as if to make another stroke. This causes the pawl *A* to ride a rack tooth. While thus released the spindle *D* can be raised by lifting on the cross-bar *C* and placing it crosswise of the recess as shown at *O*.

The device throughout is made of the best grade of materials, with a view to withstanding the hard, knock-about service and frequent neglect or abuse to which almost any mine appliance is subjected. It is extremely simple, has nothing to get out of order or adjustment and can be operated by anyone in the most restricted places.

Western Kentucky Strike Situation

The culmination of the conferences at Louisville, Ky., between the operators in the western Kentucky coal mining district, and the miners, came when the former submitted their "very best proposition." This was taken up several weeks ago at the joint convention of the miners and operators which reassembled at Central City. Pending a settlement of some slight differences, the miners voted for a resumption of work, the ballot being 1850 for and 425 against.

The scale as asked by the miners, and as offered by the operators, is as follows:

	Asked by miners.	Offered by operators.
	Per ton	Per ton
Screened pick-mined coal	$0.925	$0.925
Mine-run pick-mined coal	0.5725	0.5735
	Per yd.	Per yd.
Yardage in pick entries.	1.40	1.40
In wide pick entries....	1.04	1.04
	Per room	Per room
Turning rooms in pick mines	4.18	4.20
Loading in machine mines		
	Per ton	Per ton
On screen-coal basis....	0.4648	0.4625
On mine-run basis......	0.2916	0.2867
Chain machine runners on screen-coal basis..	0.0691	0.0687
Chain machine helpers on screen-coal basis..	0.0617	0.0613
Chain machine runners on mine-run basis....	0.0435	0.0427
Chain machine helpers on mine-run basis....	0.0387	0.0379
Punch machine runners on screen-coal basis..	0.1328	0.1379
Punch machine helpers on screen-coal basis..	0.0839	0.0835
	Per day	Per day
Track layers..........	2.45	2.46
Track layers' helpers...	2.23	2.24
Bottom cagers..........	2.23	2.24
Drivers gathering with one mule............	2.23	2.24
Drivers gathering with two mules	2.43	2.44
Drivers gathering with more than two mules.	2.43	2.44
Riders	2.23	2.24
Water haulers..........	2.23	2.24
Timbermen	2.45	2.46
Pipemen	2.36	2.38
All other inside day labor	2.23	2.24
The minimum outside scale	1.79	1.80
Trappers	0.75	0.76

Michigan Coal Mining

The report of the inspector of coal mines for the State of Michigan states that there were 33 mines in operation during 1908. The average number of employees was 3087, working on an average of 7.8 hr. per day and 20.2 days per month. The total production of coal for the year was 1,839,927 tons. On this basis, 596 tons of coal are secured per year per man employed, or a little under 2.5 tons per day of 7.8 working hours. The oil consumption was reported at 33,966 gal., which is equal to about 11 gal. per man per year, or 0.045 gal. per day. The total amount of powder used was 73,857 kegs, or one keg for every 24.9 tons of coal mined. The average wage was $3.02 per man, and the average cost of mining, $1.67 per ton of coal produced.

As Tate indicated some years ago, when the roof has been continually chipping off over a long period, the top will at last come to rest, forming an arch of parabolic section. When this arch has once formed, it will be more durable and stronger than an artificial arch, or a road that is strongly and expensively timbered, providing there is no subsidence of the supporting pillars. After such an arch has been formed and the removal of the coal is still continued, the parabolic lines may extend upward indefinitely.

The International Red Cross Conference at Washington, D. C.

By M. J. Shields*

The Red Cross Societies of many nations held a conference at Washington, to compare methods of saving lives, and in connection with that convention on May 11 at 2 p.m. held a "first aid" competition and exhibition meet.

The first and leading event was a contest in first aid, in which no less than forty-five teams took part, representing seven different classes of Red Cross first aid work; to wit, the hospital corps of the United States Army, the police departments of the District of Columbia and of the City of Philadelphia, the fire department of that city, the women's first-aid detachment, the miners' first-aid teams, the boy scouts and the field corps of the American Red Cross.

The competition was not general, but teams of each group of first-aid workers competed against other teams in the same group and had separate judges. Those apportioned to adjudge the miners' work were Major Chas. R. Reynolds, Major Matthew A. De Laney and Captain Howard H. Baily of the Medical Corps of the United States Army. I desire to speak in terms of the highest praise of the work of the miners' teams, which received the unstinted praise of the spectators.

Three problems were presented to each team, and in all there were eighteen army and navy officers to render judgment on the work performed. The H. C. Frick Coke Co., the Pennsylvania Coal Co., the Price Pancoast Coal Co., and the Illinois State Mining Department each had a competing team, while the Delaware, Lackawanna and Western Railroad Coal Mining Department showed its enthusiastic interest in life saving by entering no less than three teams.

The following were the winners among the miners: First prize, H. C. Frick Coke Co., a silver loving cup; second prize, Delaware, Lackawanna and Western Railroad Coal Mining Department; third prize, Price-Pancoast Coal Co. Among the mining men present were: J. A. Holmes, H. M. Wilson, Geo. S. Rice, H. H. Stoek, W. A. May, C. E. Tobey, F. H. Coughlin and Drs. Roundtree, Carraway and Head.

A section of a mine was represented, and at 4 p.m. three typical mining accidents were illustrated, a fall of roof, the ignition of a feeder of gas with a naked light, and a fire in a mine. This latter was extinguished by helmet men under the direction of J. W. Paul. The rescue and first-aid work in connection with these demonstrations was illustrated by the Pennsylvania Coal Co.

Other interesting items were an exhibit of the loading of a hospital ship at sea, and an exhibition drill by the Illinois Field Corps of the American Red Cross. The meet was under the charge of Major Chas. Lynch, Medical Corps of the United States Army. Major Lynch and myself desire to thank all those who aided us in making the meet so successful.

*Manager, First Aid Department, American Red Cross.

Miners Ready for Action at International Red Cross Meet, Washington, D. C.

Fuel Movement during First Quarter of 1912

An unusual increase in the volume of coal traffic has been reported during the first three months of the present calendar year, according to a publication just issued by the Bureau of Statistics, of the Department of Commerce and Labor.

Eastern Movement

The shipment of anthracite coal from the Eastern producing territory, as reported to the bureau during the three months of January, February and March, 1912, 18,209,351 long tons, exceeded the shipments during any three months' period in the past decade. Over 25 per cent. of the total shipped, namely, 4,738,476 long tons, was handled in and around New York City for shipment to New York proper and other Atlantic ports. Coastwise shipments of anthracite from Philadelphia during this period totaled 539,855 long tons, while shipments reported from Baltimore were 62,117 long tons.

The bituminous-coal movement in the East during the first quarter of the present year, as reported by eleven leading roads, amounted to 36,818,505 short tons, as compared with 29,019,174 short tons during the first quarter of 1911, 31,773,043 short tons during the same period in 1910, and 23,701,359 short tons in 1909.

The coastwise shipments from the five principal Atlantic seaports amounted to 6,563,411 long tons during the first quarter of 1912, as compared with 6,480,418 long tons during the same period in 1911 and 6,307,403 long tons in 1910. Of the total coastwise shipments for the first quarter of 1912, 2,841,152 long tons were shipped from New York, 928,307 long tons from Philadelphia, 891,456 long tons from Baltimore, 677,133 long tons from Newport News and 1,225,363 long tons from Norfolk.

River Movement

The river movement of coal, on the other hand, shows a much smaller volume during the first three months of 1912 than during the corresponding period in 1911. The shipments by way of the Monongahela River during that period in 1912, 2,105,610 short tons, were much smaller than during the same period in 1911, namely, 2,988,513 short tons.

The river movement during the month of March, 1912, taken as a whole, however, shows a slight increase, when compared with March of last year.

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

The "New Nitrogen" in Firedamp*

It is well known that the "nitrogen" of air is a different gas from that derived from nitrogen compounds, and has a different specific gravity. It was this fact which led to the discovery that the inert gases in air were not nitrogen and carbon dioxide solely, but included argon, krypton, xenon, helium and neon in the following proportion by volume, as determined by Sir William Ramsay. So that overlooking niton, the latest discovery, we have the following composition for air:

PERCENTAGE VOLUMETRIC COMPOSITION OF AIR

Oxygen	20.941
Nitrogen	78.122
Argon	0.937
Krypton	0.000262
Xenon	0.000047
Neon	0.000115
Helium	0.000004
	100.000428

Through M. Le Chatelier, Messieurs Moureu and Lepape presented a paper on the percentage of these rarer gases in firedamp:

"We recently determined the volumetric relations of krypton to argon, of xenon to argon, of xenon to krypton and of argon to nitrogen in a large number of natural gases from thermal springs and in a volcanic gas. These various ratios are extremely constant, and their mean respective values are only slightly higher than those which obtain in atmospheric air.

"Having had occasion recently to study the rare gases found in firedamp, we sought to discover whether they would follow the same law of proportions found in gaseous mixtures of an entirely different origin.

"For this purpose we have calculated the argon-nitrogen ratio of the firedamp samples studied, and, by application of our spectrophotometric method for determining the proportions of krypton and xenon, we have been able to calculate approximately the ratios of krypton to argon, of xenon to argon and xenon to krypton. Further, we have been able to determine the values of the same ratios in a sample of crude argon, obligingly put at our service by M. Th. Schlœsing, Jr., who extracted it from the mine gases of Ronchamp, Anzin and Plat-de-Gier.

RATIOS OF NITROGEN, XENON AND KRYPTON IN MINE GASES TO THEIR RATIOS IN AIR

Source of Firedamp	$\frac{Ar}{N}$ (in mine) / $\frac{Ar}{N}$ (in air)	$\frac{Kr}{Ar}$ (in mine) / $\frac{Kr}{Ar}$ (in air)	$\frac{Xe}{Ar}$ (in mine) / $\frac{Xe}{Ar}$ (in air)	$\frac{Xe}{Kr}$ (in mine) / $\frac{Xe}{Kr}$ (in air)
Lievin, France	1.38	1.4	1.2	0.9
Anzin, France	0.97	1.0	1.1	1.1
Lens, France	1.72	0.5	0.3	0.7
Mons, Belgium	0.82	1.3	2.1	1.6
Frankenholz, Palatinate	0.85	1.1	1.2	1.1
M. Schloesing	0.85	1.0	1.0	1.0

"We see that these numbers in general are quite close to one another and vary comparatively little from unity, which is the value of each of the ratios for air. Moreover, they are all (except three of the ratios, which apply to the firedamp of Lens) comprised between the extreme limits reached by the corresponding ratios of the gaseous mixtures previously studied. It seems permissible for us, therefore, to affirm that the ratios between chemically inert gases are as constant in the firedamps as in other natural gas mixtures. We should recall, in this connection, that Mr. Schlœsing has already observed that the ratio of crude argon to xenon in firedamp varies within narrow limits, and that it is sometimes very near to the value with which it occurs in the air.

Absorption of Rare Gases

"Although the number of samples was limited, we could not fail to observe that the majority of the above ratios were smaller than the mean ratios for natural gases from thermal springs, while the ratios for the Lens firedamp were especially small. This remark leads us to think that in permeating through beds of coal to form, with the methane, the gas we term firedamp, the crude subterranean nitrogen (nitrogen plus rare gases) is selectively absorbed by the coal, and this results in lowering more or less the relative proportions of the heavy rare gases.

"Helium always exists in the *crude* nitrogen of the mine atmosphere, and often in abundant proportions. But its ratio to any one of the other inert gases is not at all regular. We know that this is true also, for the natural gaseous mixtures, and that is explained by the fact that helium is constantly produced by the decomposition of radio-active substances, and these are inequally distributed in the crust of the earth."

*Specially translated by E. P. Buffet for Coal Age.

Supplying Cities with Coke-Oven Gas

In the last five years the German papers have often discussed the project of supplying the larger cities with gas from the coke ovens; but many who have read concerning the project have never considered that coke is really a more important product of coal-gas works than gas. One thousand pounds of coal yield about 160 lb. of gas and 550 of coke, which, as a rule, is sold at a low price to local consumers. The local coke consumption is determined only by the necessary supply; but as the gas production increases as a rule, more rapidly than the population of the cities, there is usually a good supply of local coke at low prices.

But what would happen, asks *Hygiene und Industrie,* if all, or the greater part, of the municipal gas plants of the Rhenish-Westphalian district were to go out of service? There would be no more gas coke, and this would have to be replaced by iron-works coke. But this material, which has only about five per cent. higher heating value than the gas coke, costs thirty per cent. more; and the production depends on the condition of the market. If the cities are to be supplied with gas from the cokeries, the coal mines would have not only the gas monopoly but the coal monopoly as well.

Taking a concrete example—a city with an annual gas consumption of 1,059,000,000 cu.ft., would use up 100,000 gross tons of gas coal and deliver 55,000 tons of coke to local consumers. But if instead of gas coke the furnace coke was used, at $1.25 a ton higher price, the inhabitants would be "out" $68,750 a year; or to put it another way, the 1000 cu.ft. of gas would cost six cents more than where a municipality had its own gas works. So an examination of conditions leads to the conclusion that the municipal gas plants should not be vacated.

Who's Who—in Coal Mining

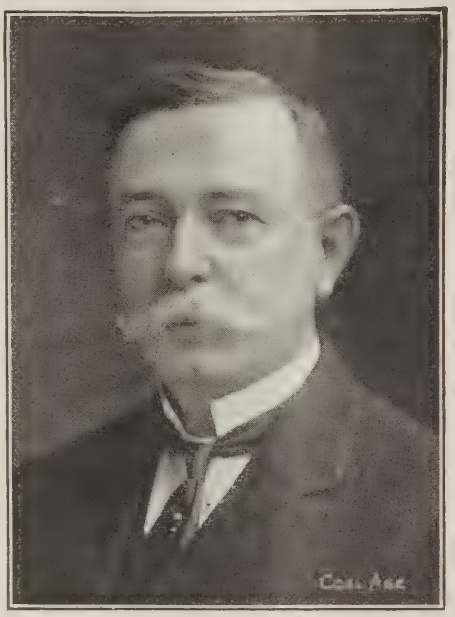
Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

Believing in what you do is half the battle. A man leading a forlorn hope, but who can see only right and justice in his great effort, is likely to accomplish more in the way of execution than the fellow with the easy task whose heart and enthusiasm are not in his work. Earnestness of purpose may not be the greatest asset a man can have, but surely no other personal merit excels it in value. H. M. Chance is sincere and always believes in what he says or does. We don't know that he has ever led any forlorn hopes, but if he has it's ten to one that they were not forlorn when he finished with them. Concentration and serious intent are his chief characteristics.

Born at Philadelphia, Jan. 18, 1856, Mr. Chance was educated at the Central High School, later graduating from the University of Pennsylvania in the Civil and Mining engineering courses, as well as completing special work in geology under Lesley, the father of topographic geology. Immediately on leaving college in 1874, he became an assistant to Lesley, who had just been made State Geologist, and until 1884 "H. N." was located in the iron, oil and coal districts, reporting upon six counties in the western part of the state, and finally preparing a special report upon the mining methods and appliances used in the anthracite coal fields. In 1884-5, Mr. Chance conducted an examination of the Deep River and Dan River coal fields in North Carolina for the State Board of Agriculture, which was then performing the functions of a geological survey.

Having determined to obtain a practical knowledge of the operation of mines, and believing that a mine superintendent should be able practically to carry out the work he is called upon to supervise, he became interested in some iron-ore mines in Lehigh County, Penn., investing most of his capital in the venture. Mr. Chance here gained the experience he sought, but paid for it in time, labor and money. The ore was brown hematite, mined underground and required heavy timbering. It was worth $3 per ton delivered at the furnace. As he had to mine four tons of material to win one ton of ore, and since there were expenses of 35c. for hauling, 40c. for freight, and 25c. per ton for royalty, the profit was nothing unless the cost of mining could be kept at less than 50c. per ton.

Although he succeeded in keeping the mining charges at a low figure, the price of ore at the furnace soon fell to $2, which meant that the cost of mining



H. M. Chance

would have to be reduced to less than 25c. per ton. Having no desire to attempt this impossible task, "H. M." retired from the venture, poor in pocket, but with an experience that enabled him to serve efficiently a firm of tunnel contractors during the next two years as their chief engineer and as assistant superintendent of excavation and construction.

In his study of mining methods while in the Pennsylvania Survey, Mr. Chance became interested in ventilation, in the hygiene of mines, in the effect of pathogenic and dusty mine atmospheres on the men, and in the question of first aid to the injured. This was long before the organization of first-aid corps was effected. In order to grasp these subjects, he commenced the study of medicine, and in 1882 was graduated from the Jefferson Medical College with the degree of M. D.

In 1885 Mr. Chance made some examinations of coal discoveries in Mexico for the Mexican Central Railroad Company. In 1887-8 he conducted an exploration for fuel supply for the Chicago, Burlington & Quincy Railroad Company, finally developing the coal field at Cambria, Wyoming, which was recently described in Coal Age, and which since 1891 has furnished a large part of the fuel supply of that road for its lines west of the Missouri River.

In 1889 he located, selected and developed coal lands for the Choctaw Coal & Railroad Company, tracing the coal from McAlester eastwardly to the Arkansas line, a distance of about 100 miles, and discovering and developing the Grady coal basin and locating the railroad through it. The road was built and the mines were opened and operated successfully under the able management of Edwin Ludlow, until the property was finally absorbed by the Rock Island system.

In 1889 he permanently located at his present headquarters in the Drexel Building, Philadelphia, and has since then been engaged in a general consulting practice in geology and mining engineering. During this period, he has served many of the larger bituminous and anthracite coal-mining companies, especially in the solution of difficult problems, in matters effecting the purchase and sale of properties, in disputes over boundaries, and in arbitrations and appraisals. He has given considerable attention to the supervision of exploratory diamond drilling and other development work to demonstrate values and quantities.

In the boom mining period which followed the discovery of Tonopah, Nevada, in 1901, and which lasted until the decline of Rhyolite, Greenwater and other camps that failed to "make good" about 1907, Mr. Chance was engaged in the examination of minor prospects and a number of metal mines. In all his work as a consulting engineer, he has developed or reported upon coal properties in at least 20 states and territories, iron mines in half as many localities and precious-metal properties in western states and Mexico. In fact, it is probable that no engineer in America has had a wider and more diversified experience than H. M. Chance, and as an authority on the working geology of the United States, few operating engineers are his equal.

He originated the movement that led to the organization, four years ago, of the Mining and Metallurgical Society of America, in which movement he had the warm coöperation of F. L. Garrison, and the benefit of the suggestions and support of Prof. H. S. Munroe, J. F. Finlay, W. R. Ingalls and several other celebrated engineers.

He has been an occasional contributor to various techincal journals, and to the Proceedings of the American Institute of Mining Engineers, Engineers Club of Philadelphia, Mining & Metallurgical Society of America and American Phil. Society, of all of which organizations he is a member.

Correspondence suitable for the columns of COAL AGE solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Entered as second-class matter, October 14, 1911, at the post office at New York, New York, under the act of March 3, 1879.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of Coal Age, we will print 7500 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.

This journal has a direct aim—a single purpose—which is to help advance the coal-mining industry. Its creed embodies the dissemination of knowledge and the free interchange of ideas among its readers, all of whom are invited to become regular contributors.

Contents

COAL AGE

The Anthracite Wage Settlement

The anthracite suspension has ended, and all hope that the miner and operator would emerge from the turmoil with a satisfactory and permanent working agreement was vain. It is true that in an editorial of May 11, we urged the miners to accept the offer made them by the operators, but this stand was taken because it was apparent that some miners were not satisfied with the provision assuring peace for four years, but were desirous of the opportunity of resuming strife with every returning spring.

We cannot congratulate the miner on what he has forced the operator to concede. It is true that his wages have been raised, but he has also obtained, not merely the right to agitate, but also the need for agitation. He who receives a flat wage, which does not change with the flux of economic conditions, which regards neither the ability of the wage to purchase a living, nor the price at which the commodity produced is sold, nor the right of the workingman to benefit by newly developed instruments of production, is bound before long to be dissatisfied and strike.

It was in view of this fact that we had hoped that the miner would have urged successfully an agreement so flexible, so self-molding to all the changes of circumstance, a wage at once scientific and sufficing that the cost of agitation and the wages of unrest would have become as unknown as the desire for protest.

It is the more to be regretted because the defects of the agreement are those which the miner has himself sought through his representatives. If we mistake not, he opposed himself to arbitration, the sliding scale and the conciliation board and prepared himself for a battle, to be followed by four years of skirmishes, foraging expeditions and the like. He has scheduled another battle to take place four years from the present date, so that the air is thick with frays and rumors of war.

This seems perhaps a strong characterization of the labor situation, so much have we become used to "excursions and alarums," especially in the bituminous fields. We have accustomed ourselves to a seething state of agitation and discontent and we do not realize now how uncalled for it all is and how easily it might be avoided, if only a little solid thinking could be made to replace the prejudices which too often animate both parties to the controversy.

The recent quarrel was amicably conducted. What physical violence was shown, was due only in the most indirect way to the action of the union, and it would be unfair to ascribe any blame to that organization. The operators' and miners' representatives met in a most friendly manner and discussed their differences, but while all manner of countesy graced the quarrel, men were idle, the productive energies of coal mining stood still and war is no less war though the combatants are knightly.

From his conduct of the struggle we draw the conclusion that the miner is not seeking stable conditions, but is arranging an atmosphere of discontent, to be followed by biennial, triennial or quadrennial triumphs of discord. The more frequent the disturbances the better he is pleased. Agitation, like machinery, needs more than oiling. It seems generally conceded that the parts must be set in motion frequently in order to secure good results.

How much better it would have been if the matter had been left to a conciliation board consisting of seven members, three representing capital and three labor, and one a competent statistician chosen by both parties. On the latter should devolve the duty of making a continued investigation of the cost of living, and of preparing a special index of cost prices, based on the actual purchases of the average miner. Wages should vary with the selling price of coal, as they have ever since 1903, but they should also increase with the increased cost of living.

Of course, whatever increase in the selling price of coal may result directly from a rise in wages, should not be recognized by a conciliation board as a cause for an increased wage; the tidewater basis should be raised by an amount equal to that increase of wage, whenever the price of labor is adjusted.

We do believe, however, that to maintain the relative level of the miner with other classes of workmen, the wage increment should be dependent not only on an increased selling price, and on the growth of the cost of living, but also, in a rough degree, on the productivity of all labor engaged in the output of those things which the miner consumes. Year by year the time expenditure on articles is reduced because of the invention of new means and facilities of production. In this increased productivity of labor, all should share. In the manufacture of iron, for instance, labor-saving methods have immensely reduced the labor expended. Labor *should* benefit, under past conditions *has so* benefited and, unrestricted, *will* in the future benefit by this improvement.

In fact, the well-being of the European workingman, despite the waning natural resources of that continent, is due to increased productivity resulting from an extensive use of machinery, which use has cheapened the products which he has to purchase. Had the old hand-labor processes been retained, the condition of labor in Europe would have become increasingly distressing.

When the last word is said, the laborer is entitled to a proportionate share of other men's labor. To determine the equivalence of a man's toil is by no means easy, but we think it should be attempted. It might be well tried for ten years, even if after that time a revision might be permitted on appeal of either party. Such an arrangement would be preferable to one which bluntly calls for an agreement on the basis of blind force, followed by unaltered wages for four years, regardless of changing conditions and ending in another test of strength four years hence.

Sulphur in Coal

Our stereotyped methods of analysis do not bring out the condition of the sulphur in coal. The tendency of foreign scientists, however, is to emphasize the importance of that sulphur which is contained in unstable compounds. Many foreign analyses list the sulphur emitted at low temperatures separately in giving proximate determinations, stating what proportion is emitted at or below some definite degree of heat. Anyone taking a whiff of the gases from a newly charged coke oven will realize that the sulphur which is loosely combined is to be found in large quantity in most coking coals. The odor from the oven is much reduced when the charge becomes hot, as the sulphur is not so rapidly emitted at high temperatures after the loosely combined sulphur compounds have been driven off at a low heat.

The sulphur, which is thus loosely combined or entirely free in the coal mass, can be eliminated in coking, and is, therefore, not objectionable as a constituent of a coal prepared for use in the manufacture of coke. On the other hand, it is believed that coal, the sulphur of which is not largely in combination with iron or calcium, may be peculiarly subject to spontaneous combustion. If pure sulphur and iron filings are wetted, covered over with clay and gently heated, their mutual chemical action creates such heat that the resultant emission of steam makes the mass burst with some violence, so that the presence of iron and water would, it would seem, aid in hastening the heating of the coal.

Investigators should study this problem instead of assuming, as is done too often, that pyrite or marcasite is the probable cause of the heating, and, after proving that those minerals are not to blame, decide that sulphur cannot be the cause of the trouble. It is significant that those coals, which have been devolatilized in their early history, forming anthracites and near-anthracites, are not subject to spontaneous combustion.

It is possible that the heat which devolatilized them removed not only the bituminous content, so called, but that part of the sulphur content which was not in combination with iron or calcium, and which was, in other words, not a part of any stable compound.

If the presence of iron in stockpiles of coal aids in heating, as suggested, it might be easy to trace its effects. This theory of spontaneous combustion will explain why water only encourages an incipient fire, and why heating occurs largely where oxidation is clearly at a minimum.

Discipline at Industrial Works

A high efficiency in operation at any industrial plant will be obtained only when a thorough and effective system of disciplining is in force. The employee at such a plant feels intuitively that his efforts are known and appreciated, which is probably the greatest incentive to continued and sustained application that can be offered the average self-respecting man.

To imbue such a spirit in the working personnel at our collieries, the superintendent or foreman must carry an ever-increasing record of each man in his mind. That such records must eventually become confused and lead to serious and reprehensible mistakes in the judgment of the men is inevitable, and every coal official knows the loss of prestige which results from such inconsistencies.

In an effort to overcome this deficiency, the Hudson & Manhattan Co., operating an extensive subway system in New York City, has recently made a radical innovation in this respect. This consists of a system of demeritage, whereby employees are disciplined according to record, the discipline being confined to one of three things—reprimands, demerit marks and dismissal.

Demerit marks are imposed, according to a fixed scale, for violation of rules, neglect of duty, accidents, etc., and when a total of 60 has been reached, dismissal automatically follows. No demerits are inflicted without first giving the delinquent an opportunity to defend himself, and the records are kept private, except as regards the man himself and the company officials.

As an offset to the demerits and an incentive to further effort, there is also a system of merits. Thus an employee receiving no demerits for six months is credited with 10 merits, and in a like proportion for deeds of heroism, loyalty, good judgment in emergencies and suggestions for the prevention of accidents and damage to the company's property. Each merit cancels one demerit.

One of the principal advantages of such a system is that it permits a man who has either wilfully or unintentionally got in trouble to redeem himself. It should also stimulate the employees to exert their best efforts and effect a greater harmony and spirit of coöperation among them.

Thick Vertical Coal Seam

Referring to the question of Charles F. Sherman, COAL AGE, Apr. 6, p. 851, *re* best method of developing a vertical seam of coal, 16 ft. thick, to a depth of 1000 ft. and one mile long, would say I would be glad to answer this question if Mr. Sherman had given the data necessary, in such a case, to enable one to judge of the conditions and arrive at a satisfactory conclusion. Mr. Sherman has failed to state the character of the coal, the nature of the overlying and underlying strata, and to explain the surface conditions and whether the seam is gaseous or free from gas.

After an experience of 25 years in the working of thick pitching seams of anthracite, bituminous and lignite coals, I consider it would be almost impossible to give a satisfactory answer to the question asked without having the above information. To answer the question as it stands, it would be necessary to assume the conditions named above, and the assumed conditions would probably be different from those that actually exist and with which the engineer must contend. The answer in that case would be of no value to him.

J. W. POWELL,
Mine Manager.

Coalmont, B. C., Canada.

In response to the above letter, Mr. Sherman sends the following:

In regard to my inquiry published in COAL AGE, Apr. 6, p. 851, would say that the vein, which is practically 16 ft. in thickness, extends nearly vertically to a depth of about 1000 ft., where it starts to flatten out. The coal is a good hard lignite; and as yet no gas has been found. The hanging wall (roof) is a soft sandstone, while the footwall (floor), at present, is a fireclay, which, however, we expect will be replaced by sandstone, at greater depths. The property is located in a mountainous region, where the surface conditions are very rough.

CHARLES F. SHERMAN.

Farmington, Ill.

Standards in Coal Washing

The article on "Standardization in Coal Washing," by G. R. Delamater, of Denver, Colo., in the March issue of *Mines and Minerals*, gives a complete method of determining the efficiency of washing coal. In the issue of Sept. 29, 1904, of the *Engineering and Mining Journal*, under the heading of "Standards in Washing Coal," attention was called to the lack of any standard methods of determining plant efficiencies, whereby the superintendent of a washery could compare his results with those obtained by others. I believe this subject to be of such importance as to warrant the republication of that editorial, which was as follows:

STANDARDS IN WASHING COAL

Proximate analyses of coal showing fixed carbon, volatile hydrocarbons, sulphur and ash and fuel value in thermal units are of high value to the consumer, and also to the producer, and we hope the day is not far distant when grades will be bought and sold on a guaranteed analysis rather than on the strength of some sort of a trade name. In connection with this matter of coal analysis we call attention to the needs of producers for new data. One of the new developments in the coal industry is the opening of thin seams of poor quality in territory where thicker seams of better quality are not far distant. This development is due as yet not so much to the exhaustion of the good seams as to the high price of good coal lands in districts convenient to our great manufacturing centers and the control of coal lands by great corporations. It is now cheaper in some localities for a newly formed corporation to get title to lands carrying thin, poor seams and use the latest methods of mining and preparing the coal than to get lands carrying coal seams more easily worked and made merchantable. This applies particularly to coking coals.

By washing the coal and by using ovens of improved type excellent coke can be made from seams that show very poorly on analysis. There can be no question, therefore, of a decided increase in the proportion of coke made from washed coal, and in the great extension of coal washing. The matter to which we call attention is the lack of any sort of a standard by which results obtained in washing, particularly in washing rather finely ground coals, can be compared. Analyses of the run-of-mine coal and of the washed coal are valuable, but owing to the variations in the physical structure of coals and the contained impurities, are not sufficient. What the superintendent of a coal-washing plant wants is a standard by which he can make a direct comparison between his work and the work of another man as published in the proceedings of some society or the columns of some mining publication—that is a standard specific gravity test.

It is customary to test the working of washing plants by using solutions dense enough to float coal; in this way the amount of heavy impurity in the washed coal and the amount of coal in the sludge can be determined quickly and with sufficient accuracy for ordinary purposes. The trouble is, when it comes to comparing results, that most papers on coal washing do not state what was the specific gravity of the fluid used.

While it is not possible to use fluids of the same density for all coals, yet it is highly desirable that the specific gravity of the fluid used should be stated. We call the attention of the superintendents of coal-washing plants and manufacturers of washing machinery to this important matter.

The method outlined by Mr. Delamater seems to follow along the lines suggested in that editorial, as all of his formulas are based upon the specific gravity or the float-and-sink test, as he terms it.

I think that the one great value of Mr. Delamater's method is that the separations are made in an exactly similar manner to that which must be employed in the actual washing of the coal, with the exception that a specific-gravity bath is used for making the float tests; this method Mr. Delamater assumes to be the only one having an efficiency of 100 per cent.

However, I should be glad to have the opinion of other readers on this subject, and if any have better methods to suggest, I hope they will be allowed to make use of the columns of COAL AGE to present them. Discussion by those familiar with the subject should result in a standard method being adopted which will be of great assistance to all engaged in this work, and, I think, will go a long way toward the attainment of a higher efficiency in the washing of coal.

It is certainly better to know exactly what one is doing in comparison with others, and I do not think this has been possible in the past with no standard methods of determining efficiencies.

New York City. S. T. A.

Mine Car Construction

I was interested in Mr. Shurick's article on mine cars, COAL AGE, May 11, p. 1008.

The chief requirements for good mine cars are strength, lightness and durability. Where the gradient of the road is not heavy, and the load to be carried does not exceed 1500 lb., wooden cars, strengthened by flat iron bars, give good results. They will stand a fair amount of rough handling, are easily repaired and are not so easily knocked out of shape as iron or steel cars. They are also much cheaper to build than other forms of mine cars.

Red Lodge, Mont. B. H.

Inquiries of General Interest

All Questions Must be Accompanied by Name and Address—Not for Publication

Coal and Mineral Pitch

Are deposits of pitch very commonly associated with the coal measures; or what is the origin of this substance and where do the largest deposits occur? Is there any large quantity of coal in the Philippines?

PROSPECTOR.

Boulder, Colo.

[Pitch is the black, viscous residue that results from the distillation of coal tar and other bituminous substances. Mineral pitch (asphalt) occurs naturally and is the result of the evaporation of petroleum, which has escaped through the pores and crevices of the containing rock strata, into the atmosphere. The occurrence of petroleum and pitch deposits is not necessarily associated with the coal measures, although their modes of formation and origin are analogous. The petroleum-bearing rocks are the sandstones and limestones, but not commonly the shales.

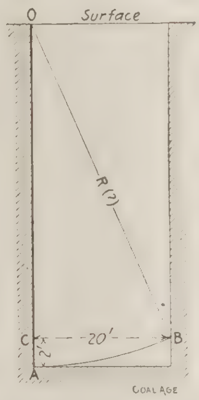
The same metamorphic agencies of heat and pressure that operate to change bituminous coal into anthracite, also assist the evaporation of petroleum and the production of asphalt or mineral pitch. The large deposits of pitch found in Mexico, California, Venezuela, Trinidad, West Africa, Borneo and Russia testify to vast quantities of petroleum which have escaped into the air. The composition of the residual pitch varies according to the degree of oxidation and evaporation of the oil.

Pitch is often found in conical masses from a few inches to 50 ft. in height. Each cone is symmetrical, and while the outside is hard and dry, the center is a little crater from which the flow has occurred. The largest pitch deposit in the world is Pitch Lake, Trinidad. This covers a quarter of a square mile.

As far as has been discovered up to the present time, there are four principal seams of coal in the Philippine Islands, all bituminous. These deposits, it is believed, amount to many millions of tons. The coal deposits in these islands is of increasing commercial value; and its importance to the United States as a coaling station cannot be overestimated. The field is as yet wholly undeveloped and unexplored, and for this reason no accurate information is obtainable relative to the depth or extent of the deposits. In this connection the article published last week, COAL AGE, p. 1054, will be read with interest.—EDITOR.]

A Shaft Problem

Please give a solution of the following problem in COAL AGE, as soon as you can: A bob attached to a string is suspended from the top of a shaft 20 ft. wide, and just touches the bottom. When the bob is swung to the opposite side of the shaft, as shown in the accompanying sketch, it lacks 2 ft. of touching the bottom. What is the depth of



SHOWING CROSS-SECTION OF SHAFT

the shaft? This question has caused considerable discussion here and a great many different answers have been given. We would therefore like to have the correct solution and the rule for obtaining the same.

Johnston City, Ill. R. R. HUDSON.

Assuming that the string is attached to the side of the shaft, at the surface, as represented in the sketch, the question involves a simple geometrical principle.

The depth of the shaft (OA) is the radius of the arc (AB) described by the bob. The sine of this arc is $CB = 20$ ft., and its versed sine $CA = 2$ ft. But, from a simple principle in geometry, calling the chord of the arc AB instead of the arc,

$$(AB)^2 = 2\,OA \times CA$$

$$OA = \frac{(AB)^2}{2\,CA}$$

But

$$(AB)^2 = (CA)^2 + (CB)^2$$

Hence

$$OA = \frac{(CA)^2 + (CB)^2}{2\,CA}$$

To find the depth of the shaft, in the present case, substitute the given values in the last equation: $CA = 2$; $CB = 20$; and

$$OA = \frac{2^2 + 20^2}{2 \times 2} = 101\ ft.$$

Drawing Pillars

I would like to call attention to what seems to me may be an oversight in the illustration on p. 981, COAL AGE, May 4, showing a good system of drawing back pillars by machines. It seems to me that since the entries, in this case, have been driven to the boundary and the work is all retreating, the rooms should be widened on the other side, or outby, so as to make the road and the straight rib on the inby side of the room. I want to ask if, in drawing the pillar between rooms 30 and 29, you would not lose the next one between rooms 29 and 28, and would not this be the case the entire length of this entry; would not every alternate pillar be lost? Should not the rooms, in this case, be widened on the outby rib?

PENNSYLVANIA FIREBOSS.

Hites, Penn.

[The usual plan is to widen the rooms on the far rib, in the direction of advance. In the present case, the work being retreating, the rooms, by the usual method, would be widened outby instead of inby as shown. The question, however, is open to argument, and can only be properly decided, in any given case, by the prevailing conditions of roof, floor and coal. With a fair roof and bottom and good coal, if a systematic method of timbering is preserved, there is hardly any question but that better coal will be obtained by working the pillars from the side toward the falls. The crush on the pillars will not then be as great as when the pillars are cut from the other side and worked toward the falls. In the latter case, the last end of each little stub would be badly crushed, if not wholly lost, and a heavier roof fall might be expected to follow its extraction, endangering the work.

In considering the question, regard must be had to the line of break following up and paralleling the line of pillar work, and unless conditions prevent doing so, the pillar coal should be worked back constantly away from the falls. The same principle holds here as when the pillars are worked back on end; or as in longwall retreating. Under some conditions, however, it would be necessary to work the pillars from the outby side or away from the falls, and get as much as possible out, leaving the rest.

The question is open to argument and we gladly invite its free discussion by our readers.—EDITOR.]

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Iowa Examination for Mine Foremen Held at Des Moines, April 9-10, 1912

(Selected Questions)

Ques.—What should be the volume of air for a mine producing 1000 tons of coal per day, and what would be the effective horsepower of the ventilator, with a 1-in. water gage?

Ans.—The number of inside employees corresponding to this tonnage, basing the estimate on the last Iowa report, would be about 650 men and, say 20 mules. The minimum volume of air required by the Iowa mine law would then be

Air for men	$650 \times 100 = 65{,}000$	cu.ft. per min.
Air for mules	$20 \times 500 = 10{,}000$	cu.ft. per min.
Total...............	75,000	cu.ft. per min.

The effective horsepower for this circulation, under a 1-in. water gage would be

$$H = \frac{75{,}000 \times 1 \times 5.2}{33{,}000} = 11.8\ hp.$$

Ques.—What plan would you adopt to fix a water gage at the intake to indicate the mine resistance where a furnace is used?

Ans.—In order that the water-gage reading shall indicate the total mine resistance exclusive of the shafts, it must be placed on a brattice dividing the main intake from the main-return airway. In case the mine is so arranged or the furnace shaft so located that this is not possible, the reading may still be taken so as to show the difference of pressure between the main-return airway, at the foot of the furnace shaft and the outside atmosphere, by connecting one end of the gage glass with a pipe leading to the surface; or the reading may be taken on the surface by connecting the gage with the closed mouth of this pipe leading down into the mine. In any case, the gage must be so placed and connected that its two arms will be open, respectively, to the main-return airway, at the foot of the furnace shaft, and the main-intake airway, or the atmosphere. In the latter case, the reading obtained would include the resistance of the downcast shaft, in addition to the mine resistance.

Ques.—How should a stable in a new mine be constructed and ventilated?

Ans.—The accompanying diagram (Fig. 1) shows one of many good arrangements for a mine stable at the shaft bottom.

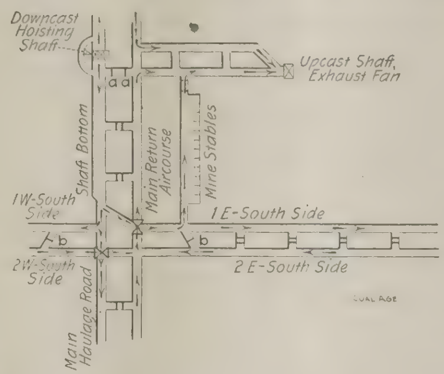


FIG. 1. SHOWING LOCATION OF MINE STABLES AT SHAFT BOTTOM

The principal points to be considered in the location of a mine stable are the following, in the order of their importance: 1. Easy access to shaft or slope bottom to facilitate the handling of the daily supplies and refuse between the surface and the stable, and the rescue of the mules in case of accident. 2. Good ventilation, water supply and drainage. 3. Fireproof construction and electric lighting, or protected lamps. 4. Ready access by good roads to the several districts of the mine. 5. Ample protection from roof falls, squeeze or creep.

In the plan shown in Fig. 1, the stable is located in the solid shaft pillar, between the intake airway of the first pair of cross-entries and the main-return air course leading to the upcast shaft. This arrangement allows an unobstructed entrance on the 1-E cross-entry. The other entrance leading to the main-return airway is protected by the two iron regulator doors, which control the "scale" of air taken from the fresh-air current on the 1-E entry, and afford ready access to the air shaft and the north side of the mine; or, by the double iron doors *aa*, to the main hoisting shaft. A 40-ft. pillar of solid coal separates the stable from the main-south-return air course. The floor of the stable is concreted and drains into the main sump at the shaft. The stalls and other fittings, as far as practicable, are of iron. The stable is furnished with a good supply of drinking water for the mules, and is equipped with fire extinguishers, hose and pipe-line attachments at points sufficiently protected and numerous that one or more of these will be available in case of need.

Ques.—What does a low water gage, with a large quantity of air passing, indicate?

Ans.—This condition indicates an economical expenditure of power to the extent that the ràtio of water gage to quantity approaches a minimum for that mine.

It shows a large air volume per unit of power expended. It shows a comparatively small rubbing surface per unit of *area of passage* or the total sectional area of all the splits combined. It shows a comparative freedom from falls or other obstructions in the air courses, and an ample size of breakthroughs in rooms and entries. Such a circulation approaches the ideal.

Ques.—How would you proceed to turn a cross-entry at right angles to the main entry without using a compass?

Ans.—Suspend a bob from each of the two respective points or stations A and B (Fig. 2) of the entry survey.

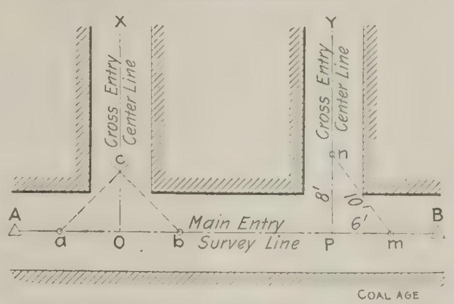

FIG. 2. SHOWING TWO METHODS OF SETTING OFF A RIGHT ANGLE WITHOUT USING A COMPASS

Stretch a string carefully in line with these bobs or points. By means of this string, line in the points O and P opposite the centers of the respective cross-entries. Also line in the points a and b, respectively, at any convenient equal distances, on each side of O. Then from these points a and b as centers and with any fixed radius ac, greater than aO, describe in turn the intersecting arcs which determine the point c and the line OX at right angles to AB. These lines can often be laid off with chalk on the roof, but the work requires care.

In a similar manner the triangle Pmn may be laid out, using the numbers 3, 4, 5 or any multiple of these more convenient, as 6, 8, 10 ft. This gives a right triangle, because

$$6^2 + 8^2 = 10^2$$

and makes the line PY at right angles to AB.

It is important to remember that all measurements must be made in the horizontal plane for any angle other than a right angle, which can be laid out on the pitch.

For the Betterment of Living Conditions in Mining Communities

The New Dangers of the Pittsburg Coal

BY SIM REYNOLDS* AND W. H. REYNOLDS

Despite the work of the Bureau of Mines, of the state mine inspectors and of the technical journals, we find a dangerous adherence to old beliefs and a reluctance to accept new light on industrial problems. I recall an old practical miner, who went down to the Bruceton experimental mine. His features bore the inevitable blue stamps of the practical miner, and his knuckles, stiff and calloused, showed how long an acquaintance he had had with actual mining work.

He had been sent to Pittsburg "to see what the Government chaps were up to anyway," and he arrived seemingly determined to accept nothing on faith, nor was he prepared apparently to accept the tests and statements of more scientific men than himself, no matter how conclusive their theories might be—to them. This old mining official had, perhaps, many a time sought a "cap" in his burnished Davy, years before we were efficient to the point where we could open and shut a door on the main haulway. As he ambled about, he convinced us that there still existed, if not among the younger men, at least among many of the old school of mine officials, who are equally charged by the state with the care of many human lives, such a narrowness of mind and viewpoint, as is certain at some time or other to be the cause of a disaster.

In this particular instance, the man had evidently been sent by his employer to witness the demonstration. He passed through the mine previous to the explosion, and at frequent intervals made tests for methane. This not being in evidence, the old man very carefully examined the coal dust lying on the shelves, and even took the additional precaution to gather a handful, placing it in an envelope with deliberation and distrust. This dust he carefully sealed and put away for further examination.

"There may be something in it besides coal dust," said he, doubtfully. And after waiting for the "blow-up," while the first few ineffectual attempts were made to set the blast off, he added: "If there is nothing in the stuff but just dust, I would not be afraid to light the shot with a squib and sit around the rib corner until it goes off." But we are inclined to the belief, that when he saw what happened when the mine did really explode, the old mine boss changed his opinion somewhat.

*Pittsburg-Buffalo Coal Co., Marianna, Penn.

How Conditions Have Changed

The main difficulty with which we have to contend, is that many men fail to understand how the nature of the work in the Pittsburg coal has changed from earlier years. The Pittsburg bed, in the portions of the field which were earlier developed, is exposed in extensive crop lines along the banks of many rivers and streams.

Consequently the coal has had an opportunity to lose the gas, naturally contained in it, so that where so exposed it has been robbed of its principal element of danger. The time has come when the deeper developments of the Pittsburg field are made or are being made. The parts now mined and to be mined are many of them 500 ft. below the level of the valleys, and under the higher hills they are at least 1000 ft. deep. Consequently the coal has not had a chance to emit its explosive gases and more care will have to be taken in the newer mines for this reason.

Old-time Shooting

But there is another danger which does not appear to be generally understood. Where the measures were more shallow, the coal could be dislodged by light shots, but now a very much heavier charge is needed in order to shoot down a cut of coal. It is true that in earlier days, a heavy charge was sometimes used to bring down the thick plate over the top of the coal bed, so that there might be room for hauling where a part of the seam was too thin for working without that provision, but only the lightest of charges were used to bring down the coal.

These roof charges, though heavy, were probably not as great a source of danger as shots in the coal itself. Even when a shot placed in the rock strata failed to work and a "blow-out" resulted, its destructiveness was at the initial point nullified to a great extent by having nothing but rock dust to work in. We have worked in mines in the Pittsburg district where thousands of rooms were commenced and finished without the use of a drill and hence without powder or other explosive.

Consequently we have seen such mines operating day after day with coal dust from an inch to six or eight inches thick lying over every rod of the entry for miles with every projecting ledge and every square yard of surface in the rooms covered with that explosive substance. But nothing untoward happened, or we would not be recording this condition.

It is hard to convince the fire bosses, the foremen, the miners even, who have year after year been as familiar with this dust as a three-year-old boy is with mud, that there is any danger in it. They will strenuously aver that in places where they have worked from boys up, there have been acres and acres of such dust-laden workings, and no efforts whatever were made to remove or dampen it, and no accident happened as a result.

Present-day Shooting

Of course not, how could anything happen? Coal dust without heavy shooting and without something in the way of a gas or electric combination is certainly innocuous. But in view of the later development in this same field, we shudder to think of the consequences which would possibly have followed a good "solid shot," containing from one to two 5-lb. cans of powder, such as are fired in some of the mines in which we have worked.

Between such mines and a shaft which reaches the deeper and more gaseous portions of the bed, there is a vast difference; the difference existing between the early years of coal dust and no disasters and the years of smaller quantities of dust and disaster. The failure to distinguish properly between the new conditions and the old is a phase of the human element in mining, which has cost dearly in more ways than those specified.

Medical Treatment in Belgium

In Belgium it was found necessary to take a step in paternal legislation in order to rid the mine workers of ankylostomiasis. At first the men who were infected were induced to quit work occasionally for a day in order to receive treatment, but the work done in so short a time was not satisfactory and it was ultimately decided to spread the treatment over a longer and more continuous period. This made it possible to use less violent vermifuges. Wintergreen oil and oil of eucalyptus in most cases then took the place of thymol and extracts of male fern.

While the men were undergoing treatment they received 30c. per day from the provincial funds and usually the coal companies paid 39c. per day additional.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

The Interstate Commerce Commission has rendered an opinion in the case of the Association of Bituminous Coal Operators of Central Pennsylvania versus the Pennsylvania R.R. Co. In this case the complainant attacked the defendant's present rate on bituminous coal from the Clearfield district of Pennsylvania, to South Amboy, N. J. Upon the facts disclosed by the record, it was held that "there has been no unjust discrimination as against the Clearfield operators practiced by the defendant carrier, nor does it appear that the rates attacked are unreasonable."

The opinion is lengthy and includes an historical survey of the situation as to coal rates in the district referred to. Finally the Commission reaches the conclusion that:

It is clearly beyond the power of the Commission to reduce the Clearfield rate upon the ground urged by complainant. It may well be that in times past rates from this and from other fields have been adjusted with relation to the cost of mining coal and that the carriers undertook to make a rate upon which all producers would be brought into competition at common markets and rates so adjusted as to leave to the coal operator a reasonable profit upon his investment. Those rates would fluctuate not with respect to the cost of carriage nor to the value of the service as such, but solely with respect to the needs or advantages of the shippers. Upon the shipper favorably situated in location, and having a thick vein of coal at a slight depth and resulting cheap cost of operation, a higher rate would be imposed than upon his neighbor who might suffer under the disadvantage of a high wage scale and a thin vein. It has been repeatedly said by the Commission that it was not our function, nor that of the carriers, to equalize economic conditions. In this case it fairly appears that the profits made by the Clearfield operators upon tidewater coal are slight, and that if rates should be made so as to sustain an industry which because of intense competition within itself, or because of local disadvantages, yields but a slight profit, the present rate should be reduced. But we do not understand the law as permitting us to fix a reasonable rate solely upon this ground.

Alaskan Coal for the Navy

Congressman Booker has offered a bill designed to bring about the use of a part of the Alaskan coal supply as fuel for warships. The bill is intended "to provide for a permanent supply of coal for the use of the United States Navy and other governmental purposes, and to provide for the leasing of coal lands in the Territory of Alaska."

The Secretary of the Interior is authorized to "lease to any person above the age of 21 years who is a citizen of the United States, or any association of such persons or any corporation organized under the laws of the United States, any of the lands in the Territory of Alaska to which patent has not been earned or to which equitable rights have not been acquired and which contain deposits of coal or lignite, under such restrictions and upon such terms as in his discretion will best serve to develop the fuel resources of Alaska and which shall protect the interest of the public in such resources. And all such coal lands in Alaska are hereby reserved from entry except as provided in this Act, and except as to other forms of entry not inconsistent with coal leases."

Secretary Meyer recently appeared before the Naval Affairs Committee of the House, and suggested that the government consider a plan to use the Alaskan coal for United States naval vessels on the Pacific. The Booker bill is intended to take cognizance of this suggestion as follows:

The President of the United States is hereby authorized to reserve such tract or tracts of coal lands in the Territory of Alaska as may be deemed sufficient to meet the requirements of the Government of the United States and to provide for the mining of coal in the same for the use of the Navy and Army and for other public purposes: Provided, that if any part of the lands so selected be equitably claimed by any person or persons, under rights of location or otherwise, the Secretary of the Interior is authorized to secure cancellation of such claim by a return to said claimant of the expenses incurred by him on account of such claim, or by giving such claimant a preferential right to a lease upon lands of similar value in some other locality, or by both of such considerations, wherever such negotiations shall fairly determine the rights of the parties and secure to the Government such land as its use may require.

Alabama

Birmingham—About 10,000 acres of coal land, near Warrior, are being developed by the American Coal Corporation. The Louisville & Nashville R.R. is building a branch to the property An output of from 1500 to 2000 tons a day is contemplated.

It is announced that the Bureau of Mines will reopen its mine rescue station at Birmingham, July 1, with C. H. Brown in charge. At that time instruction in mine rescue work will be resumed. Mr. Brown, who was previously in charge of the station, was called to Pittsburgh on Apr. 1.

Colorado

Denver—The suit of the U. S. Government against the Colorado Fuel & Iron Co. was heard recently in the district court. In this case, the government questions the right of the coal company to hold land, valued at $3,000,000, on which stands its Primero mine, the largest producer and the best paying property of the southern Colorado coal fields. The Colorado Fuel & Iron Co. is seeking by demurrer to prevent the government from asserting title to the land, which it claims was obtained by fraud. The question raised by the C. F. & I. Co. is new in coal-land litigation. It seeks to have the government precluded from asserting title because the company already has had two adjudications by the land-office officials in its favor. The government makes the unique plea that at the time of these land-office hearings it was not able properly to present its case because the facts as to the kind of land involved were concealed and it did not have an opportunity to obtain a hearing on the real merits of the case.

Reports from Louisville and Lafayette show that more or less violence continues to take place in the northern coal fields, consisting chiefly in attacks on nonunion miners by striking members of the miners' union.

Illinois

Bloomington—A fire, which was discovered in the mine of the McLean County Coal Co., near here, May 9, got beyond control, and the workings have been sealed up. Twelve mules were taken out but four perished in the mine. Flames had spread from the second to the third level before being discovered, and it is thought the loss may be heavy. The mine will be closed for a month.

Princeton—The mines of the Spring Valley Coal Co., at Seatonville and Dalzell, as well as the mines at Marquette and Ladd, have been opened, but the two mines at Spring Valley will not resume work for perhaps two or three weeks, on account of repairs that are being made. Rumors of an indefinite suspension at the two Spring Valley mines have been denied by the coal company.

Harrisburg—Mines of the O'Gara and Saline County coal companies in this vicinity have resumed operation, although the outputs so far have been small. The Big Four R.R. has about finished cleaning up the huge pile of coal which it had stored here, amounting in all to some 87,000 tons.

Waterloo—St. Louis men have taken options on about 300 acres of coal land, near Millstadt. The seam runs 6 ft. thick, and it is understood that the property will be developed.

Springfield—Following the agreement of the miners to return to work, only a few mines in this vicinity resumed operations, and those which did start up employed only about one-half their regular force. Mines of the Lincoln Park, Cora, Jefferson and Chicago-Springfield companies remained closed.

Kewanee—Drilling operations, which have been carried on lately east of here, on the property of the Kewanee Coal Co., have proved disappointing, and the project of sinking a shaft will be abandoned. It was hoped to find the Spring Valley seam at least 36 in. thick in this locality, but the last hole disclosed a thickness of only 17 inches.

Vilia Grove—A 6-ft. seam of coal was struck near here recently by the Douglas Oil & Gas Co., while prospecting for oil. The coal lies at a depth of about 300 ft., and is overlaid by a 26-ft. stratum of slate, promising an excellent roof for mining purposes. It is thought that the oil company will take steps to secure the coal rights on the property.

Indiana

Terre Haute—With practically only one question—that of the weekly pay day—preventing an agreement, the joint wage conference of operators and miners adjourned, after a 3-days session, until May 20. No action has been taken on the six demands set forth by the miners, but according to statements of both operators and miners, the matter of adjusting a contract hinges entirely upon the settlement of the demand for a weekly pay. National officers of the United Mine Workers' organization have expressed the opinion that unless the Indiana miners can prove beyond doubt that their demand for a weekly pay will not increase the cost of producing coal, it is in conflict with the provisions of the Cleveland agreement. An effort is being made to unionize all the men working at the stripping operations in the block-coal field. They number about 500 in all. A meeting of the miners and operators of this district will be called to take action on a wage scale as soon as District 11 has reached an agreement.

Brazil—The German Coal Co. and the Bee Ridge Coal Co. have signed an agreement with the miners, acceding to the demands made by the miners' union, and have resumed operation. Neither of the mines employs many men and most of their output is used by local consumers.

Iowa

Des Moines—A tentative wage-scale agreement was submitted by the subcommittee to the general committee of operators and miners, which reconvened here, May 14. It was understood that all points in dispute had been satisfactorily covered.

Perry—An extensive new coal field will be opened up for development a few miles south and east of this city during the summer. The seam is several feet in thickness and of a superior quality. It is thought by miners that the new field is a part of the seam which crops out at Ogden and points further north, and not a part of the field now operated in this county, near Madrid.

Dallas—Development work on the Indiana Consolidated Coal Co.'s shaft, in Dallas Township, was resumed recently. The combination air shaft and manway will extend to a depth of 65 ft. Work on the new Rock Island road, in the southeastern part of Marion County, known as the Carlisle-Allerton cutoff, is being pushed with all possible speed. That portion of the line near the Indiana Consolidated Coal Co.'s mine is practically finished.

Kentucky

Louisville—Coal operators in Kentucky are keenly interested in the improvement of transportation facilities which will enable them to get into central freight association territory more easily and are following closely all new work of the railroads. That preparations are being made to render better service is evidenced by the completion of the Kentucky & Indiana bridge at Louisville; the prospective construction of a bridge near Paducah, by the Burlington and other lines; the rebuilding of the Pennsylvania bridge at Louisville, operated by the Louisville Bridge Co.; the construction of a bridge by the Owensboro & Rockport Bridge & Terminal Co., which has given notice of its plans for building at a point between Owensboro, Ky. and Rockport, Ind.; and the reconstruction of the bridge of the Norfolk & Western near Kenova, W. Va.

W. C. Black and Jesse Turner have leased a coal property on Straight Creek, in Bell County, and will put it in operation at once. They have announced that the capacity of the mining plant will be considerably enlarged.

Boxley & Co. have begun the construction of a 20-mile section of the Williamson & Pond Creek R.R., the contract for which was recently awarded them. A number of subcontracts for grading and tunneling have been let, and a big force of men has been put in the field. Meanwhile the Pond Creek Coal Co. is pushing development work on its coal property.

Pineville, Ky.—The Continental Coal Corporation, which was formed a year ago for the purpose of taking over a number of operating companies in the Straight Creek district of eastern Kentucky and Tennessee, recently gave a banquet here to the employees of its operating and commissary departments, celebrating the first anniversary of the company's organization. Fifty-six were present. White L. Moss, vice-president and general manager of the company, was toastmaster.

Barbourville—The Knox County Coal Co., which was recently organized with $250,000 capital stock, will have its chief offices in Lexington, and will proceed with the development of coal lands in Knox County.

Ohio

Columbus—Attorneys for the New Pittsburg Coal Co., operating mines at Nelsonville, along the line of the Hocking Valley R.R., appeared before the Interstate Commerce Commission May 15, in an effort to obtain a readjustment of rates to Lake Erie ports. The present rate is 75c. and the company is contending for a reduction of 30c. per ton. It is alleged that transportation costs of the railroad company do not exceed 40c. per ton, and that 37c. is a fair average. The commission made an exhaustive examination of the case and an early decision is expected.

After a ten-days session the joint conference of operators and miners of the Hocking sub-district, the basing territory for Ohio, adjourned May 15, having reached a complete agreement. The contract which has been signed, consists of 35 sections. It goes into every detail of the working conditions and will have an important bearing on the settlements reached throughout the various mining fields of the state.

Bridgeport—A deal was closed here May 16 whereby the Woodsfield Coal Co., of Fairmont, W. Va., purchased from W. R. Hawkins and R. L. Hoskinson, of Waynesburg, Penn., 4600 acres of coal land in Monroe County. The deal involves $200,000.

Two men were injured, one probably fatally, when a 20-ton electric locomotive at the Wheeling Creek mine of the Lorain Coal & Dock Co. went down a 20-ft. embankment, near here, in the morning of May 17. The motor was buried in several feet of mud, one of the victims being pinioned under the frame.

East Liverpool—The Quaker Valley mines at Rogers have been sold to the Mullins Coal Co. and the mines which have been idle for some time will now be operated to capacity. The Mullins

company has other holdings at East Palestine, New Waterford and New Philadelphia.

Pennsylvania

Bituminous

Greensburg—The Loyalhanna Coal & Coke Co., operating mines in Derry Township, recently filed a suit against Michael Hines, James Quinn and Columbus Johnston for $150,000 damages. The plaintiff in its statement charges that the defendants own a tract of coal adjoining its tract of 1000 acres in the Pittsburg seam. During the last six years, the plaintiff alleges, the defendants have gone over their line and mined a large block of coal belonging to the plaintiff. Under the act of 1876 treble the value of the coal taken is asked.

Pittsburg—The Interstate Commerce Commission recently dismissed the complaint of the Association of Bituminous Coal Operators of the central Pennsylvania district against the Pennsylvania R.R. Co., holding that there exists no discrimination against the operators in the Clearfield district of Pennsylvania, and holding to be reasonable the existing rates on bituminous coal to South Amboy, N. J. The complainant alleged that the present rate of $1.55 per gross ton was unjustly discriminatory in favor of the Latrobe and Greensburg districts, which have a rate of $1.65. It was sought to have the rate reduced to $1.44.

Butler—Declaring that the new scale demanded by the miners cannot be paid without operating the mines at a loss, the Great Lakes Coal Co., of Pittsburg, owning four mines at Kaylor, has announced an indefinite suspension. Five hundred men are thrown out of work. The mines have been prepared for a shutdown for the past year.

Boswell—The Atlantic Coal Co., with operations near here, has recently acquired a tract of 1500 acres of coal land in Brothersvalley, Black and Summit townships. This adjoins another tract owned by the company, consisting of about 500 acres. These tracts are underlain with the B seam of coal which here runs from 6½ to 9 ft. in thickness. It is understood that the Atlantic company will commence operations here at an early date, building a plant of 1200 to 1500 tons daily capacity along a spur of the B. & O. R.R.

Connellsville—Connellsville coke production and shipments remain stationary at 400,000 tons and 12,000 cars weekly, chiefly because there is a persistent deficiency in the labor supply in spite of the fact that the region pays the best wages in the world. The furnace interests recently blew out 1530 ovens and fired 60, making a net decrease of 1470. Independent operators seem to be well supplied with orders.

The little Junction plant of the Marietta-Ganier Coke Co., at Broadford, idle since April, 1910, was fired up lately.

Anthracite

Scranton—One man was killed, two seriously and one slightly injured at midnight, May 16, when a slide of rock occurred near the Consolidated colliery of the Hillside Coal & Iron Co., in Moosic, where a 30-ft. cut was being made in fighting a mine fire.

The court recently handed down orders appointing mine inspectors' examiners and miners' examiners. W. L. Allen and Leon Whaite, mining engineers; and Patrick Flannelly, James Strong and John Bartosch, miners, were reappointed examiners of applicants for mine inspector.

The city council has passed a resolution authorizing the city solicitor to frame an ordinance whereby it is hoped that the streets of Scranton may be protected against damage by cave-ins. The resolution is now in the hands of the mayor.

The Bradley washery in South Scranton was destroyed by fire Saturday evening, May 18. The fire is supposed to have been caused by defective insulation of the electric wiring. The washery had not been in operation since Apr. 1. The loss will reach $25,000, of which amount about three-fifths was covered by insurance.

Wilkes-Barre—The tri-district convention of anthracite mine workers, which met here May 14, after a four days' session, voted on May 18 to accept the tentative wage scale agreement which was reached by the subcommittee of operators and miners on Apr. 25. The vote was 323 to 64 in favor of acceptance. There was at first much opposition offered to a ratification of these terms but President White and the more conservative element, in the end, easily dominated the convention. At a meeting in Philadelphia on May 20, representatives of the operators and miners signed the new agreement.

Mauch Chunk—The Anthracite Drifted Coal Co. has been organized by J. G. Reber and G. A. Alleman of Shoemakersville to recover the fine coal which has been washed down the Lehigh River and has collected above the dams at Parryville, Lehigh Gap and Three Mile Level, near Easton. Arrangements have been made with the Lehigh Coal & Navigation Co. permitting this work to be carried on.

Rhode Island

Providence—The mines and property of the Rhode Island Coal Co. at Portsmouth were sold at auction, May 17, by order of the U. S. District Court. All property of every kind owned by the corporation was sold excepting the mined coal in the yards at Newport. The real estate comprises a tract of 2446 acres and the whole property carries a mortgage of $100,000.

Washington

Chehalis—It is stated that P. C. Cockerill and other men of Sioux City, Iowa, whom he represents, will probably buy the coal mine at Littell which is owned by W. A. Conniff. Mr. Cockerill states that he has a market for all the coal that could be mined on the property.

West Virginia

Wheeling—Miners of the fifth Ohio subdistrict opened their convention here May 13 with 96 delegates present from 104 local unions representing 17,000 men. They appointed a scale committee, to report to the convention, and met the operators May 15. The Cleveland scale was used as a basis of settlement, but many questions relating to "deadwork," "sticky bottoms" and outside day work threatened to make trouble.

Bluefield—The Tierney Coal Co., which was recently incorporated in this state, is a holding company which owns some 11,000 acres of coal land in Pike County, Ky. This will be divided up and leased to operating companies. The property is underlaid by the Freeburn and Thacker seams and is located on the west side of Pond Creek. It will be served by the new line of the Norfolk & Western R.R., which is to be extended into that territory from Williamson and it is expected that construction work on this road will be started within the next few weeks.

Charleston—Despite the fact that one-half the mines in the Kanawha district were idle during the month of April, the coal output for that month passed all previous records, totaling 1,864,220 tons.

Fifteen hundred miners are on strike in the Paint Creek section.

Fairmont—Caving of the old Commercial mine on Coal Run recently caused a considerable subsidence of the surface and damaged property in the neighborhood. After an examination of the mine, further trouble was thought to be unlikely.

Canada

Regina, Sask.—Word was received from England, May 13, that J. H. Haslam had completed the formation of a $5,000,000 company with British capital for the exploitation of the Estavan coal fields. It is understood that Viscount Haldane and Winston Churchill have been named as directors of the new concern.

Ottawa, Ont.—William Ross, minister of mines and forests in British Columbia, recently interviewed Premier Borden in regard to the law compelling all railways in British Columbia to use oil for fuel after December 1914. Mr. Ross protested that this would be a great blow to the coal industry and urged that in an effort to protect the forests, the new provincial system of forestry patrol be given a trial rather than the compulsory use of oil.

Personals

F. E. Zerbey, general manager of the Kingston Coal Co., is recovering from an operation for a severe attack of appendicitis.

W. A. Ogg, comptroller of the Island Creek Coal Co., visited Duluth recently on business, and inspected the company's new dock, under construction at that point.

Harry E. Loomis, vice-president and general manager of the National Coal Co., of Cleveland, Ohio, recently sustained a fractured skull, as the result of a fall, while in Baltimore, Md.

H. J. Schmitt, assistant superintendent of the safety department of the Tennessee Coal, Iron & R.R. Co., has been made manager of a southern bureau of industrial safety, which he organized.

L. F. Card has been chosen superintendent of the Mine Foremen's Association, recently organized at Knoxville, Tenn. Kentucky, West Virginia, Virginia and Tennessee are represented in the organization.

Thomas R. Jones, formerly inside district superintendent, Lehigh division of the Lehigh Valley Coal Co., has been appointed inside superintendent of the Lehigh division and Coxe collieries, effective May 15.

Arthur Lewis, formerly district superintendent, Lehigh division of the Lehigh Valley Coal Co., has been appointed division engineer of the Lehigh division and Coxe collieries, with headquarters at Hazleton, Penn., as heretofore.

Benjamin W. Robinson, of Madisonville, Ky., a well known operator and formerly general manager of the St. Bernard Mining Co., suffered the loss of his home at Knot Lick, Mo., as the result of the tornado which passed that way recently.

Alexander Sharp, of Vancouver, B. C., mining engineer for P. Burns and associates, will shortly proceed to Alberta, to spend the summer in developing the Burns' coal mines, situated in the eastern foothills of the Rocky Mountains, southwest of Calgary.

Dr. J. J. Rutledge, of the Federal Bureau of Mines, has been spending a few days in Alabama, inspecting the mines and devoting considerable attention to investigating the working of gasoline locomotives, a number of which have recently been installed in Alabama.

George T. Robinson, superintendent of mines for the Cambria Steel Co., has tendered his resignation, to take effect at the end of the present month. He leaves to look after his personal interests in a number of coal companies and coal properties. Mr. Robinson has been with the Cambria company for the past 21 years, 11 years as superintendent of coal mines.

Construction News

Butler, Penn.—Thomas Lochrie has asked for bids on 12 new miners' houses at Argentine.

Dunlo, Penn.—The Mountain Coal Co. is installing an electric power plant at its local operation.

Wallins, Ky.—The Terry's Fork Coal Co. is installing electrical equipment and will operate its machinery with motor drives.

Milwaukee, Wis.—The C. Reiss Coal Co. is building a large new dock at Green Bay and will install coal-handling equipment and machinery.

Birmingham, Ala.—The Little Cahaba Coal Mining Co. will install an electric-power plant and equipment at its mines at Piper and Coleander.

The Sloss-Sheffield Steel & Iron Co. has placed orders for boilers and equipment aggregating $35,000.

Joliet, Ill.—The L. M. Rubens Coal & Transfer Co. will build a coal-storage yard of 5000 tons capacity, along the Chicago & Alton tracks.

Madisonville, Ky.—It is reported that Isaac and Bernard Bernheim will develop the coal property here, recently purchased from William Harris.

Durant, Okla.—A large central electric plant will be built at the coal mines 10 miles from here, to furnish power to Fort Worth, Dallas, Little Rock and vicinity.

Erie, Penn.—It is reported that plans are being made for the addition of another large coal-handling rig at the Susquehanna coal docks of the Pennsylvania R.R.

Clarksburg, W. Va.—The Maryland Coal Co. has awarded a contract for grading and laying tracks at its new mining property at Wendell, to C. P. Keeley & Co.

Mt. Sterling, Ky.—The Eastern Kentucky Land Co. has sent out inquiries for prices on equipment with a view to the development of coal land near Cumberland Gap, Tenn.

Brownsville, Penn.—Contract for a concrete lined slope and other construction work at the Lilley Coal & Coke Co.'s new mine has been awarded to the Drake-Stratton Co., of Pittsburg.

Ashland, Ky.—The Kentucky Solvay Coke Co., which was recently incorporated with a capital of $650,000, expects to spend $500,000 on the construction of its new coke ovens and byproduct plant at Ashland.

Warrior, Ala.—The American Coal Corporation, Belton Gilreath, president, is developing 10,000 acres of coal land for a daily output of 1500 to 2000 tons. It is reported that from $350,000 to $500,000 will be spent on improvements.

Louisville, Ky.—The Harlan Coal Mining Co. has awarded contracts as follows: Power plant and electric mining machine equipment, to the Morgan Gardner Co., Chicago; conveying machinery, to the Jeffrey Mfg. Co., Columbus, and boilers, to the Skinner Mfg. Co., Pittsburgh.

Barbourville, Ky.—The Harlan Coal Mining Co., recently incorporated, is perfecting arrangements for the development of 10,000 acres of coal lands. The land will be subdivided and leased. It is reported that eight or ten separate mining plants will be installed this summer. These will be electrically equipped.

Publications Received

INVESTIGATIONS OF EXPLOSIVES USED IN COAL MINES. By Clarence Hall, W. O. Snelling and S. P. Howell. Bulletin No. 15, U. S. Bureau of Mines. 196 pages, 6x9 in., illustrated.

The bulletin describes the method used in testing explosives, and defines what a permissible explosive is. On this subject, W. O. Snelling says: "The underlying causes for one explosive being safer than another in the presence of explosive mixtures of gas or coal dust have been investigated during the past few years. The many thousands of lives lost in coal-mine disasters have shown the necessity of such investigations, and have stimulated to a marked extent researches in regard to the preparation of explosives suitable for use in coal mining. It has been found that every known explosive, if fired in a sufficiently large charge, will cause the ignition of an explosive gas mixture, but explosives have been found to differ widely in regard to the amount that can be fired without causing such ignition. Ordinary black blasting powder, for example, will cause the ignition of explosive gas mixtures very readily, as little as 25 grams invariably serving to bring about this result. Certain other explosives, in quantities as great as 1000 grams, after repeated trials, under conditions exactly similar to those used in testing black powder, have invariably failed to cause ignition of the explosive gas mixtures."

Trade Catalogs

National Foundry & Machine Co., Louisville, Ky. Catalog No. 12. Reilly Steam Pumps and Air Compressors. 160 pp., 5¼x7¾ in., illus.

Shear-Klean Grate Co., Chicago, Ill. Booklet "Save Coal," descriptive of a new shaking grate, recently placed on the market. 12 pp., 4x9¼ in., illus.

The Goulds Manufacturing Co., Seneca Falls, N. Y. Bulletin No. 112. "Handy Data on Power Pumping." 16 pp., 7¾x10 in., illus. Contains a compilation of the data required for figuring on the usual pumping installations for various purposes with special reference to belt or gear driven pumps.

Industrial

The executive offices and New York show rooms of the H. W. Johns-Manville Co., manufacturers of asbestos, magnesia and electrical supplies, were moved Apr. 20, to the new 12-story H. W. Johns-Manville Building, Madison Ave. and Forty-first St., New York City, from their old quarters at 100 William St., where they have been located for the past 15 years.

Increased business interests in this and other parts of the country have necessitated the move. The large floor area and spacious rooms in the new building, will enable a much larger and more complete stock of goods being carried on hand than heretofore, and will also permit of a better supervision over the company's long chain of branch offices, warehouses, stores and factories scattered throughout the United States and Canada.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

The conclusion of the anthracite strike is viewed with general satisfaction in trade circles. Even though prices ease off and the market settles down into the customary summer dullness, all uncertainty has, at any rate, been removed and normal conditions will soon prevail again. Anthracite dealers will try to lay in as much low-priced summer coal as possible, and the season's trade promises to be very active.

The consumers are impatiently waiting the announcement of the new anthracite circular, and it seems there may be some trouble in fixing a satisfactory scale of prices. The steam quotations cannot be increased because of the competition with bituminous, while an advance in egg would tend to shift the demand for this grade to stove and chestnut. This apparently only leaves three sizes, representing less than half the anthracite production, upon which the increased cost of mining can be made up.

The present outlook in bituminous is not encouraging. There has been an almost continuous heavy production since the first of the year, and with all hopes of profiting by the anthracite suspension now gone, only a rigid curtailment at the mines can prevent a repetition of last season's low prices. The Eastern movement is confined almost entirely to contracts, and prices are easy, with very little new business being done.

The demand at Pittsburgh is light, with the mines working about 50 per cent. capacity, chiefly on Lake orders. In Ohio the trade is proving a decided disappointment, although there is as yet no attempt to force the market by price-cutting. There is very little of the customary early summer stocking of domestic, but a fairly strong demand for screenings is in evidence.

In the South the market is in a very satisfactory condition, due to a renewed activity at the blast furnaces, which has taken this grade of coal out of the commercial market. Larger tonnages are moving in the West, and the demand is slightly improved.

Boston, Mass.

Some of the bituminous shippers are freely predicting a repetition of last year, and the feeble hopes built on the anthracite-strike prospects have now vanished. Only a rigid curtailment and strong control on the part of operators can prevent another season of small returns. The months January to May saw a heavy movement, particularly from the West Virginia districts, and it will be hard to put production back to an off-year basis. The export market, from which much was expected, is also falling off for the present. The trade in general is beginning to realize that stocks are large and that without special inducements the demand will be light for months to come.

The all-rail trade is gradually recovering from the effects of the March "flurry," and will soon be on the usual basis. For summer months certain of the mines are offering at last year's contract prices, but buying is only from hand to mouth.

Georges Creek shipments have been heavier than usual. These shippers were the first to announce contract prices and have reaped benefit also from the anthracite barges they were in position to use. An increasing differential between their price and that on Pocahontas and New River will tend to offset the advantage they have enjoyed so far this season.

The settlement in anthracite will be welcomed in New England. With the suspense over, dealers will now plan spring shipments and get forward as much of this low-priced coal as they can store. A strong demand and a slow shipping season are looked for through the summer, and dealers are anxious to hear what the opening prices will be. There have been rumors that one of the anthracite companies that has always been prominent in the tidewater trade is to withdraw, in order to concentrate along the line and in the West.

Current wholesale prices are about as follows:

Clearfields, f.o.b. mine	$1.10@1.35
Clearfields, f.o.b. Philadelphia	2.35@2.60
Georges Creek, f.o.b. Baltimore	2.70@2.80
Pocahontas, New River, f.o.b. Hampton Roads	2.70 or less
Pocahontas, New River, f.o.b. cars Boston	3.60@3.70
Pocahontas, New River, f.o.b. cars Providence	3.45@3.50

New York

Anthracite—The final agreement between the anthracite miners and operators has caused a decided flurry in the hard-coal market here. Preparations are being made to handle heavy tonnages when the mines get under full operation again, and consumers are anxiously awaiting the announcement of the new circular. The large operating companies are now fixing the new scale, which will doubtless show an appreciable increase over the one now in effect.

The hard-coal trade is in a strong position, and the season's shipments will probably see some new records established here. Supplies are down to an unusually low point, and there is considerable doubt expressed as to the ability of the mines to catch up before fall.

Pending the announcement of the new schedule we continue to quote prevailing prices at the old circular as follows:

Broken	$4.50
Egg and stove	5.00
Chestnut	5.25
Pea	3.25
Buckwheat	2.75
Rice	2.25
Barley	1.75

Bituminous—The bituminous market has settled down into the usual summer dullness, and it is thought the next two months will see a relapse in this trade. The large wholesalers, however, maintain optimistic views for the future, and believe that conditions are about normal for this period. Bituminous has undoubtedly been sustained to some extent by the uncertainty in the hard-coal situation, and with this feature eliminated the market will probably weaken.

Spot bituminous prices, f.o.b. New York, are about as follows:

West Virginia steam	$2.35
Ordinary grades Pennsylvania	2.45
Fair grades, Pennsylvania	2.55@2.65
Good grades, Pennsylvania	2.70@2.80
Best Miller, Pennsylvania	3.00
Georges Creek, West Virginia	3.15

Pittsburgh, Penn.

Bituminous—Demand for coal continues slack in the local market. Mines are now running at better than 50 per cent. of capacity, but chiefly on Lake coal, the movement in which has now assumed fair proportions. The expectation continues that this will prove to be the banner year in Lake shipments. Prices in the local market have not been well tested, and the quotations announced at the opening of the mines may still be quoted as nominally the market: Mine-run, $1.22½; ¾-in., $1.32½; 1¼-in., $1.47½; slack, 82½c., per ton at mine, Pittsburgh district.

Connellsville Coke—Contracting for furnace coke for the second half of the year has definitely begun, two contracts being announced in the past few days, one 10,000 tons monthly at $2.35 and one for 6000 tons monthly at $2.40. Several weeks ago, a contract for 10,000 tons monthly was made at $2.35. Many of the operators have set $2.50 as their objective point, but furnaces will not pay

this price without a struggle. The merchant furnaces, as a rule, cannot afford to do so, on account of the low price of pig iron.

The prompt market has eased off in the past two or three days, and prompt furnace coke can now be secured without difficulty at $2.25, against $2.40 freely paid a week ago. The $2.25 price has even been shaded today. We now quote: Prompt furnace, $2.25; contract furnace, $2.35@2.40; prompt foundry, $2.75; contract foundry, $2.75.

The *Courier* reports production in the Connellsville and lower Connellsville region, in the week ending May 11, at 401,960 tons, an increase of 116 tons, and shipments at 4331 cars to Pittsburgh, 6339 cars to points west and 1321 cars to points east, a total of 11,911 cars, an increase of 62 cars.

Philadelphia, Penn.

The long, expensive suspension in anthracite is now at an end, and probably the public will be asked to pay the bill. Much speculation is rife as to what the probable prices will be. With a market practicaly bare of coal, there will probably be no concession in prices made, the operators depending upon this fact to dispose of their output. If the latter arrangement is followed out, and the trade remains indifferent, the coal, in all probability, will be placed in stock, to provide for the tremendous demand that will come in the fall. It is almost a foregone conclusion that there will be an advance in the prices of some of the sizes —probably stove and pea—if not now, then later on in the fall. When it is remembered that the steam prices have to remain at their present level, in order to meet the competition of the bituminous coals, and cannot, therefore, be burdened with any of the increased cost of mining, and that any advance in the price of egg is likely to shift the demand for this size to stove and chestnut, it leaves little to bear the burden of the increased cost of production but the three intervening sizes, representing only 40 to 45 per cent. of the output.

Reports from the mines indicate that it will be a month before the collieries will be operating on anything like a normal basis. The opportunity afforded by the suspension led many of the foreign element to take advantage of the idleness for a trip to their homes in other countries, while others have gone to the bituminous fields. Most of the latter will soon return to the anthracite mines, and the former, as soon as they are aware that peace is assured.

The bituminous trade seemed to have profited little by the suspension in the anthracite region. One operator said that he had not had such a dull period for many years, and might be compelled to close down his plant. Many bituminous operators have been turning down contracts, in the hope of reaching more benefits through a continued strike in the anthracite, but the prices of 1902 saw no duplication in the 1912 difficulty.

Baltimore, Md.

While coal moved with regularity at all of the railroad piers in Baltimore throughout the week, there was a hesitancy on the part of shippers to forward their product through this port for fear there might be a renewal of the strike. Consequently, the local market was not very active, especially so far as spot business was concerned. Consumers desiring immediate deliveries were as timid as the operators, and took no chances of having it held up at this port.

Practically all of the shipments handled at the piers here during the week were moving under contract, and, to the credit of the railroads, operators have not had much to complain about in the movement. The stevedore strike is still in progress, and many laborers are being intimidated, but the railroads have done everything possible to get their full quota of men at the piers, and they have succeeded in doing quite well; they have their full complement of men at work, and expect no further trouble.

Inquiries at the offices of the local operators shows that very little new business is being booked at this time. Prices are easy, and it was stated by one operator that the low grades could be purchased for 65@70c. per ton, with the next best at $1@1.10 per ton. The big vein Georges Creek coal is now bringing between $1.60 and $1.70 per ton.

The coke market is gradually improving. Inquiries are increasing, and some business is being closed; the improvement in the steel trade is responsible for this.

Buffalo, N. Y.

There is not much activity in the bituminous market yet, but here and there a consumer is running short, and the demand will increase slowly from this time on. Prices are not strong, though it is claimed they are firmer than in the East, especially in New England. This section suffers from an excess of production, but not to the extent the West Virginia markets do.

There is practically no anthracite moving, though if anyone is in great need of a little it can generally be obtained. There has been no complaint from the consumers in that trade and would hardly be any till it is time to stock up in September. There is all manner of speculation as to the price that will be asked when the supply returns, the general belief being that higher prices will be asked.

Some members of the bituminous trade claim to be getting full prices, and say that the very low quotations reported are for inferior grades or small amounts that are in danger of incurring car service. Prices are not very strong, however, at the following regular figures: Pittsburg three-quarter, $2.57½; mine-run, $2.47½; slack, $2.25. Coke is not strong, but is fairly active at $4.50 for best Connellsville foundry. Stock coke is stronger than the higher grades.

There is a fair amount of contracting for bituminous, some believing that the usual tonnage is already placed, though at the beginning of the season neither buyer nor seller was anxious to contract. There is not much difference in price, either for immediate consumption or on contract, from last year, so that the bituminous trade is not getting on its feet very rapidly yet. Profits will continue to be small.

There is no coal traffic from here by Lake yet, and it will be some time after the mines are active before there will be much anthracite for shipment. Much effort will be made to catch up with last season when the start is made, but it is doubtful if it can be done, as the Eastern demand will be heavy.

Cleveland, Ohio

Very little improvement, if any, has taken place during the past week in this market, owing to the general dullness in the trade and the large amount of coal that manufacturers stored prior to the suspension. A great deal of this coal is still on hand and manufacturers are loath to stock up further until they see prospects of a business revival and this is making the trade slow.

A number of mines have started up in the past two weeks, due principally to the opening of the Lake trade. It is reported by some operators that difficulty is experienced in procuring sufficient men to work in the mines.

The greatest demand is for the fine sizes. There seems to be quite a shortage of that grade, owing to the mines not running full. Prices are: No. 8, $1.55@1.60; No. 6, $1.45@1.50; Pittsburg gas slack, $1.55@1.60. A small quantity of coarse coal came to this market during the past week, and there has been great difficulty in disposing of it at a fair price.

The increased cost of mining makes this situation rather discouraging to the operator. However, this condition is looked upon as only temporary, as when Lake shipments start, which will be about June 1, the demand will resume its normal activity.

Very few contracts have yet been made, which is contrary to the usual custom in the past. Manufacturers prefer taking chances in the open market. Many domestic dealers are also holding off this year, a condition which has never existed in the past.

Columbus, Ohio

The May coal trade is proving a disappointment in all branches, with the exception of the Lake movement. It is found that both steam consumers and retail dealers are stocked far beyond normal for this period of the year. In the case of the steam trade, heavy tonnages were taken on in March, sufficient to run plants, in many instances for several months to come. This is particularly true of the mine-run grade.

The fine-coal market is being stimulated by idleness at mines in Indiana, where district conditions have not yet been settled. This has caused an advance in price of 10c. a ton on nut, pea and slack, and jobbers are readily buying up every car of these grades available.

It is in the early domestic stocking trade that the dullness is most marked, as May usually sees these grades sold up well into the summer. The present condition is explained by the fact that a very large tonnage of high-priced coal was shipped from the mines during the extreme cold weather in the early part of the year. As a result, dealers are now lacking yard room for stocking splint, smokeless and other grades, which they usually put in early.

Slow delivery has been hard on shippers, as bills are not usually paid under 30 days from time cars arrive at destination. Many operators are giving more thought to their collections than to new business. No attempt appears to be made at forcing the market by price cutting, and there is hope of a prosperous domestic business later in the summer.

Birmingham, Ala.

The coal market of Alabama retains its strength and is tiding over the dullest part of the year in very satisfactory manner. Dealers have been prosecuting a vigorous campaign for business and have to their credit, orders which heretofore have not come to the Birmingham district. The contracting for steam coal is opening with very satisfactory outlook and June and July will witness several important orders rounded into contracts at good figures.

Just now iron is buoyant and promising. Furnace companies are not actively seeking markets for their surplus coal, as was the case a few months ago. All of the iron companies are figuring on increasing their furnace capacity and the indications are that they will prefer to store coal rather than push it into the open market as a labor shortage seems probable in the coal fields.

It also seems certain that more commercial coal will be mined this year than any previous year if the present rate keeps up. The output is being taken care of in new markets west of the Mississippi River, by increased bunkerage at New Orleans, Mobile and Pensacola, by railroads not hitherto using Alabama coal and by making some gain in the fiercely competitive fields of Georgia.

Commercial coke producers report an active market with abundance of orders at favorable prices. The situation at the more northern furnaces has tended to assist in keeping Alabama coke firm at present prices. In the coke market as in the coal, the furnace requirements ease competition in the open market and the year promises to show a gradual improvement on this account.

Indianapolis

There is little or no change in the situation in this state. Both operators and miners are greatly disappointed because mining has not been resumed, and much interest is manifested in the action of the joint conference now in session at Terre Haute.

Orders are piling up with the operators which they are unable to fill. It is not pleasing or encouraging for them to see their customers going to other fields to obtain coal. The Lake trade continues to order Indiana coal, but without avail. Domestic consumers and manufacturers have borrowed coal, much of it from the railroads, to keep their plants going, but even this source is beginning to show such a diminution as to look decidedly ominous.

Those who prophesied that the Indiana mines would resume operation more than a week ago are again as confident that they will be at work before the close of another week. The weekly pay remains the only difference in the way. The operators declare that a weekly pay will increase the cost of construction in violation of the Cleveland agreement, and the miners' officers admit that it is up to the miners to prove that it will not.

St. Louis, Mo.

There is a slightly larger tonnage coming into the St. Louis market, and the demand has increased some over last week. However, the incoming tonnage has exceeded the demand, and this has resulted in a cutting of prices.

The contract for the schools of St. Louis went to the Devoy & Kuhn Coal & Coke Co., at $1.82 delivered for screened lump coal from the Belleville or Standard district. The other city contract, calling for 4000 tons of No. 4 washed coal, went to the Southern Coal & Mining Co. at $1.90 delivered. The rate on this coal is 52c. as well as on Donk Bros., who were the next lowest at $1.92 delivered.

There are a few other contracts of a like nature that are still hanging fire, but it is hard to prophesy as to what they will go at. On Carterville district coal contracts have been let as low as $1.05 at the mine on mine-run, 75c. on screenings, $1.25 on nut and $1.35 on everything above two inches. It is understood that the railroad mine-run contracts this year will be in the neighborhood of $1.12.

There is very little demand for coke, and practically nothing doing in the smokeless line right now.

The market opened the early part of the week as follows:

Williamson and Franklin County	
6-in. lump	$1.30@1.40
3x6 egg	1.30@1.40
2x3 nut	1.25@1.35
2-in. screenings	1.05@1.15
Mine-run	1.05@1.15
Mount Olive	
3-in. lump	$1.25
Nut	1.25
Screenings	1.10@1.15
Mine-run	1.10@1.15
Standard	
6-in. lump	$1.00@1.05
2-in. lump	0.95@1.00
2-in. screenings	0.95@1.00
Mine-run	0.90@0.90

Chicago

Within the last week a slight improvement has been noted in the Illinois coal market. Small orders have appeared here and there for domestic lump.

A resumption of cold weather has caused a steady consumption of coal which has led to a small amount of buying from the retailers. Springfield lump continues at $1.50 and steam lump remains firm at $1.25. Southern Illinois steam coals are a little higher, as a result of a boost in freight rates. Reports indicate that mines in the Hocking Valley district are running at about full time; a small part of this coal is reaching Chicago. The Chicago price has not been changed, being $1.50 at the mines, or $3.15 f.o.b. Chicago.

There are some inquiries for coke contracts. Spot business is fairly good and prices are steady to firm.

Prevailing prices at Chicago are:

Sullivan County	
Domestic lump	$2.37
Egg	2.12
Steam lump	2.02
Screenings	2.02
Springfield	
Domestic lump	$2.32
Steam lump	2.07
Mine-run	1.97
Screenings	1.97
Clinton	
Domestic lump	$2.27
Steam lump	2.02
Mine-run	1.92
Screenings	1.92
Pocahontas and New River	
Mine-run	$3.15
Lump and egg	3.30@3.55

Coke—Prices asked for coke are: Connellsville and Wise County, $4.75; byproduct, egg and stove, $4.55; byproduct, nut, $4.55; gas-house, $4.75.

Portland, Ore.

Portland and all of Oregon are already in the midst of warm summer weather and there is little business for the coal man these days. Storage rates have not yet been announced but if the warm weather continues, the dollar will soon

be lopped off quotations to those who are willing to stock up when business is dull. There is considerable agitation here to have the railroads extend lines into the coal fields of eastern Oregon so that these can be developed.

San Francisco, Calif.

The importations by sea for the month of April were: 10,343 tons of Wellington; 4971 tons of Australian; 16,683 tons of Pocahontas and 4840 tons of steam coal from the state of Washington. Deliveries by rail were normal. Climatic conditions have not stimulated demand for household purposes and movement of coal has been far from brisk.

Owing to the small arrivals of Australian during the past three months, the total aggregating only 9636 tons, the stock of this grade has been considerably lowered; probably today there is not more than 10,000 tons on hand.

Prices remain unchanged, the rate to dealers being as follows per ton:

Wellington (British Columbia)	$8.00
Pelan Main (Australian)	8.00
Rocky Mountain	8.50
Anthracite (Pennsylvania)	15.00
Cumberland	12.50

Production and Transportation Statistics

The Girard Estate

Anthracite coal-mining operations on the property of the Girard Estate in 1911 were conducted on the largest scale on record. Both the production and shipments of coal, from the estate exceeded those of any previous year. Total production was 2,420,747 tons and total shipments 2,162,047 tons. As compared with these figures, the total production in 1907, the heaviest previous year, was 2,306,143 tons and the total shipments 2,101,199 tons.

The Consolidation Coal Co.

The Consolidation Coal Co. is now shipping coal at the rate of 40,000 tons per day. The business of the Consolidation has been heavy since the first of January. The shipments reported for the period from that date to May 9 totaled 3,587,257 tons as compared with 2,832,443 tons for 1911, or a gain of 754,814 tons for the current year.

The Car Situation

The idle car statement of the American Railway Association for the two weeks ended on May 9 shows a decrease in the net surplus of 8783. The total surplus over and above the shortages reported in some sections was 130,008.

This decrease, following a sudden and large increase in the number reported in the preceding statement, is explained by the resumption of activity in the coal fields and the release of stored up fuel in view of the settlement. In the two weeks just reported for, the surplus of idle cars decreased from 94,943 to $3,512. That general business has not improved correspondingly is indicated by an increase in the box-car surplus from 19,583 to 20,626.

The following table shows the surplus and shortages of cars on 167 roads on May 9 last:

	Surplus	Short	Net Surplus
Box	20,626	3,294	17,332
Flat	3,261	1,454	1,807
Coal, gond. and hopper	83,512	1,233	82,279
Other kinds	29,377	697	28,680
Total	133,776	6,678	130,098

Anaconda Copper Mining Co.

The coal department of this company produced during 1911, 800,073 tons, as compared with 828,529 tons for the year previous. Company is making extensive hydro-electric installations, by which they are effecting considerable economy in their coal consumption. The Belt mine, representing about one-eighth of their total production, is scheduled to be closed June 30.

The Island Creek Coal Co.

This company has produced during the first four months of the current year about 625,000 tons of coal, or at the rate of 1,900,000 tons for the whole year. Production during April exceeded 180,000 tons, and for May should reach about 200,000.

Foreign Markets

Germany

The following is a statement of the production, imports and exports in the German Empire, for the month of March, 1912, in metric tons:

	Production	Imports	Exports
Coal	12,811,823	497,457	2,420,993
Lignite	7,041,990	709,083	4,445
Coke	2,130,905	40,599	507,748
Briquettes	2,009,240	17,005	240,605

Great Britain

Business in all branches of the steam-coal trade continues very quiet; colliery outputs remain abnormal, with the result that supplies are very plentiful and prices show a further heavy reduction:

Best Welsh steam coal	$4.68
Seconds	4.50
Thirds	4.14
Best dry coals	4.62
Best Monmouthshire	4.32
Seconds	4.14
Best Cardiff small coal	2.52
Seconds	2.40

The prices for Cardiff coals are f.o.b. Cardiff, Penarth, or Barry, while those of Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days, less 2½ per cent.

British Exports in 1911

The total coal exports from Cardiff were 16,127,777 tons. The northwestern ports exported 711,703 tons, and the northeastern ports, 21,716,027 (New Castle 6,884,611 and South Shields 5,299,752). Humber ports exported 6,264,063 tons, and other English ports 325,376. Scotland exported 10,382,311 tons and London only 2089.

Nearly half the coal exported by Great Britain brings prices ranging between $1.92 and $2.66 per ton. Of the grand total, the Bristol Channel ports exported about 40 per cent., but these ports are responsible for practically the whole of the coal exported at prices exceeding $3.12, the figures being 19,221,076 tons out of a total of 19,727,291.

Financial Notes

The International Coal & Coke Co., capitalized at $3,000,000, paid $56,073.38 in dividends, expended $77,554.28 for maintenance and $47,029.61 for improvements and equipment at its plant during 1911.

The Island Creek Coal Co. will this year expend $500,000 for the erection of a huge dock at Grassy Point, Duluth, capable of handling 400,000 tons of coal and storing 200,000 tons. This development is to be paid for with surplus cash funds already in hand.

In the first quarter of 1911 operations of the Pittsburgh Coal Co. resulted in a considerable deficit, whereas this year the net earnings for the first three months showed a substantial surplus. An increase in the preferred dividend from 5% is in prospect.

That the Lehigh Coal & Navigation Co., which owns no railroad, is making money on mining coal, is shown by the payment of 8% dividends and by the increase of capital stock from 19,000,000 to 26,500,000; by a scrip dividend of 15% in 1910 convertible into stock and a 10% allotment of stocks at par in 1911.

The Reading Co. owns directly, through the Philadelphia & Reading Coal & Iron Co., over 40% of the anthracite deposits of Pennsylvania, and indirectly, through the Jersey Central, which holds 97% control of Lehigh & Wilkes-Barre Coal Co., 17% more. The Reading Coal & Iron Co. produces roughly 10,000,000 tons and the Lehigh and Wilkes-Barre 5,500,000 tons of anthracite per annum out of the total of 65,000,000.

Chairman Taylor, of the Pittsburgh Coal Co., states that the pension-fund plan becomes effective Apr. 1 next. The pension fund on Dec. 31 amounted to $92,329. The year's receipts of the relief fund, including a balance of $45,755 on Jan. 1, 1911, were $161,842, the company appropriating $32,129. After the 1911 disbursements had been made there remained a balance of $42,886. Since the fund was established, receipts have amounted to $1,068,386, and disbursements to $1,025,500.

In the five years 1907 to 1911, inclusive, the Philadelphia & Reading Coal & Iron Co. paid out for rail transportation a total of $40,283,313. Undoubtedly the major part of it went to the Reading Ry., but not all. Granting that it did, however, and assuming that the railway's expense ratio on moving the hard coal from the Coal & Iron Co.'s collieries is 50% (ratio of all expenses in 1911 was 60.6%) the railway saved for its net $20,141,000 on coal carried for the controlled property during these five years. Deducting from this railway net the $9,900,000 said to have been lost on the operation of the collieries, a little over $10,200,000 is left to represent the profit of Reading coal mines to it

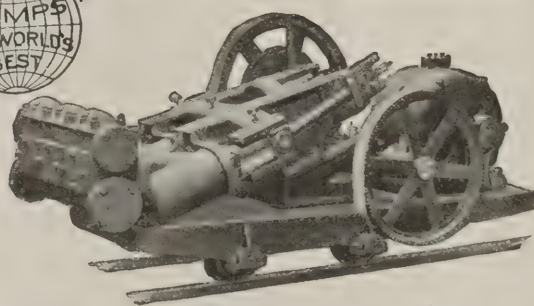
DEMING PUMPS THE WORLD'S BEST



In Your Coal Mine Deming Pumps

can prove as serviceable as in the mine of a coal company in Virginia (name on request) where one pump handled gritty and dirty water for two years continuously without one cent spent for repair parts.

The Deming Pump shown above being electric driven and portable, can be taken any place your tracks go and is extremely valuable for emergency use.

Baldwin-Westinghouse Mine Locomotive

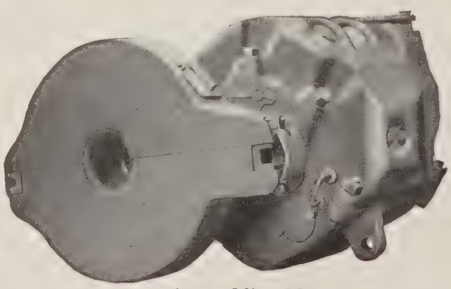
Apparatus that will give thoroughly satisfactory service is produced by long practical experience.

Baldwin-Westinghouse Electric Mine Locomotives

are the products of the combined experience of the Baldwin Locomotive Works, for 80 years the foremost locomotive builders in America, and the Westinghouse Electric & Mfg. Company, the leader in the manufacture of electric haulage equipment ever since the beginning of electric traction.

This experience is embodied in the design of every detail in the construction of Baldwin-Westinghouse mine locomotives. Each part is known to be best adapted to the service it must perform.

In consequence, Baldwin-Westinghouse mine locomotives are, above all, reliable.



Westinghouse Mine Motor

They do their work steadily day in and day out, getting out maximum tonnage at the least expense and in the shortest time.

There is a Baldwin-Westinghouse locomotive for every class of service. The proper locomotive for your mine will be recommended by Westinghouse engineers after a careful study of conditions.

Address either Company—

COAL AGE

Vol. 1 NEW YORK, JUNE 1, 1912 No. 34

CONSERVATION as indicated by high percentage extraction of our coal areas is a question of great moment, but elimination of the larger wastes of human effort is even more important. Losses of material things are visible; a lack in operating efficiency is less tangible. The former stirs us deeply; the latter is but vaguely appreciated.

At no time in history has the demand for competent men been so far in excess of the supply. Too many are looking for the ready-made man, and too few are willing to secu e competent help by themselves training employees. The idea that "Captains of industry are born, not made ' is too broad; men must be trained right, as well as born right. No great man can compete wi h a number of ordinary men efficiently organized.

In the future, *system* will come before the *man*. Under efficient management, the superior man rises more surely and more rapidly than ever before. The correct synonym of *conservation* is *national efficiency*, and the latter can be brought about by the general adoption of systematic management, rather than by the discovery of extraordinary men.

Good management is an exact science, based upon definite laws. Fundamental principles are applicable to all activities, whether individual or corporate. Any scheme where the organization of employers, as well as employees, is for war rather than peace, is poorly devised. The chief aim of every plan should be to secure maximum prosperity for both employer and employee.

If an operator and miner working together become so skillful that they can mine two tons of coal while a competitor and his workman mine only one ton, it is certain that the first operator can pay higher wages, and still have a larger profit than his competitor. In other words, maximum prosperity can only exist as the result of maximum productivity.

When engaged in a game of sport, the employee strains every nerve and muscle to win. If he failed to do so, he would be branded as a "quitter." But in the routine of his daily work, the same man plans to do as little as he can. If he acted otherwise, his fellow-workers would condemn and threaten him. In the labor world it is thought honorable to "soldier," and that belief is the most dangerous disease that has afflicted society today. Nothing would do more toward promoting prosperity and eliminating poverty than doing away with the ancient and respectable habit of "killing time."

The fallacious reasoning that causes workmen to approve "soldiering" is based on the belief that "a material increase in the output of each man or each machine results finally in throwing a number of men out of work." It is also true that the evil habit has been fostered by defective systems of management, which include a total ignorance on the part of employers as to the proper time in which work of various kinds should be done.

The tendency to "take it easy" is encouraged also by "rule-of-thumb" methods, which should be replaced by scientific schemes, based on a careful study and elimination of unnecessary motions, and the substitution of fast for slow methods of working. There are at least a dozen ways of doing each act in mining coal, and for the same reason there is a variety of implements used for each class of work.

There is always one method and one implement which is better and faster than any of the rest, and it is in the discovery, selection and development of these higher efficiency methods and tools that the value of scientific management rests. All old systems make it imperative that each man shall do his work as he thinks best, without help or advice from the management. This plan makes it impossible for employees to work in accordance with scientific rules, even where such laws exist. It is just as essential to know how to manage men efficiently, as it is to handle problems in ventilation, pumping or haulage.

The Lanchow Mines in China

By K. P. Swensen*

The Lanchow Company is purely a Chinese institution, but under the technical management of three German engineers. These men, following the dictates of their training, have built up a plant of wonderful permanency. Among the many problems encountered, one of the most serious was the difficulty in overcoming the oriental prejudices and customs.

The best known and most extensively worked coal field in China, is that district in the northeast part of the country. This area extends west from the Gulf of Pechihli to the vicinity of Peking and the western boundary may be said to follow southward approximately in the direction of the south branch of the Great Wall, traversing the border line between the provinces of Chi-Li and Shan-Si and southward into Ho-Nan. Nothing but the merest conjecture can give one an idea of the vast quantity of coal lying in reserve in this area, from which, at the present rate of consumption, there is probably a supply sufficient to provide the world's needs for several centuries.

Of the many districts in the field, the most important and oldest is that of the Kaiping district, situated along the line of the Imperial Railways of North China 60 miles north of Tientsin. The principal operator in this district is the Chinese Engineering and Mining Co. which has its largest plant in Tongshan. It is interesting to note that the history of this company from the date of its beginning in 1879 up to the present time, correlative as it is with the modern industrial progress in China, is typical of the manner in which the whole of China has slowly and hesitatingly accepted the Western innovations in industry, government and commerce during the process of her awakening.

General View of the Lanchow Mining Co.'s Surface Plant, Showing Auxiliary Hoist to the Left

Prejudices of the Orient

Enterprises in China, whether the result of foreign or Chinese initiative, have always had the wall of native prejudice and ignorance to contend with. This feeling exists, to a certain extent, to this day, as may be noted in the extreme difficulty that foreigners or progressive Chinese have in obtaining concessions favorable to modern mining development, or in any of the industrial enterprises in which foreign control is concerned. The attitude of the Government, however, is very strongly in favor of native enterprises at all times and gives every encouragement it can to such ventures. Lack of capital, or unwillingness on the part of the Chinese to invest in new and unfamiliar undertakings, continues to be the reason of the present undevelopment of her vast mineral resources.

When we consider the extremely low cost at which the Chinese are able to mine coal with their cheap labor and modern machinery, there is every reason to believe that in a comparatively short time, they will find a market on the Pacific Coast region of America, notwithstanding the coming completion of the Panama Canal, unless the Alaska coal fields become heavy producers. Lack of shipping ports with good harbors, and of railway and steamship transportation facilities are at present the drawbacks to the Chinese in realizing this ambition.

There is a need for a world market for Chinese coal, as there now seems to be an oversupply in the Orient of all coals except the navy lump. Local needs are therefore easily supplied by the production of the present plants in operation. In the Kaiping district a fair grade of bituminous coal sold at the mine at as low a price as $1.10 per ton during the summer of 1911, when competition among the different companies was keen. This allows for a very meager profit or none at all on a heavy investment even though coal may be mined in China at a figure that is easily one-half of what must be paid in the United States.

Shipping Conditions

A Chinese coal mining company of Kaiping district, known as the Lanchow Mining Co., has recently started to produce coal and coke in competition with the Chinese Engineering and Mining Co. The company's property lies between the Tongshan and Linsi mines and the workable coal seams extend for a distance of about 15 miles. The parent shaft of the mines is at Machiakow, which is three miles from the railway station at Kaiping. A standard gauge railroad, operated by the company, is used for hauling the company's product to Kaiping, from which point it is shipped to the port of Tongku and also to Tientsin.

The shipping port of Tongku is ice

*Mining engineer, Nanking, China.

bound in winter, which prevents the company from shipping its product to points outside of its own local territory for at least four months of the year. Furthermore, the harbor is not deep enough to accomodate the deep sea going vessels. This places this company at a disadvantage with its competitor, the Chinese Engineering and Mining Co., who have their own private shipping port at Chin Wang Tao, which is free from ice all the year around, and from which coal may be loaded on to vessels of deep draught.

The Lanchow Mining Co. is purely a Chinese organization, started in 1909, and in which Chinese capital only is concerned; of the operating staff, there are only three foreigners in the employ of the company. These are the three German engineers, who constitute the technical management. It is the desire of the Chinese to employ only such foreign help as is absolutely necessary in the carrying on of this enterprise. In common with the practice of some of the other Chinese mining concerns, the Lanchow company has started up a mining school in conjunction with the works for the purpose of training its own engineers and officials who will eventually occupy the various positions in the management of the company. The company is at present capitalized at 4,500,000 taels,* about 3,000,000 taels having already been expended for the present surface equipment and underground development.

The Geology

The coal beds which are now being worked by the Lanchow Mining Co., occur in a limestone belt of Carboniferous formation which has been tilted and faulted, this latter being revealed in the stratification of the nearby hills which rise abruptly out of a vast area of alluvium and loess. This condition has made it necessary for the company to do its prospecting, in the tracing of outcrops, by sinking test pits. Indications of the location of the main seams were discovered from examination of the old native pit workings.

*The Chinese tael is equal to an ounce of silver, or about 70c. gold at the prevailing market price of silver.

Opposite View of the Surface Plant, Showing Trestle for Conveying Coal to the Boiler Plant

The coal-bearing formation, consisting of shales and sandstones and a variety of shaley clays, appears to be along the north fold of a syncline, which has been described by Drake.*

Beginning at Tongshan where the inclination is steepest, it follows in an easterly direction for a distance of 21 miles until Linsi is reached. At Linsi, the location of one of the Chinese Engineering Co.'s mines, the dip of the seams is only 10 deg. At Tongshan, the western extremity of the syncline, the formations have been greatly disturbed by upheavals. At the Lanchow workings, however, the seams thus far encountered are quite regular and undisturbed. There are no serious dislocations by faults and the earth pressure is not great. At Ma Chia Kow the dip of the seams is about 30 deg. and there are 13 exposed, 3 of which are workable. These are 5 ft., 23 ft. and 49 ft., 6 in. in thickness, respectively.

Present Development

The present stage of the work is largely one of development, notwithstanding the fact that at Ma Chia Kow, a coal reserve has been found which will guarantee an output of 3600 tons per day for a period of 20 years. The management contemplates a huge output in the near future, and even though the present stage of development is a mere fraction of what they hope for, after the completion of the present shaft-sinking operations and their underground connections, the engineers feel justified in expending the capital required for the present elaborate equipment. Besides the parent shaft at Ma Chia Kow, there are three other pairs of shafts situated along the strike of the seams at intervals of about 3300 feet.

*Paper on "The Coal Fields of Northeastern China," by Noah Fields Drake, A. I. M. E., Feb., 1901.

The coal is characteristic in quality of that found throughout the district. It is of uniform grade, has qualities which make it well suited for steam purposes and is especially well adapted for coke manufacture. The coal has the disadvantage of being very friable. Two typical analyses of the coals are given as follows:

	No. 12 Seam Slack	No. 12 Seam Lump	No. 9 Seam Slack	No. 9 Seam Lump
Moisture	1.30	1.52	0.96	0.80
Vclatile matter	23.60	25.12	26.56	27.50
Fixed carbon...	59.86	53.06	56.65	51.70
Ash	16.24	20.30	15.84	20.00

The surface equipment recently completed at the Ma Chia Kow shaft is as uptodate in point of efficiency for the economical handling of material as may be found in any part of the world. A characteristic feature noted in every industrial plant laid out by trained German engineers, is the thoroughness with which all details are worked out. To an American, visiting this plant who is familiar with the current practice at home the most noticeable feature is the very substantial nature of the surface structures and the machinery equipment, which seems to point to a policy that takes no regard for the consideration of the financial balance and adjustment of ultimate profits that would involve a limit to first cost expenditure.

The policy of great permanence prevails throughout the plant. This appears to be the practice in Europe, particularly in Germany and this mine may serve as an example of how European practice differs from that of the American operators. The buildings are roomy and sub-

stantially built of brick. The office building, here as in all important Chinese establishments, is an elaborate one. In the eyes of the Chinese, this building must by all means come up with their ideas of the fitness of things by having it made to look as pretentious and dignified as possible. A large reception room with a number of ante rooms is always required for guests and business visitors.

Power Plant

The boiler house presents a typical illustration of the splendid surface equipment of this plant in general. There are seven fire-tube boilers of the Lancashire type which carry steam under a pressure of 180 lb. per sq.in., each having a heating surface of 1300 sq.ft. and provided with superheaters. The superheaters take the place of the economizers, found at most large boiler plants and the experience of many engineers shows them to be the most satisfactory in efficiency as well as in ease of operating and cleaning. In the firing of boilers, it is to be noted that here, as at many other plants where labor is plentiful, advantage is not taken of its cheapness. Firing is done by electrically operated mechanical stokers. The coal for firing is conveyed direct from the shaft house over a steel trestle and dumped in reinforced concrete bins over the boilers.

The power plant contains one unit, a compound engine and generator set of 1250 kw., which provides all the power required for running the Ma Chia plant and for furnishing lights for the other mines. A second similar unit will be installed later and also a low pressure steam turbine which will utilize the exhaust from other engines which may be run condensing or non-condensing. The voltages supplied are either 3000 or 500 according to the size of the motors, while the lights take 110 volts.

Hoisting, Ventilating and Pumping Machinery

Electric power is used in all departments of the mine except for hoisting. Eventually with the growth of the adjoining mines, it is planned to make the Ma Chia Kow plant a central power station to furnish power and light for all the works of the company.

For ventilation, the mine is provided with a main airway 4x6 ft. situated 33 ft. above the main level from which auxiliary air passages provide the circulation to the working faces and thence by way of the main haulageway to the upcast. The ventilating fans are high speed, electrically driven and two in number having capacities respectively of 87,000 and 123,000 cu.ft. per minute.

For handling the mine water, a main pumping station is being put in at the lower level, where three, electrically driven, centrifugal pumps will be installed having a capacity of 88 cu.ft. per minute each. At present the mine is making 123 cu.ft. of water per minute which is handled by one high pressure centrifugal pump and a sinking pump hung in the main shaft. The capacity of this sinking pump is 88 cu.ft. per minute and it is lowered up and down by an electric gear-driven hoist.

View Showing Surface Plant to the Left and General Offices to the Right

The air compressor is of the straight line type and has a capacity of 5300 cu.-ft. per minute. The compressor plant will be added to as it is expected that air winches for underground hoisting as well as air drills will be used to a large extent in the future operations.

Shaft Equipment

The main shaft has an inside diameter of 18.6 ft. and a depth of 690 ft. The lining is of a very substantial nature, consisting of hard limestone blocks trimmed and cut to conform with the curvature of the shaft and placed in a double layer, giving a lining about 18 in. in thickness. The auxiliary shaft, the wooden head frame for which may be seen in the accompanying illustration has a depth of 350 ft. and an inside diameter of 11 ft. When the installation is completed for the main hoisting shaft, the auxiliary will be used only for an airshaft. A glance at the illustration will show how the coal is being temporarily hoisted from this shaft, conveyed to an electric elevator and thence to the coal handling floor of the shaft house.

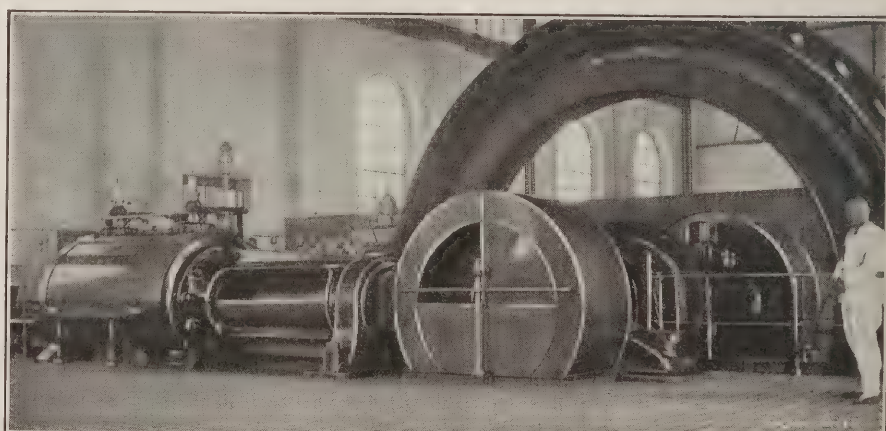
The main shaft has four compartments, all of which are to be used for hoisting coal. There is a cage for each compartment having four decks, each deck accommodating two cars each having a capacity of 0.55 tons of coal each.

To facilitate the speed of hoisting there are double landings at the underground stations and in the tipple, the arrangement allowing for two decks of loaded cars and two decks of empties being transferred at the same time. The cages are then moved a stated amount and the two remaining decks of each cage are taken care of in the same way. In the tipple house, of the two landings, the upper one is the auxiliary, from which the loaded cars are being lowered to the main floor by means of a small electric elevator. A similar arrangement is provided for at the underground loading station.

Three principal grades of coal are produced, the mine product being dumped by the ordinary car revolving tipple, on a travelling iron belt where boys usually do the picking, and thence over shaking screen. These screens feed directly into freight cars, which are hauled by the company's own locomotives to the main railway line 9 miles distant. The maximum capacity of this plant is 4800 tons per 16 hours.

The Timber Supply

The underground workings present another example of the long life and



Interior View of the Lanchow Mining Co.'s Power Plant

permanence which is expected of the plant, such as we are not accustomed to seeing in America even in the old producers. Advantage is taken of the cheapness of labor and particularly of the skill of the Chinese as masons. All main haulageways are supported by massive masonry lining, consisting usually of brick walls and an arch made of limestone blocks; reinforced concrete is also used to a certain extent.

The timber used in the temporary openings is an inferior grade of Chinese wood, which is crooked and knotty. As the central portion of China is practically deforested, the item of supplying timbers for mining purposes must necessarily be an expensive one and in most cases, recourse must be had to masonry supports where practicable. Here it may be pointed out that the native burned bricks of China are of good quality and very cheap.

NEAR VIEW OF STEEL HEADFRAME

For the future timber supply the company has already planted over 1,250,000 trees consisting mostly of acacias. These trees will grow from 4 to 6 in. in diameter in 5 years time and while they will only furnish timber of an inferior quality for mining purposes their planting will be profitable in other ways as the country is practically treeless.

System of Mining

The workings are opened up by a main haulageway parallel to the strike, and on the footwall side. Blocks of coal are exposed having 100 ft. along the strike and a length along the 40 deg. dip, corresponding to 165 ft. vertically. The filling method of mining is used throughout as the Chinese authorities object to having the surface disfigured by the caves resulting from subsidence, an occurence which would follow to a very considerable, if not a dangerous degree in the mining out of such thick seams. The seams encountered thus far have been regular in strike, dip and thickness. With the filling method in use, the system of regular extraction and watchful supervision over the laborers is not so necessary, as would be the case in mining where roof settlement plays so prominent a part. This adds to the safety of the workmen and to the ease in handling a large force of unskilled Chinese labor.

The mining of a block of coal is commenced at the base, a slice about 6 ft. in width being extracted horizontally from the roof. The coal is then conveyed in cars, or in baskets, by coolies to the temporary inclined hoisting station, from whence it is lowered or raised, as the case may be, to the main haulageway. Both compressed air and electric operated winches are used for this purpose. When a bench of coal is removed, extending across the width of the seam, the space is filled with waste rock which comes from the dead workings or from limestone quarries on the surface. The waste is shot down through chutes, which also serve as airways.

The coal is mined by the contract system in which Chinese contractors are used. There are at the present time 1200 men at work with the contracting force and 800 men employed by the mining company. The contractor is paid 18c. gold for slack and 22c. per ton for lump. Crosscutting, timbering and brick lining is paid for by contract at so much per meter.

Competition and Over Production

Owing to an over production of coal and coke in the North China coal areas, the Lanchow Co. has been suffering from competition which carries away the profits. It is hoped that the Chinese will eventually construct a shipping port, and with this a line of steamers of adequate size, that will give them more independence in disposing of their products.

To look into the future that lies before this company, it may be mentioned that there are iron ore bodies situated from 10 to 15 miles away from the coal mines which are said to contain large quantities of a good grade of iron ore. Negociations have already been under way towards getting foreign capital to invest in the development of these bodies of ore and the building a complete steel plant. The present company, with such an enlargement in the scope of its work, would then assume great importance as an iron and coal producer and become a factor in the ever increasing industrial development of China.

Permanent Board of Arbitration

By E. Jacobs

A joint application has been made by the official representatives of the Western Coal Operators Association of Canada and District 18 of the United Mine Workers of America, respectively, for the appointment by the Federal Department of Labor, Ottawa, of a chairman of a permanent board to which differences between the western coal mine operators and their employees are to be referred in the event of the parties not first agreeing without such reference.

For some years it has been customary, when disputes arose, for one or both of the parties concerned to apply for the appointment by the department, under the "Industrial Disputes Investigation Act," of a Board of Conciliation and Investigation for each individual dispute in which the services of such a board were invoked, the procedure being for each party to name its representative on the board and in the event of these two not agreeing upon a chairman, the department to choose one. When the long dispute of last year, which extended over nearly eight months, was brought to a close, the desirability of having a permanent board was mutually recognized, and now the department has been asked to name a chairman in accordance with the understanding then reached.

Seven Thousand Men Affected

The Western Coal Operators Association comprises in its membership most of the operators of coal mines in Alberta and the Crow's Nest District of British Columbia situated along the main transcontinental line of the Canadian Pacific Ry. Co. and its Crow's Nest line. District No. 18 of the United Mine Workers of America has branches throughout the area thus indicated. A general strike of employees at all the coal mines and coke ovens in District No. 18 involves the cessation of work by approximately 7000 employees, beside throwing out of employment others, such as train crews, not directly connected with disputes between operators and employees. The desirability of establishing a permanent board, having the confidence of both parties and sufficiently familiar with local conditions to enable the speedy settlement of differences, is generally conceded, so that there may not again result such a great loss to both parties immediately concerned, and to consumers of coal generally, as was the case last year.

Kentucky Mining Institute

The next meeting of the institute will be held at Lexington, Ky., June 10 and 11, as noted in COAL AGE of May 4, p. 969.

Electric Power Plants for Mines

By Henry D. Jackson *

The degree of remoteness from other plants and the probable life of the mines are two most important factors in determining the general type of electric plant for a coal-mining operation. Low fixed charges, attained by the use of inferior machinery, may be more than offset by the high operating costs which are entailed. General and detailed considerations regarding power-plant design.

Electric power for use in coal mining operations may sometimes be purchased to advantage from an established source but usually must be generated on the ground where it is required. As a rule, coal mines are not so situated as to enable their operators to purchase power at a price which compares favorably with that at which they can produce it for themselves.

Not infrequently, however, conditions are such that a number of small operations can profitably combine in the erection of a central station, from which power is furnished to each plant according to its needs. In an arrangement of this kind, it is a comparatively easy matter to determine the proportion of the total cost that each operation should pay by installing meters, either at the central station or at each of the receiving stations.

Owing to the more or less isolated location of the usual coal-mining operations, the prevailing arrangement for supplying electric power consists of a generating station for each plant, although not necessarily for each mine, as there are frequently a number of separate openings, subsidiary to one principal operation.

Probable Life of Plant Important

In determining the general character of a power-plant installation of this kind, the probable life of the mining operation is of prime importance. If the supply of coal is likely to be worked out in a comparatively short time, the installation should in general be inexpensive, as in the end a considerable portion of the building and apparatus will probably have to be abandoned. It is therefore advisable to build a plant which, while satisfactory for the time it is likely to be in use, will not represent any great sum of money at the time it has to be abandoned.

The same criterion does not apply, however, to the item of machinery, or at least not to an equal extent, because this part of the equipment probably need not be abandoned and it is essential that the engines for a power installation should be strong and reliable as well as desirable that they should be of comparatively low cost. Unfortunately these two items are not as a rule entirely reconcilable. A strong and reliable engine means good workmanship, material and design and is usually fairly high in cost.

It always should be kept in mind that while apparatus of low initial cost entails correspondingly low fixed charges, on the other hand, it is extremely likely to mean high operating costs. Generally, low priced engines require an excessive amount of steam, and the capacity of the boilers must consequently be increased, which fact acts to offset the saving on the engines. Also, the maintenance charges on an inferior machine are great because of the repairs which are inevitably required by an engine that is poorly designed and constructed. Another item of expense is that resulting from the frequent shut-downs which are necessary in order to effect these repairs.

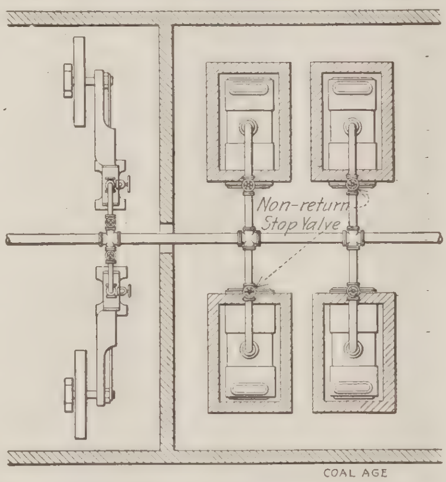


Fig. 1. Steam Main and Connections

Fixed Charges vs. Operating Cost

Therefore, in selecting the engines which are to be installed, it is essential that the questions of first cost and operating cost should carefully be considered and balanced. The load which is likely to come upon the engine through the year should be estimated as nearly as possible. On one hand, is the comparatively expensive engine with low steam consumption, small repair costs, high fixed charges on the engine and reduced fixed charges on the boiler plant. On the other hand is the comparatively low-priced engine with correspondingly high operating costs and high fixed charges on the larger steam plant which is required. Figures should be obtained on engines of different types and the operating costs and fixed charges carefully worked out. The same method of procedure should be followed out with reference to the boilers and other apparatus, until the entire plant is carefully covered.

In regard to electrical apparatus, it is equally important in this case to consider whether it is cheaper in the long run to install a direct-connected generator or a belted generator. The lower efficiency of the belted unit together with the greater space it requires, thus entailing additional cost for building and foundations, must be taken into account in comparison with the smaller building and foundations required by the direct-connected outfit of higher first cost. The generator itself should be purchased on exactly the same basis as the engine. A low-priced generator usually means exorbitant repair costs, and a high-priced generator may mean excessive fixed charges. These items must be balanced in order to obtain the best results.

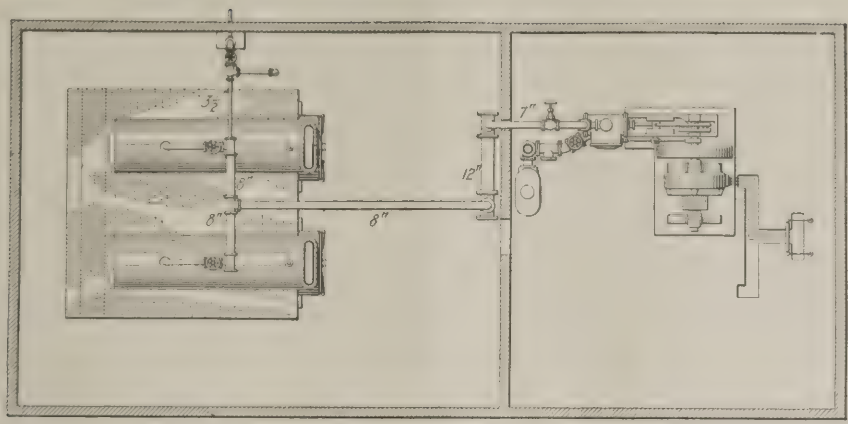
Simplicity of Arrangement Desirable

In deciding on the general arrangement of a plant it is important to secure the simplest practicable form of layout, in order to insure a low first cost. Simplicity, however, does not mean the cutting out of essential features. The plant should be carefully designed to avoid, as far as possible, all likelihood of breakdowns. The best material and fittings consistent with the purpose and life of the installation, should be used throughout. A breakdown due to imperfect or inferior material will result in a loss far greater than the difference in cost between inferior and good material. Particular attention should be paid to facilities for receiving coal and for handling supplies and repair parts, also for the removal of ashes.

If more than one unit is installed, every precaution should be taken to enable the several units to be operated independently so that repairs can be made to one set of engines or boilers while the others are in operation. Inter-connections between boilers and engines should be arranged so that any boiler or set of boilers can be used by any engine.

To insure continuity of operation, automatic non-return stop valves should be placed on every boiler, as it is frequently found that a boiler gives out in one way or another and allows the steam from the other boilers to blow through it, if this precaution is not taken. At prac-

*Consulting engineer, associated with Timothy W. Sprague and Frederic H. Keyes, Boston, Mass.



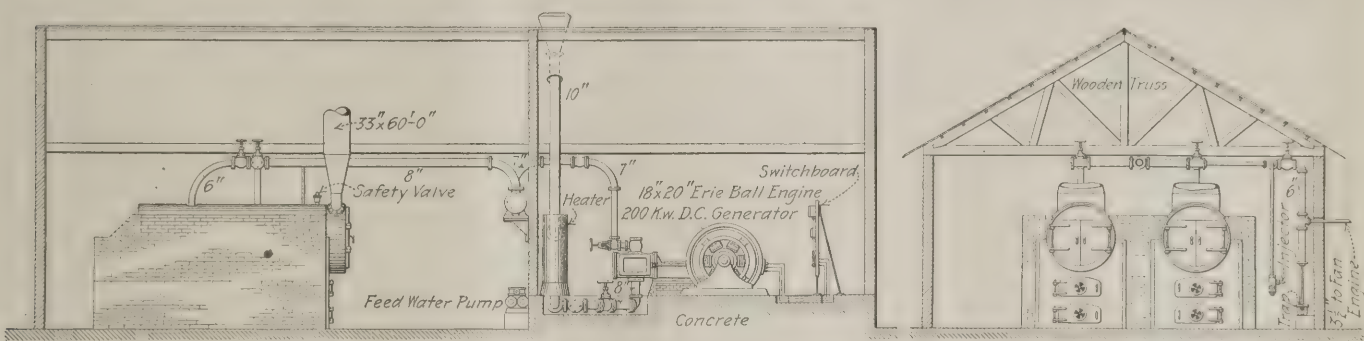


FIG. 2. SIMPLEST POSSIBLE FORM OF POWER PLANT, ALSO SHOWING DRAIN FROM STEAM LINE TO FAN

tically all mines it is quite essential that fans, pumps, and frequently the hoisting engines should always be in operation; if non-return stop valves are used, an accident to any one boiler will allow the other boilers to remain in operation unless the accident is so serious as to totally destroy or wreck the whole plant.

The piping between engines and boiler room should be as short and direct as possible, and every provision should be made to take care of expansion in the steam lines. All steam piping should be carefully drained, and valves should be so arranged that no water will be held in the pipe when the valves are closed. All pockets and loops in the piping should be drained by means of traps, and the water returned to the boilers if practicable.

Feed Water Economy

Frequently, one of the greatest difficulties in the coal fields is found in obtaining good water for the boilers, and therefore no water which has been purified by being made into steam should be thrown away if it can safely be returned to the boilers. "Safely" is here used advisedly, as it is often found that the exhaust steam which has passed through engines is contaminated with oil to such an extent that it would be unsafe to return it to the boilers. Under these conditions the use of closed feed-water heaters, or open heaters with oil separators, will allow the heat in the steam to be delivered to the feed water.

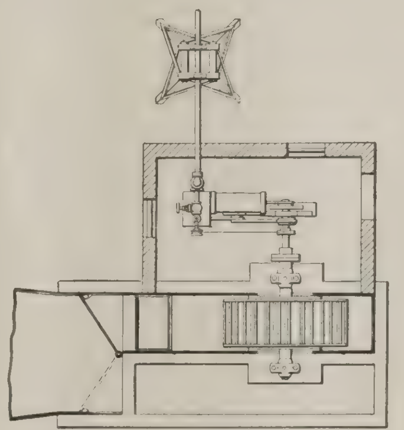
The question of whether or not to operate a plant on a condensing basis, depends entirely upon the supply of water available for condensing purposes. It is frequently found that while there may be a scarcity of water suitable for boiler supply, there is at the same time plenty of water available for cooling purposes. Under these conditions it is usually wise to operate condensing since the consequent decrease in the size of the boilers and the smaller consumption of fuel and water soon pay for the additional cost of the condensing apparatus. Then too, it is frequently possible to install small turbo-generators which are lower in cost than a reciprocating-engine set of equivalent capacity because of the smaller amount of room which they require and the higher speed at which they operate. These allow the return of all the water of condensation to the boilers because no oil comes in contact with the steam, in an apparatus of this character.

It may not be out of place here to refer to the use of steam driven fans. These are required in a number of instances because it is desired to operate the ventilating plant when the main electric generating unit is shut down. It may frequently happen in a case of this kind that the fan is located at some distance from the power station and requires the installation of a long steam line. Every precaution should be taken to absorb the expansion and contraction taking place in a line of this kind and in such a way as to avoid undue strain upon the pipe itself or upon any of the buildings.

Design of Long Steam Line

Furthermore, the condensation taking place in a pipe line of this sort is likely to prove a source of considerable trouble. It is dangerous to allow the condensed water to reach the engine and it is equally dangerous to allow it to get back into the main steam line. In the first case it is liable to wreck the machine and in the second case, a slug of water in the main line may rupture the fittings. Provision should be made (1) for draining this water as it forms, and (2) for preventing it from getting to either the engine or the main steam line in case the drain fails to operate.

Another point which has to be taken



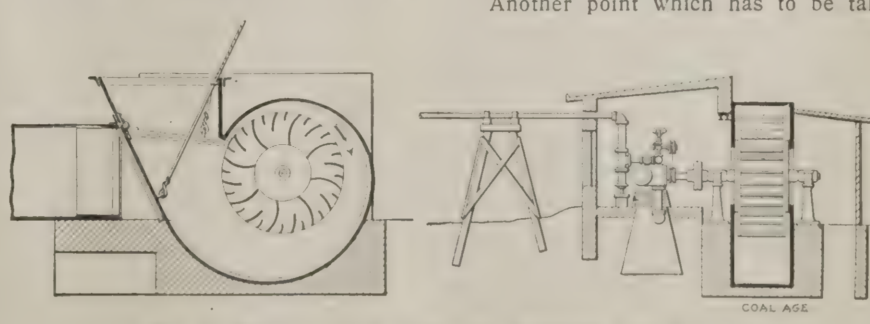


FIG. 3. STEAM-LINE ANCHORAGE, RECEIVER AND TRAP

into account in connection with a long steam line of this kind is the possibility of excessive vibration due to the intermittent flow of steam which results from supplying a reciprocating engine. This vibration frequently can be avoided by installing, at or near the fan engine, a receiver having sufficient capacity to supply the engine with steam, without materially lowering the pressure in the receiver, and thus allowing a continuous flow through the pipe. Figs. 2 and 3 show the beginning and end of a pipe line which runs to a fan engine. The anchorages and also the methods employed for preventing water from getting to either the engine or the main pipe line are illustrated.

Receivers and Steam Traps

In the end elevation of the power house, Fig. 2, it will be noted that there is shown a vertical pipe from which the fan engine line is taken off at about midway of its height. This pipe acts as a receiver for water which may condense in the steam line. The water is drained off from the pipe by means of a steam trap. At the fan engine, a similar pipe will be noticed which serves a like purpose and also acts as a receiver for smoothing out the fluctuations of the steam in the pipe line.

A layout of the power plant proper, in its simplest form is shown in Fig. 2. Provision is made for an additional boiler and engine. In case it is desired, an extra main may be provided for carrying steam from the boiler room header to the engine header, thus giving more assurance of a steam supply to either engine in case of accident. However, this arrangement is in most cases unnecessary if care is taken to purchase high grade material for the simpler form of layout.

It may be unnecessary to suggest that room should be provided in the boilerhouse for the removal of tubes from the boilers but it is not uncommon to find that in existing plants such provision has not been made. Another suggestion of demonstrated practical value is the use of a stop valve between the boiler and and the blowoff valve, in order to keep the latter in good condition. This is a point which is frequently overlooked, with the result that the blowoffs leak, stick and in general are the source of much inconvenience and occasionally a shutdown.

There is usually urgent necessity for a careful analysis of all water used for boiler feed purposes throughout the coal fields. Water in these localities frequently contains, in addition to the more usual scale forming material, impurities which will rapidly and seriously injure the boilers. Under such conditions it is advisable to use some system of feed water purification. Purifying apparatus will often save many times its cost in boiler repairs. Sometimes the system of water purification may be combined with a feed water heating apparatus.

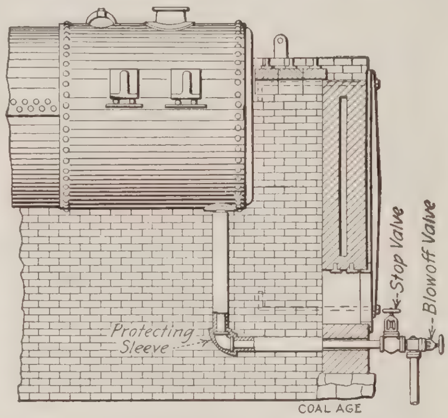

Fig. 4. Blow-off and Stop Valve

Feed Water Heating and Purification

The installation of a good feed water heater is always worth considering (1) because of the saving in fuel and (2) because it saves the boilers. Whether the open or closed type of heater should be selected, depends largely upon the conditions of service. The closed heater possesses the advantage that with its use oil cannot possibly be carried over to the boilers from the engine exhaust. On the other hand, if the water used contains salts which precipitate at a comparatively low temperature, the closed heater will soon become inefficient unless frequently cleaned, and under these circumstances it is usually advisable to install an open type heater, in which the salts can readily be thrown down and easily removed. In the latter case, oil in the steam may be taken care of by means of an oil separator.

The heater should usually be connected as shown in Fig. 6, that is, as a non-thoroughfare. This arrangement operates to prevent even the small amount of oil which may pass the oil separator from getting into the heater and consequently reaching the feed water. The amount of steam required for heating the water is usually only about one-fifth of the engine exhaust and this much will readily be drawn into the heater by the reduced pressure, which results from the condensation of the exhaust steam.

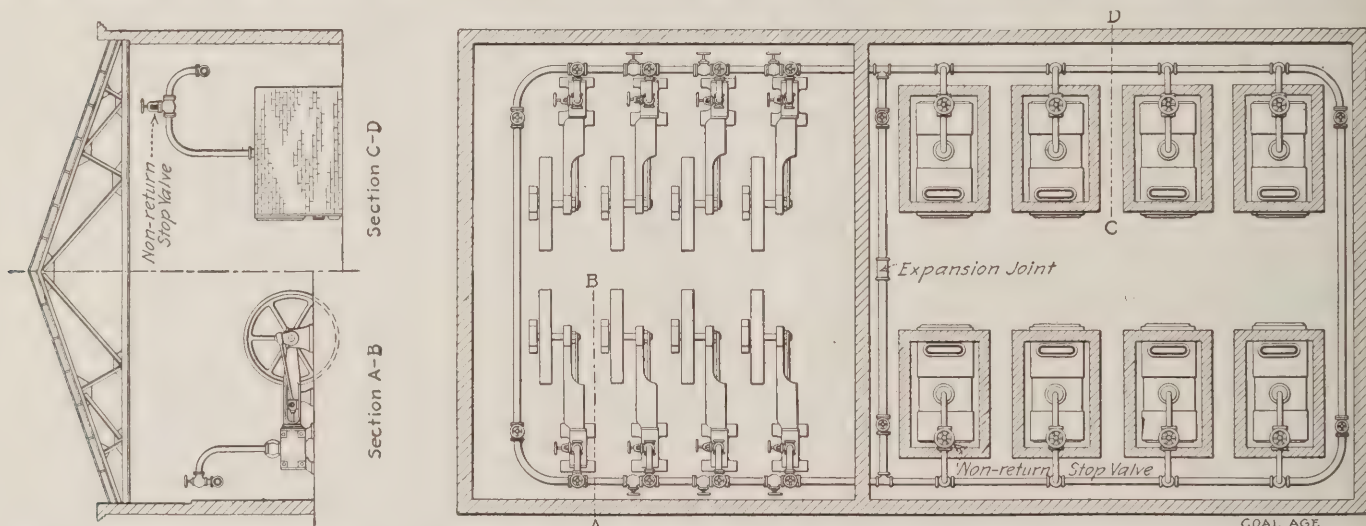

Fig. 5. The Ring System of Piping, Devised to Insure Continuity of Operation, Seldom Justifies Its Greater Cost

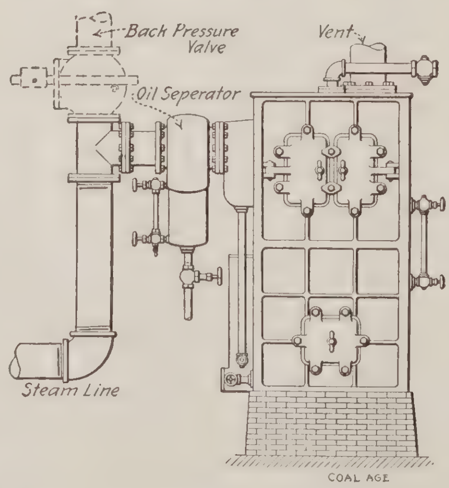

Fig. 6. Non-thoroughfare Heater

The Screening Problem in Illinois

By A. Bement*

An interesting review of the relative production of the different sizes in the Illinois fields. The results of a change in the methods of payment from a lump to a mine-run basis are graphically shown. The use of mechanical stokers by large consumers has materially strengthened the demand for the finer sizes and the author is inclined to the belief that these will eventually command the highest prices.

*Consulting Engineer and Coal Expert, 206 S. LaSalle St., Chicago, Ill.

The accompanying diagrams, Figs. 1, 2 and 3, show graphically the production of the various grades of coal in the state of Illinois. The output is shipped as mine-run, or prepared as lump, egg, nut and screenings, the latter mostly through 1¼-in. perforations. The output where division is made is more commonly separated into 1¼-in. lump, known generally as railroad coal, and screenings. In certain districts, however, notably the southern part of the state in Williamson, Madison and Macoupin Counties, a different separation prevails. The fine coal goes through a screen having 3-in. perforations and is then separated into five sizes which are washed and enter the market as washed and sized coal.

The Abrupt Decrease in the Production of Lump

Prior to 1898, lump coal was by far the principal product, as in the early days of mining there was very little demand for the fine sizes. Every effort was therefore made to produce as large a percentage of lump as possible and before the decrease in lump production occurred, just prior to 1900, as shown by Fig. 1, payment for mining was upon the lump coal basis. The drop in the curve illustrates the results of the change in the method of payment from the lump to the mine-run basis, which occurred at that time. Formerly, it had been to the advantage of the miner to produce as much lump coal as possible; with the mine-run basis of payment, however, this incentive was no longer present.

The result was the production of a very large tonnage in the form of screenings for which there was small demand and consequently they sold at a very low price; about 25c. per ton at the mine would probably represent the average. The rapidly increasing use of automatic stokers, however, gradually changed this condition by enlarging the demand for screenings to such an extent that the fine coal threatens to become the principal product, a condition just the reverse of that formerly existing.

The price of raw screenings, at the present time, is subject to great fluctuations. Within the past year, they have been as high as \$2.38 and as low as 20c. per ton at the mine, with an average of about 85c. for the year. This great fluctuation in price is due to the supply being so variable, as screenings are only made when lump coal is being produced, and are thus limited by the lump demand. At such times as the supply of screenings is inadequate.

Relative Production of Sizes

Diagram, Fig. 2, illustrates the respective percentages of lump, screenings, mine-run and egg coals produced since 1900. From this it will be seen that from 1906 to 1909 there was a marked falling off in the production of mine-run, due largely to the increasing demand for fine coal. Since that year, however, the percentage of mine-run has increased rapidly up to the present time while screenings show a decline. This is because the demand for screenings so much exceeded the supply that it was necessary in a great many cases to purchase mine-run and crush it.

The effect of the increasing percentage of mine-run is also apparent upon the lump coal curve, while that of egg coal shows a steady but moderate increase. One of the factors influencing the production of egg is that it is found to be a most satisfactory size to place in storage, a practice which is gradually becoming more common in the territory tributary to the Illinois coal fields.

Diagram, Fig. 3, is based upon the data presented in Fig. 2, except that a division is made of the fine coal into raw screenings and washed coal. This shows that the production of standard stoker fuel, or in other words, raw screenings, was in 1911 very much smaller than mine-run, while the washed coal output shows a steadily increasing gain. This washed coal in the form of screenings and the washed sizes is largely used in hand-fired furnaces and domestic fires, although there is a certain amount used in stokers, where it is felt that a superior quality of fuel is desirable.

There is a marked tendency toward an increase in the demand and price of the smaller sizes; thus the washed sizes Nos. 4 and 5, the former ¼x⅝ in. and the latter that which passes through ¼-in. perforations are in larger demand than are Nos. 1, 2 and 3. If this condition continues, the small sizes will soon command a higher price than the larger. This reasoning applies to raw screenings also, and a time may come when they, as well as all of the fine coal, will bring a price higher than that obtained for lump. If this comes to pass, mine-run coal will be at a premium, compared with lump, and on a par with raw screenings. In fact, raw screenings may command a slight premium over mine-run, as it would be more desirable for a power plant to purchase screenings which are coal in a crushed form than to buy mine-run and crush it.

Profiles Showing Fluctuations in Production of the Illinois Coals

The Hookworm and the Miner

By R. S. Ogilvie
and N. P. Brooks

It has been demonstrated in Germany that sanitary provisions can eradicate hookworm whether mines are dampened or kept dry. The authors declare that in omitting moistening to avoid ankylostomiasis, there is danger of replacing the disease by miner's consumption.

It is an indisputable fact that wet mines are much more widely infected than dry workings, but no one ever heard of an absolutely dry mine. We shall find a certain number of feeders in every underground operation of any extent and where we find them, if the temperature is suitable, the mine under the present lack of sanitary precaution will be almost sure to become infected with the larvæ of hookworm. The area of infection will be less but it will claim a certain number of victims each year.

A paper by J. Wroe (vol. 29, pt. 3, of the *Transactions* of the Institute of Mining Engineers) gives a few statistics as worked out by investigators for the coal mines of Germany. The following figures are the result of two years' study of the conditions in four German collieries. The Julia and Heydt mines are, in general characteristics, very similar. Both were dry mines and they had been sprinkled for several years in accord with the German law. By a special act all watering was stopped in the Julia while it was continued in the Heydt as before. At the same time, active treatment of the men and of the mine to eradicate the hookworm was begun in both. It consisted in treating all the feeders of water with milk of lime, in treating all the men infected and in, as far as possible, isolating the infected workers.

Examination	Men examined	Men infected	Percentage
First:			
Julia	1168	228	19.52
Heydt	928	166	17.89
Second:			
Julia	1088	16	1.47
Heydt	928	20	2.15
Third:			
Julia	1063	10	0.94
Heydt	886	13	1.47

Throughout the time between the first and third examination prophylactic treatment of the mine continued. The first two inspections were separated by a time space of one year. The second and third examinations in the Julia mines were 18 months apart but in the Heydt mine only 17 months.

How Larvae Were Destroyed in Two Normal Mines

The Recklinghausen Collieries Nos. 1 and 2 were more or less wet and had never been watered. No. 1 had a steep pitch and was a crowded mine.

RECKLINGHAUSEN COLLIERIES
Mine No. 1

Examination	Men examined	Men infected	Percentage
First	1141	144	12.76
Second (after 12 months)	1306	52	3.98
Third (after another 18 months)	1227	30	2.44
Fourth (after another 22 months)	1006	29	2.88

Mine No. 2

Examination	Men examined	Men infected	Percentage
First	1425	53	3.70
Second (after 12 months)	1826	14	0.77
Third (after another 18 months)	1766	4	0.22

These statistics of the Julia and Heydt mines show that in the watered mine there was a slightly larger number of men infected than in the unwatered mine, but the percentage was so small that if a larger number of operations had been taken the results might show that the difference was due to other causes than the presence of moisture. We think it would be safe to say that when using due prophylactic measures, we can disregard the slight danger which exists of increasing the hookworm disease amongst the miners and can spray and drive steam into the workings as much as we consider necessary.

Our study of the question has brought us to believe that the temperature, pitch of the seam, and general working conditions will be found to influence the spread of the disease much more than watering the mines. The latter certainly can have no bad effects if the scheme which we are offering is carefully carried out from the start or is introduced into an old mine. The sure way to guard our miners from infection of the hookworm is to prevent the mine soil from becoming infected with its larvæ.

Life History of the Worm

There seems to be no intermediary host necessary for the development of the parasite. The ovum is passed into the feces and there develops into larval form. It then reënters the human body and grows to an adult worm. The mode and route of entry are still under discussion but the majority now accept the theory that the larvæ enter through the skin, usually through the skin of the feet. The problem then is how to keep the ova from reaching the mine floor and if they are deposited thereon how to prevent their development to maturity.

One of the first things on the ground when a new shaft is to be sunk should be some form of sanitary to be used by all men employed in sinking. The form which we recommend is an incinerator, the McCaul being quite satisfactory as it will take care of a large quantity of material and is fitted with a privy cover.

As the work progresses there should be furnished stout galvanized-iron cans of 10 to 20 gal. capacity, each can being furnished with a tight-fitting privy seat which can be easily removed when the can needs emptying. As the work progresses and entries are opened up with accompanying working places, new cans should be installed as fast as needed in such places as will be easily accessible to the employees. When possible the cans should be set in the return air way. We would recommend the use of a sufficient number of sanitaries so that men in charge of the work can make one collection daily, replacing the used cans with others which are empty and sterilized. The privy cover can be transferred to the fresh can, an ordinary tight tin cover being placed on the full can while it is being taken to the surface.

Incineration

The incinerator building should be placed as near the exhaust shaft as possible and should be a sufficient distance from the intake shaft to prevent the gases from the burning excreta entering the mine. There should be a large steam chest into which the exhaust steam from the hoisting engine can be turned.

On bringing the cans to the surface they should be emptied at once into the incinerator, then placed in the steam chest and the steam turned on. The cans should remain there for several hours, the duration of the steaming being dependent on the amount of steam which is available. After cooling, if the cans need any further cleansing, it can safely be done anywhere with a hose or by some other means.

One Man Can Care for All Sanitary Needs

The expense of such a method should not be great. One man can easily look after the cans in a large mine or in two small mines if they are close together. The residue makes a good fertilizer and the use of it will nearly pay the running expenses of the incinerator. It will be hard at first to get the men to use the cans; but if the pit bosses and under-bosses insist, the change can be easily effected and there will not be any of these evil smelling, nasty places which are to be found in nearly every mine and the hookworm will no longer infest the intestines of the miners.

DISEASES OF RESPIRATORY TRACT

It is well not to lose sight of one danger in guarding the men from another. In every dusty mine a great deal of disease of the respiratory tract is found. Anthracosis or miner's consumption is more common than the hookworm disease, though it is not as serious an ailment. A dry mine would probably increase the number of sufferers from anthracosis, at least as much as it would decrease the number of hookworm patients.

Throughout an old mine the feeders should be thoroughly treated with milk of lime weekly. Men known to be suffering from the disease should be isolated as far as practicable and should be warned that they are a source of danger to their fellow workers.

Firing Shots in Still Air

By John Verner

No conclusion of value can arise from a comparison of explosions in different mines, when complete descriptions of these are not available. But some scientific deductions are permissible when two explosions occur in the same mine. By considering only manifestations in identical workings, the argument seems favorable to shooting in still air.

*Chariton, Iowa.

Mr. Rhys, state mine inspector of the 2d Iowa district, in his review of my paper on Iowa mine explosions[1], in the May 11 issue of COAL AGE, after citing a number of explosions in different Iowa mines, occurring with the fan running at its usual speed, reduced speed, or stopped entirely during shot-firing time, presents his conclusions that slowing down the fan before touching off shots does not lessen the force of the explosion, nor make it less destructive, and that the evidence is decidedly against my theory.

FAN SPEED AND VENTILATION

Even a cursory reading of Mr. Rhys' article makes it evident that the above conclusion cannot have any value, because it is based solely on the unessential matter of the fan's speed at different mines where explosions occurred. He does not give any consideration whatever to the actual condition of the ventilation and other influential factors existing in these mines when they exploded. At one mine the fan may be run at top speed, and yet the ventilation of the working places may be objectionable and the current feeble; at another mine the fan may not be running at all, and yet through the force of natural ventilation the working places may be found adequately ventilated and with a fair air current passing through them.

Some years ago, I found at the bottom of the downcast of a certain old mine, an entering air volume of 11,500 cu.ft. per min., with the fan running at 88 revolutions. After this old mine was closed down, the fan was placed at a new plant and produced 36,000 cu.ft. of air per min. at the reduced speed of 62 revolutions.

Supposing it had been possible under the adverse conditions existing in the old mine to produce a feeble explosion in its working parts, and supposing that under the favorable conditions prevailing in the new mine a disastrous and violent explosion had occurred there, would that justify the assumption that the difference in fan speed was a factor in determining the mildness of the explosion in the old mine and the great violence shown in the new?

To prove or disprove that an increase or decrease of draft tends to increase or decrease the violence of explosions, it is necessary that the tests to that end be made in the same mine and under otherwise identical conditions, or in consequence too many undetermined considerations will vitiate the results.

The opportunity for making such tests was afforded by the two explosions cited by Mr. Rhys, which occurred in mine No. 4 of the Cleveland Coal Co., on Jan. 5, 1901, and on Feb. 5 of the same year. I am well acquainted with all the features of these explosions, because I investigated them personally immediately after their occurrence. Mr. Rhys states correctly that the two explosions started in the same part of the mine and almost in the same place, that otherwise similar conditions prevailed and that their course was identical.

TWO CASES AND BUT ONE DIFFERENTIAL

There was, however, a marked difference in the effects. While the primary cause of the first explosion was apparently of greater power than that of the second, the second explosion showed much greater violence than the first as it extended toward the shafts. I was unable to discover any visible signs to account for this difference in effects, but I did find that the mean temperature on the day of the first explosion, Jan. 5, was 27.5 deg., and on the day of the second explosion, Feb. 5, 5.5 deg. Supposing that on both dates the fan was running at the same reduced rate of speed, it will be readily apparent to one conversant with the subject of mine ventilation that a drop of 22 deg. in the temperature of the air entering a mine means a considerable increase in the velocity of the air flow through the workings, and I can say that under the favorable conditions existing in No. 4 mine, this natural ventilating force became particularly effective, and consequently the draft facilities at the second explosion were materially better than at the first. Accepting Mr. Haas' rule that the magnitude of a dust explosion is measured by the availability of the air supply, other conditions being the same, the cause for the greater violence shown in the second explosion is reasonably accounted for.

THE BELIEF OF THE SHOTFIRERS

Mr. Rhys says: "Since 1902, the practice of slowing down the fan at firing time has become quite general throughout the state. Whether right or wrong, the belief in its protective value is such that it would be almost impossible to secure shotfirers in new mines, especially during the cold season, unless the fan was stopped or slowed down at firing time." Is it probable that such general and persistent belief can be founded solely on imagination? As a rule, the Iowa shotfirer is a man of intelligence and good judgment, and well trained in his hazardous work.

His daily opportunity to observe results under varying conditions enables him to become a competent judge as to whether the conditions found tend toward safety or lead into danger. When, after a test of ten years, he still declares his belief, that the reduction of draft at firing time is beneficial, his judgment should be received with due respect and consideration, especially in the absence of any proof showing that it is at fault.

SLOWING THE FAN AT LEAST A PALLIATIVE

There is no direct proof that the practice of slowing down the fan at firing time has prevented the occurrence of an explosion in an Iowa mine. As a palliative, it has been and is now considered useful, but its greatest merit lies in the fact that its general trial in this state for ten years has brought to the Iowa shotfirers and many miners the firm belief, strengthened by personal observation and experience, that although ample and thorough ventilation is desirable and necessary, it brings with it an element of danger that demands careful consideration in providing for a mine's safety. That belief should be implanted in every mining community in this country.

West Virginia Coal Mining Institute

The ninth semi-annual meeting of the institute will be held in Charleston, W. Va., June 6, 7 and 8. A program has been arranged as follows:

Thursday, June 6, 10 *a.m.*—Address of welcome, by Gov. William E. Glasscock; president's address, by Frank Haas; five-minute talks by the vice-presidents; "The Use of Gasoline Motors in Coal Mines," by A. J. King, mining engineer, Charleston, W. Va.

2 *p.m.*—"Quality and Quantity of Mine Air," by Karl F. Schoew, mine inspector, Fairmont, W. Va.; "Points of Interest in Mine Ventilation," by J. T. Beard, associate editor COAL AGE, New York, N. Y.; "Successful Store Management in Relation to Mining Communities," by Charles H. Lantz, general manager, Buxton & Landstreet Co., Thomas, W. Va.

8 *p.m.*—"The Projection and Development of a Mining School," by E. N. Zern, professor mining engineering, West Virginia University, Morgantown,; "Mine Accidents and Their Prevention" (stereopticon), by Ira D. Shaw, international secretary Y. M. C. A., Pittsburgh, Penn.

Friday, June 7, 10 *a.m.*—"Coal Mine Accidents," by David Victor, chief mine inspector, Consolidation Coal Co., Fairmont, W. Va.; "Safety in Coal Mines, Especially in West Virginia," by F. C. Cornet, mining engineer, Charleston, W. Va.; "Some Experiences in the Drainage of Mines," by C. E. Tucker, superintendent, Consolidation Coal Co., Frostburg, Md.

2 *p.m.*—Trip to the Blue Creek oil fields, 15 miles from Charleston, on the Coal & Coke Ry. Special train will leave Charleston at 2 p.m. and return at 5:30 p.m.

8 *p.m.*—Banquet at Hotel Ruffner, Toastmaster: Gov. William A. McCorkle. Speakers: Hon. George E. Price, "Railways and Coal"; Hon. Malcolm Jackson, "Laws"; Hon. Henry G. Davis, "Pioneer Days"; Dr. J. A. Holmes, "Scientific Research"; Dr. I. C. White, "Geology"; Hon. L. E. Tierney, "Practical Mining"; J. C. McKinley; Hon. Z. T. Vinson; Frank Haas, "Institute Work"; Hon. George S. Laidley, "Education"; Dr. J. E. Robbins, "Village Sanitation."

Saturday, June 8, 10 *a.m.*—"Lubrication," by L. A. Christian, consulting engineer, Keystone Lubricating Co., Pittsburgh, Penn.; "Required Qualifications of a Successful General Manager, from a Superintendent's Point of View," by T. H. Huddy, general superintendent, Boomer Coal & Coke Co., Boomer, W. Va.; question box; reports of committees.

The sessions will be held in the Senate room of the State House, at Charleston.

Coal Mining Institute of America

The summer meeting of the institute will be held in Johnstown, Penn., June 25 and 26, and will be devoted to a discussion of practical mining problems. The institute headquarters will be at the Crystal Hotel and sessions will be held in Library Hall. The following program has been arranged:

Tuesday, June 25, 10 *a.m.*—Address of welcome, by C. S. Price, president, Cambria Steel Co. President's address, A. W. Calloway, general superintendent, Rochester & Pittsburgh Coal & Iron Co. Business session. Symposium: Weak links in the operating chain, (a) executive officers, (b) mine superintendents, (c) mine foremen and assistants.

1:30 *p.m.*—Continuation of morning program. Question box, State Mine Inspectors Nicholas Evans and T. W. Williams presiding. The afternoon session, from 3:30 o'clock on, will be devoted to the discussion of practical questions submitted by members of the institute.

6 *p.m.*—Institute dinner. Toastmaster: H. S. Endsley. Speakers: John Fulton, C. C. Geer and Frank Gray.

Wednesday, June 26, 9 *a.m.*—First-aid demonstration and contest, in charge of Thomas B. Dilts, mining secretary, Pennsylvania State Y. M. C. A., and Harvey J. Hill, special secretary, Y. M. C. A. Judges: J. A. Metzgar, M. D., Latrobe, Penn.; F. C. Keighley, Uniontown, Penn.; H. M. Wilson, engineer in charge U. S. Bureau of Mines, Pittsburgh, Penn.; F. W. Cunningham, state mine inspector, Charleroi, Penn.; A. C. Beeson, chief engineer, Pittsburgh-Buffalo Co., Pittsburgh, Penn. The Coal Mining Institute of America will award an engraved silver cup to the winning team.

12 *Noon*—The Cambria Steel Co. will tender a complimentary luncheon to members of the institute and a sight-seeing trip has been arranged. The party will be taken by special train through the mills and works of the Cambria Steel Co.

If the institute so decides an evening session can be held in Library Hall. Charles L. Fay, Wilkes-Barre, Penn., is secretary-treasurer. M. G. Moore is chairman of the committee on local arrangements.

Alabama Coal Operators Association

The annual meeting of the Alabama Coal Operators Association is to be held at Birmingham, June 11, at which time officers will be elected. The annual outing of the association is to be held June 12, at the Docena mines of the Tennessee Coal, Iron & R.R. Co. near Birmingham.

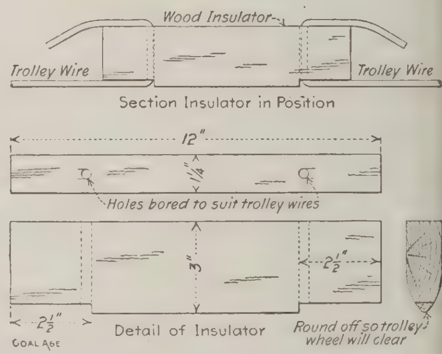
Among the speakers who will address the meeting will be Dr. S. C. Hotchkiss of the U. S. Health and Marine Hospital Service; Morris Knowles, sanitary engineer for the association; Dr. Robert Nelson, city health officer, and H. M. Wilson, chief engineer of the U. S. Bureau of Mines.

An interesting feature of the outing will be an exhibition of mine machinery, safety appliances, mine lights, permissible explosives, rescue apparatus, fireproofing, brattice cloth, etc.

A Home-made Trolley Wire Section Insulator

By Arthur O'Brien

A section insulator for coal-mine trolley wires, can readily be made from a stick of oak or maple, as shown in the accompanying illustration. Although insulators of this type are simple in construction and cheap to make, they have shown themselves to be thoroughly reliable in every-day service around the mines.



Trolley Wire Section Insulator

Maple is the best wood for the purpose, but oak is frequently used, because it is more likely to be available around mining plants. Where it can be done, it is a good plan to boil the stick, after it is worked into shape, in paraffin, or to paint it with an insulating varnish that will soak into the wood. The only advantage that appears to come from [illegible] treatment, is that moisture, which might in time split the wood, is kept from entering it. The device gives quite satisfactory service without treatment of any kind.

The dimensions given in the sketch are approximate, and may be varied within reasonable limits to satisfy local conditions. The length, however, should not be much less than 12 inches.

When installing the device, care must be taken to so bend the trolley wires that it will stand vertically. Experience has shown that merely turning the ends of the trolley wires over, as shown in the illustration, provides sufficient support for the insulator. The trolley wires should be supported by an insulating hanger and clamp at points a few feet away on each side of the section insulator.

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Explosion Prevention by Oxygen Reduction

The prevention of explosions by a reduction of the oxygen content of the mine air was recently advocated by J. Harger in a lecture before the Geological and Mining Society at Manchester University on Feb. 27.

In the course of the lecture, Dr. Harger stated that neither a candle nor a lamp would burn in air in which the oxygen was reduced to 17 per cent., yet a man could work continuously in such an atmosphere and not observe or feel any difference in his condition from the reduction of oxygen. No shortage of oxygen was noticeable until the reduction reached 14 per cent., while at 12 per cent. the shortage was most marked, and at 7.5 per cent. life was extinguished.

Dr. Harger said that air containing 17 or 18 per cent. of oxygen, with a moderate amount of carbon dioxide up to 1 per cent., was entirely suitable for the human requirements and was as good as ordinary air. A man breathing atmospheric air (21 per cent. oxygen) exhaled a mixture of gases containing 16.5 to 17 per cent. of oxygen and 4 to 3.5 per cent. of carbon dioxide. The reason this was expelled was not because more oxygen could not be taken by the lungs, but, because the depth and frequency of breathing were unconsciously regulated to keep the carbon dioxide within the lungs at 5.5 per cent. The slightest increase in the carbon dioxide was sufficient to excite the nervous center, which regulates breathing, to increased activity.

To prevent explosions, Dr. Harger suggested the taking of flue gas, purified from all harmful ingredients, the mixing of them with fresh air entering the mine workings in the proportion of one part to 30 of fresh air or one part to 15 for the most dangerous mines.

In the discussion which followed, the colliery managers and engineers took a prominent part, and they argued that there is often a great difference between laboratory tests and conditions in extensive workings. What effect would the reduction of oxygen have on workings far removed from the shafts? Must we unlearn all that we have learned about ventilation and the need for a maximum percentage of oxygen? Dr. Harger in reply stated that on the first application he would reduce the oxygen to 20 per cent. in ordinary mines, while in the dangerous mines he would reduce it to 19 per cent.

Precise Surveying for a Connection

By Frederic C. Noble*

Every coal engineer, at some stage of his career, is called upon to "make a survey connection." These connections are most often of some important haulageway, and it is essential that the results be comparatively accurate. This paper describes the ultimate refinement in work of this character as applied on one of the most important engineering projects of the day.

The following is a description of the surveying methods used in constructing the tunnel under the East River (at New York) between South Ferry, Manhattan, and Joralemon St., Brooklyn. This tunnel was begun in March, 1903, and was opened to traffic in January, 1908. The tunnel consists of two parallel single-track tubes, of the usual cast-iron ring construction having an interior diameter of 15½ ft. The distance between centers is 28 ft. under the river and 26 ft. in Joralemon St. The Manhattan headings were driven from a double shaft in Battery Park. The Brooklyn headings were driven from two shafts (one over each tube) in Joralemon St., about 1200 ft. from the water front. Between the shafts, a distance of about 6000 ft., there are three tangents in the tunnel line, the middle or river tangent being joined to the Manhattan and Brooklyn tangents by curves of 4500 ft. radius (Fig. 1).

The intersection of the south tube lines of the Joralemon St. tangent and the Manhattan tangent produced was located on the roof of a dock warehouse at the foot of Joralemon St. It was necessary to determine the exact distance between this intersection and a point of known stationing on the south tube line in Manhattan, and this required a triangulation survey. It was apparent that no base line of suitable length could be laid out in the vicinity that could be measured directly from end to end as one of the sides of the triangulation system. Although the ends could be located on roofs, so as to be seen from each other, the measurement had to be made along a broken line.

The Triangulation System

A reconnaissance showed that a suitable base, about 3000 ft. long, might be obtained on the Brooklyn waterfront north of Joralemon St. The southern end of the base chosen was the above-mentioned intersection of the south tube lines. Its northern terminus was also located on the roof of a warehouse. Each of these points commanded a view of the other and of the adjoining waterfronts of Manhattan and Governor's Island, and, accordingly, were suitable for triangulation stations. In Manhattan, because of intervening buildings, it was found impracticable to locate a triangulation station on the south tube line in the vicinity of the shaft so that it would be visible from all the other stations. On this account two elevated points on the roofs of near-by buildings, one on each side of the Manhattan tangent, were chosen as triangulation stations, and carefully referenced to the point of known stationing on the south tube line, which was visible from them. On the northerly sea-wall of Governor's Island, two triangulation stations were chosen which marked the extremities of a shorter base used two seasons before in making a preliminary triangulation of the tunnel line. It was desired to include this base in the system so as to have an independent check on the measurement of the Brooklyn base.

The foregoing arrangement gave four fairly well proportioned quadrilaterals, the Brooklyn base forming one common side. In the system there were no angles of less than 26° or more than 78°, and the ratio of length of base to the distance sought was about 1 : 1½. By having four

Note—Abstract of a paper (copyright) presented before the American Society of Civil Engineers (New York), Feb. 7, 1912. The paper is entitled, "Notes on a Tunnel Survey," by Frederick C. Noble, and is published in the December issue of the "Proceedings" of the Society (p. 1302).

*Division Engineer, Public Service Commission for the First District, 23 Flatbush Ave., Brooklyn, N. Y.

quadrilaterals from which to calculate the coördinates of the Manhattan points, referred to the Brooklyn base as the axis, it was thought that any material error in the angular work could be detected, and this would give a measure of the error to be regarded as unavoidable.

Measuring the Base Line

The base line traverse was measured with a 50-ft., flat, steel-wire tape, provided with a spring-balance handle containing a level bubble, thermometer, and adjustment for temperature correction. It was marked with nicks at each end for use with plumb-bobs. The tape was tested for absolute length by comparison with a standard tape of known error, as determined by the Bureau of Standards at Washington. Measurements were made on cloudy days, or during early mornings in the shade, to secure uniform temperature conditions. The line was marked in advance every 50 ft., and paper pads, ruled with a longitudinal line, were weighted down at these points, so as to relieve the head chainman of the distraction of getting line from a transit. Each measurement was made by simultaneous plumbings at the ends of the tape, which was held level. The forward point was marked at the average of a number of trials. For each series of measurements a fresh sheet of the pad was used. With a tape of this kind the difficulty of steady and precise plumbing was such that no individual measurement could be depended on to less than 0.003 ft., or 1 in 17,000.

No doubt a better method consists in using a longer tape, supported at short intervals, with a tape-stretcher; and measuring directly, without plumbing, on portable stations, as was done later in connection with other tunnel surveys in New York. However, with care, it was found that the errors were not cumulative, and, in a distance of 2880 ft. measured in this way, the variation between the mean and the greatest extreme of several measurements was only about 1 in 100,000. The ends of the line measured on the docks were connected to the triangulation stations on the roofs in two different ways, in order to avoid repeating an error. The points on the copings were transferred to the dock level by casting down intersecting lines of sight from three transit set-ups. As a further check, an independent traverse, closing on the same points, was run by a different party in the marginal street back of the warehouses, and this gave a result agreeing with the dock traverse to 1 in 150,000.

Instrument Work

The triangulation sights were octagonal pine poles, 2¼ in. diameter and 8 ft. high, painted in alternate bands of red and white. These could be bisected readily, and gave no sensible difficulty from phase, because of the comparatively short range and the cloudy weather selected for instrumental work; but it would have been better practice to use higher targets with wide, flat vanes, set alternately at right angles.

The angles were read separately by two observers, with different instruments. These were ordinary engineers' transits, reading to 20 sec. on a 6¼-in. limb. The eight angles of a quadrilateral were measured separately by successive additions upon the limb. The entire angle at a station was also read, as a check on the sum of its components. To avoid bias, the angles were started at random near zero. Turnings were made, accumulating from left to right, until the sum became as nearly as practicable 360°, or its multiple. Reversing the telescope, and setting on the right-hand target, the same number of turns was made from right to left until the sum was diminished to near the original reading. Both verniers were read at the beginning, at the middle, at intermediate points, and at closing. In case an angle failed to close nearer than an average of 4 sec. to each turning, the result was discarded and the angle was read again.

When the third angle of any triangle of the system had been read, the angles were added, and if their sum varied from 180° by more than an average of 5 sec. for each angle, the three angles were read again. The quadrilaterals were tested in like manner. It was found necessary to read over only one triangle, and in this case the trouble was located at a station where the conditions for observing had been less favorable than elsewhere.

In comparing the observed angles, it was noted that the direct reading of an angle was generally greater (by 2 or 3 sec.) than its value as found by taking the difference between two angles; and that, at the end of an observation, the closing reading was nearly always greater than the first. As this pointed to a small persistent error, it was seen that it would have been a better program to measure each angle both directly and by its 360° complement, and to take the mean.

Computing and Checking the Triangulation

The set of observed angles of each quadrilateral was adjusted by the method of logarithmic residuals, based on the principle of least squares, according to Johnson, and using the rigid method of making the side equation correction. The angles read by each observer were adjusted separately. The corrections for spherical excess and reduction to sea-level were omitted as insignificant.

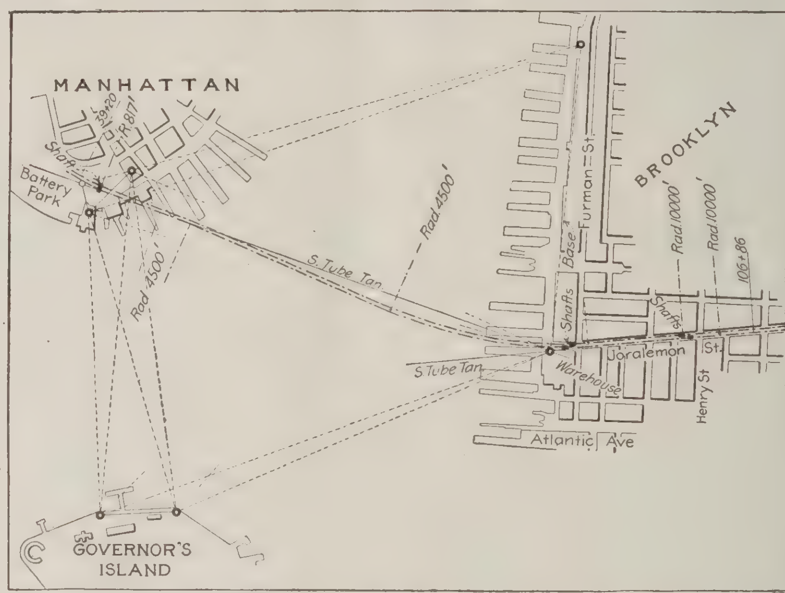


Fig. 1. Plan of Triangulation Survey for the East River Tunnel from the Battery (New York) to Brooklyn

The four quadrilaterals formed four pairs, each with a common triangle. These relations would give rise to additional equations of condition, and the simultaneous adjustment of all four quadrilaterals would be possible, theoretically. However, this was not attempted because the refinement would not pay for the effort, and because it was desired to compute each quadrilateral separately adjusted, so as to gain a practical idea of the effects of error in the angular work.

For the purpose of comparing results, the coördinates of the Manhattan and Governor's Island stations, referred to the Brooklyn base, were then computed for each of the four adjusted quadrilaterals of each observer. On plotting to full size it was found that for any point the various positions thus computed fell within the section of the target pole. It was seen that considerable time and labor would have been saved (and with sufficiently accurate results) by using any one quadrilateral, but the advantage of

learning in this way the probable extent of errors from all causes was thought to warrant the extra trouble.

The sides of the triangle formed by the two Manhattan triangulation stations and the point of known stationing in Battery Park were then measured, and the coördinates of the latter point were computed from those of the other two. The distance triangulated for was then determined. The computed length of the Governor's Island base (about 700 ft.) was found to agree with its original measured length within 0.016 ft., or much less than the probable angular error would account for.

The stationing of the Brooklyn intersection of the south tube tangents then being known, base-tape measurements were made from this point to the Brooklyn shafts. Stationing was transferred to the tunnel by plumbing in the shafts. All measurements, above and below ground, to determine stationing in the tubes, were made with the same kind of tape as that used for measuring the base, and in a similar manner. When the first headings were connected, the measured distance was found to be about 0.02 ft. short of that calculated. The discrepancy was somewhat more than had been expected, but may be adequately accounted for as combining the error in angular work with the error due to the difference in conditions, with the apparatus used, between taping in the tunnel and taping the base line on the surface. Its effect on the results of the surveys for alignment and grade, however, was very slight.

For establishing the Manhattan tangent alignment, there was no point on line in Battery Park, near the shaft, that was high enough to afford a sight to Brooklyn over the intervening ferry houses. For this purpose, two towers, about 35 ft. high, one on each tube line, were erected about 150 ft. west of the shaft. From these it was possible to look across the river over all obstructions and see targets on the warehouse roof in Brooklyn set on the Manhattan tube lines prolonged. The towers were built as triangulation towers usually are: with an interior tripod of three 8x8-in. timbers rigidly bolted together at the top and braced. This was inclosed within, but nowhere touching, a four-post tower braced on all sides and supporting a platform for the observer a little below the top of the tripod.

Plumbing the Shafts

Line was transferred to the tunnel in the following manner: A transit, mounted on a trivet, was set on the tower tripod on the tube center line, as plumbed up from a hub under the tripod by several reversals of another transit set on the center line a short distance away. The tower transit, fore-sighting on the Brooklyn target, set (by repeated plungings) a point on center line on the surface, about 10 ft. beyond the shaft. On this point a transit was set up, with its plumb-string in the mean position of the several settings; then, fore-sighting on the plumb-string of the tower transit, it aligned two plumb-wires suspended in the shaft.

Steel piano wire, 0.02 in. diameter, was used for this purpose. It was wound on brass reels 9 in. diameter. The reels were set, with their axes across the line, on stringers attached to the head-frame posts, high enough to permit sighting on the wire and to fore-sight by merely changing the focus. As the wire left the reel it ran over a small grooved wheel on a threaded axis, turned with a thumb-screw, by which slow lateral adjustment could be given. The wire was kept taut by a 20-lb. weight suspended in a pail of water at the bottom of the shaft.

The wires were shifted laterally until the vertical hair exactly bisected the plumb-string fore-sight and both plumb-wires. When this condition was reached, a transit set up in the tunnel below (as close to the wires as practicable) was shifted laterally until its vertical hair exactly bisected both wires. Then reversing, it threw the line forward, setting two or more plummet-lamps hung from verniers reading on graduated brass scales attached to the roof of the tunnel. Resetting on the wires, another set of readings was taken. Two more sets were taken in like manner with telescope reversed. The wires were then shifted and reset by the upper transit, and the previous operations were repeated for four more sets.

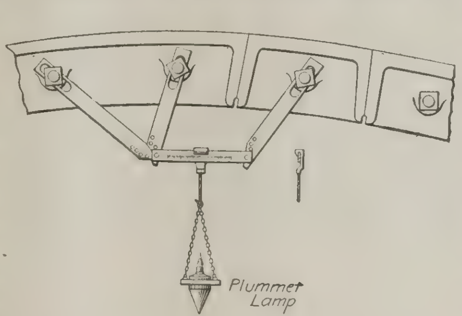

Fig. 2. Scale for Alignment of Tunnel

The whole of the foregoing operations was then repeated, after interchanging transits at top and bottom, turning the water pails containing the weights partly around, shifting the wires, examining them to see that they hung free, and interchanging the members of the party. This work of plumbing the lines down the shaft was usually done on Sundays, when the cages were not running.

The base between the wires was about 10 ft. at the Manhattan shaft and 15 ft. at the Brooklyn shafts, and in each case was as long as permitted by the width of the shaft. On account of the shorter base in Manhattan, and the extra operation there in transferring line, opportunity was taken, when the headings were afterward extended west from the shaft, to check the line by plumbing through a vertical 6-in. pipe sunk from the surface to the tunnel at a point on the center line of one of the tubes, about 130 ft. from the shaft.

Method of Aligning

The alignment scales were brass bars, 1 in. wide, ¼ in. thick, and 10 in. long, graduated to 0.01 ft. They were connected by three flat iron bars to the bolts of the tunnel lining at the roof (Fig. 2). The scales were read to 0.002 ft. by a sliding vernier from which a plummet-lamp was suspended.

The line established on the scales near the shaft, as the mean result of many days' droppings, was produced by repeated runs read on scales set at intervals of about 200 ft. These runs were made by different observers, and using different transits, until mean readings were well established on the advance scales. Where the tube was on a curve, the scales were placed on tangents as long as could be obtained, and usually near points of intersection. The angles at these points were carried forward by repeated turnings on the forward scales.

When it became necessary to carry the line through a lock, the transit was placed on a trivet on a timber wedged across the lock at the forward end, where it had the support of the bulkhead wall. It was then lined in with the last two scales, the forward one having been located as close as practicable to the lock, and a reading was taken on a paper scale set inside the lock over the outbord door. The lock was then taken in, and, before throwing the line ahead, the paper scale was read again to detect any possible movement due to change in pressure. No trouble was ever experienced on this account, however, and when the bulkheads were advanced the lines thus locked through checked quite satisfactorily with lines carried through in free air.

To assist in aligning a transit with two given points, a very useful device was furnished by the instrument maker. This consisted of two sliding plates, which were attached between the transit base and the tripod head or trivet, and permitted considerable range of lateral movement by a slow-motion screw.

Giving Level Points for Grade

Grade was established between the two sides of the river as follows: Level runs were made from the shafts on each side to benches under the Brooklyn Bridge on the river side of each tower, at which point the river is much narrower than at the tunnel line. Levels were set up on each side, and simultaneous reciprocal readings were taken a number of times. The instruments were then interchanged and the readings repeated. In this manner errors due to refraction, curvature, and imperfect adjustment were compensated.

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

In the conduct of a great industry like coal mining, which requires the services and time of nearly a million men in the United States alone, there must be all kinds of individuals to handle the diversified work in hand. It is necessary that thousands of humans labor in the dark depths mining and loading coal; other thousands oversee the manual work and direct the physical effort of the mass of workers along intelligent lines; a smaller number of men control expenditures and pass on the plans formulated to secure efficiency in operation. All of these people, whether workmen or officials, are directly connected with the production of coal, and are specified as being in the operating end of the business.

There are other lines of endeavor, however, that bear a direct relation to coal mining, and which are absolutely essential to the successful advance of the industry, although the effort put forth cannot be measured in tons of output. These latter workers are the teachers and thinkers who spend the greater part of their time in the compilation of facts and the manufacture of ideas for the operating end to test out. It's the old, old story of theory as related to practice, and the futility of any effort based on either one, without reference or attention to the other. If all the brains of our industry lay centered in the strong arms of the sturdy toilers who mine the coal, the business as a whole would soon reach a sorry pass. But on the other hand, if all the strength needed to get the fuel out of the ground was mental horsepower, the final outcome would be no less disastrous.

We have written a number of sketches of prominent men actively engaged in the production of coal, and it is about time that something is said concerning the teachers and thinkers who work just as diligently and as effectively for the good of the industry. Few men are more widely known to coal people than H. H. Stoek, who has devoted most of the working hours of his life to the mental betterment of the men engaged in the coal business.

After graduating from the High School in Washington, D. C., in 1883, Professor Stoek entered Lehigh University, South Bethlehem, Penn., graduating in 1887 with the degree B. S. in Mining. He spent the following year doing post graduate work, for which he received the degree E. M. (Engineer of Mines).

H. H. Stoek

During the summer of 1885, while yet a student, Professor Stoek acted as assistant in the Department of Mineralogy, at the National Museum in Washington. During the summer of 1887 he filled the position of Government Inspector of Dredging Work on the Thames River, Conn. From June 1888 to January 1890, he was assistant engineer for the Susquehanna Coal Company, Wilkes-Barre, Penn., being engaged in surveying, general underground and office work.

In January, 1890, H. H. Stoek accepted a position as Instructor in Mining, Metallurgy and Geology at Lehigh University. From September 1893 to January 1898, he acted as Assistant Professor of Mining and Metallurgy, Pennsylvania State College. During the vacation months, while teaching at Lehigh and Pennsylvania State College, much time was spent in personal investigations and professional work. Among other things, a report was made upon iron properties in western North Carolina.

From January 1898 to 1908, Professor Stoek served as editor of *Mines and Minerals*, Scranton, Penn. During this time he visited most of the mining regions of the United States, making a careful study of the coal mines in practically every district, together with visits to the metal mines of most districts, excepting those on the Pacific Coast. This work was done in the interest of his paper, and the results of his investigations in the different fields were published from time to time.

Professor Stoek's editorial experience has not been confined solely to his work for *Mines and Minerals* but has covered a broad field of activities, which included the editorship of the "Coal and Metal Miners' Pocketbook," Fulton's "Coke," "Examination Questions for Certificates of Competency in Mining," and Lake's "Prospecting for Gold and Silver," also a number of volumes on coal mining comprised in the complete course of the International Correspondence Schools.

He is author of the chapter on "The Economic History of Anthracite," which forms a part of "The Economic History of the United States," being gotten out by the Carnegie Institution of Washington, D. C., under the general editorship of E. W. Parker. "H. H." was also in charge of waste in mining anthracite for the United States Geological Survey, when the Bureau of Mines was created. His work along this line was never completed because of the change in administration when the Mining Bureau was formed.

During the time that he was engaged in editorial work, Professor Stoek gave a number of special lectures on mining at Cornell University, Pennsylvania State College, Sheffield Scientific School and the Brooklyn Polytechnic Institute. On leaving *Mines and Minerals* in 1909, he again took up educational work, having been appointed Professor of Mining Engineering at the University of Illinois.

Since locating in Illinois, "H. H." has taken an active part in the development of first-aid and mine-rescue work. He is a member of the Illinois Mines Investigation Commission; secretary of the Rescue Station Commission; member of the First Aid Committee of the National Red Cross, and was special representative of Governor Deneen at the American Mining Congress last year. He is also a past president of the Coal Mining Institute of America, and in addition to his present duties as Professor of Mining, is engaged in an extensive coöperative investigation of the coal-mining industry of Illinois, in connection with the State Geological Survey and the United States Bureau of Mines.

During the past two or three years, Illinois has made more rapid progress in the matter of first-aid and mine-rescue work than any other state in the Union, and much of this advance has been due to the well directed efforts of Prof. Stoek.

Correspondence suitable for the columns of Coal Age solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Entered as second-class matter, October 14, 1911, at the post office at New York, New York, under the act of March 3, 1879.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of Coal Age, we will print 8000 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.

This journal has a direct aim—a single purpose—which is to help advance the coal-mining industry. Its creed embodies the dissemination of knowledge and the free interchange of ideas among its readers, all of whom are invited to become regular contributors.

COAL AGE

The Hookworm

Every little while comes the suggestion that ankylostomiasis is likely to become chronic in American coal mines, as a result of the entire absence of sanitary precautions. There seems little danger of its general prevalence, however, until we begin to exploit coal beds much deeper than those which are worked at the present time.

We await with interest what the Bureau of Mines may have to say about the *ankylostoma duodenale,* the nematode which is colloquially known as the hookworm, or hairworm, and which is somewhat different from the hookworm of the South, though quite closely allied.

The Bureau and Marine Hospital Service of the United States have been investigating the matter, and state that "the hookworm has been found as a miners' disease in a number of different localities of the United States." "It is," the director of the bureau remarks, "important that the work of investigating the progress of the disease should be extended more rapidly, because of the fact that the health conditions, as well as the risk of accidents, may be influenced by conditions susceptible of easy improvement."

It is this extract from the report made to the President, which alone justifies the discussion of the disease in this coal journal, for the malady does not seem likely to menace the American coal worker, and should normally escape reference in these columns. The disease is the result of the ravages of a worm which infests the human intestines and feeds on the human blood. The female of the species lays some millions of eggs.

These eggs ungerminated pass out of the human body in the feces, being prevented from development by the internal heat of the digestive organs (96 deg. F.), and by the absence of air. The ova will not germinate at any temperature exceeding 86 deg. F., nor will they develop when they are excluded from the atmosphere.

According to a report made by Sir Cecil Hertslet to the British government, based apparently on observations by Dr. Herman, the ova of the ankylostoma may be transformed into worms if the temperature where the feces are deposited exceeds 57 or 59 deg., and is less than 86 deg. F.

Dr. Stiles, however, in the famous bulletin 10, issued by the Hygienic Laboratory, suggests that at the lower limit the action of germination is slow and feeble, for he says that: "At a temperature of 79 deg. F., the embryo may form and escape from the shell in 24 hours. Lower temperatures retard development, so that at 70 or 72 deg. F. the embryo may not escape for 36 to 40 hours." He has, however, nothing to say about the germination at such a low temperature as 57 or 59 deg. Fahrenheit.

A mine, therefore, which is warm is likely to favor the development of the germ. If, however, the mine is cooler and quite moist, it is probable that both coolness and moisture will destroy it. While yet an egg, or even in the first stage of its development, as a living worm, the growth of the ankylostoma is retarded by the presence of moisture; much water will actually kill the eggs. But in the second stage of its multiform life, it takes kindly to water, and the worms have been kept in that medium for 30 days by A. Looss, without loss of activity.

Hence, in a cool mine, where the fetal development is slow and the air moist enough to cause the feces to deform and flow, the environment for the germinating worm must be distinctly unfavorable, especially when the temperature lengthens the time of hatching, enough to permit the mass to deliquesce. And in a hot mine, like some of our deeper metal mines, dry as is an oven, the germ will be killed by the heat, and should it reach the second stage of development, it will be killed by drying up.

The danger is greatest, therefore, in mines of temperatures from 70 to 86 deg. F. The average drift mines are not usually so warm, unless they pass under unusually heavy cover. In several West

Virginia mines, even though steam is used in the intake to moisten the air, the heat of the workings does not anywhere exceed 59 deg., though the covering strata aggregate nearly 600 ft. But in shafts of the Middle West, temperatures rule high and records have been taken, showing 60 to 78 deg., and doubtless equally high temperatures may be found in the anthracite mines.

In these latter the disease may possibly take hold, but even there the risk is small, for it appears that the egg of the worm does not hatch out in the open air of England, Belgium, France or Germany, and temperatures there are as favorable as in the shafts of Illinois or northeastern Pennsylvania.

There the disease is present in the mines ready to spread to the surface. The eggs are continually coming to daylight, transported by a half dozen different media—water, coal, the clothes and bodies of the men and their feces, etc. Some of the habits, that of wearing clogs, should make the spread of the worm easy. Nevertheless, in northern Europe the ankylostoma is purely a miners' pest; it does not attack his family.

We can understand, perhaps, why the hookworm does not extend northward from the Carolinas, Georgia and Florida, because an exposure to 34 deg. F. for one or two days will destroy the ova. Consequently, the disease could only spread in the north through the mines, which it seemingly cannot invade. But in northern Europe, it already has made the mines its habitat. The workings act as winter incubators, and the whole of the out-of-doors will serve for hatcheries in the summer if the summer temperatures of those countries be favorable. That anemia, cachexia and pyrosis do not affect the outdoor workers of northern Europe must be because the conditions for incubation in those countries are not favorable enough that such incubation can generally take place even in the summer months.

From this fact we draw no little hope, confident that hookworm will not be a vocational disease of miners in any extended measure, but we still look forward with much interest to what will undoubtedly be the conservative statements of the Bureau and the Hospital Service. Our mines are getting deeper and therefore warmer, so perhaps this scourge is truly to be feared.

The Pittsburgh Rate Case Again

The coal operators have never before faced a more callous or stubborn attempt at usurping their rightful prerogatives than that exhibited in the stand taken by the railroads in the Pittsburgh-Lake rate case. While technically within the letter of the law, the skillful subterfuge by which the roads evaded complying with the manifest intent of the Commission's rulings, is so obvious as to warrant prompt and vigorous action by the government.

It is clearly evident that the carriers regard the efforts on the part of the coal industry to obtain some control over the markets as a presumption which they will oppose on every conceivable ground. The very magnitude of the case gives it a particular significance, also the fact that it will doubtless be quoted as a precedent in all future rulings of a like nature. For this reason the decision will be bitterly contested by the railroads.

Practically coincident with establishment of the new Pittsburgh rate, the carriers put in effect a lowered tariff on the West Virginia product which to all intent and purposes completely nullified the decision of the Commission. Thus the differential condemned by the Commission and that reëstablished by the railroads in lowering the rates from West Virginia were, respectively: Pocahontas and Tug River district, 33¼c. against 34c.; Thacker and Kenova district, 18¼c. against 19c.; Fairmont, 8¾c. against 12c. Not only were the findings of the Commission rendered void, but a still more pronounced differential against the Pittsburgh operators created.

That these machinations of the roads were premeditated and the way paved for their successful consummation is not to be questioned. Both the Norfolk & Western, and the Baltimore & Ohio, during the course of the original hearing, requested the Commission to sanction an increase in the rate prevailing at the time. This was apparently a mere sham since, after vigorously maintaining the necessity of such an advance. they not only declined to establish it, but the latter road went even further by making a reduction.

The Commission found, in its ruling in this case, that the carriers had established the then existing tariff "in order to let certain competing coal fields into the Lake trade," and when fixing the new differential said further:

> In arriving at this conclusion we are not unmindful of the fact that these rates may deprive the shippers from the Pocahontas and Thacker (Kenova) fields, along the line of the Norfolk & Western, of their present market.

It is thus clearly evident that the basic intent of the Commission's ruling was the establishment of a new differential. That they refrained from making this even greater may be ascribed partly to the testimony of the carrier's chief witness, who swore under oath that: "In his opinion, when that differential is fixed it will be observed until the lines in interest can get some permission from proper authorities for changing it." And partly to his statement that a conservative estimate of the tonnage that would be affected would be 60 million tons per annum, exclusive of that directly involved in the Boileau case.

If such testimony as this could be given any weight, the Commission displayed an entirely justifiable conservatism in the differential upon which they decided. But since subsequent developments have proved conclusively that this testimony is not to be relied upon, and the railroads have insolently ignored the decision of the Commission, it appears that the time has arrived when it should either justify its existence or be dissolved.

Under the Mines Act of Great Britain, the workmen are empowered from time to time to appoint two of their number, who are practical working miners, to inspect the mine. The persons so appointed must be allowed (accompanied by the manager or one or more officers of the company) to go to every part of the mine and inspect the shafts, levels, planes, working places, return airways, ventilating apparatus, old workings and machinery. Every facility must be afforded for the examination and a signed report of the result of the inspection has to be recorded in a book, kept at the mine for that purpose. Should the report state the existence or apprehended existence of any danger, the manager is required to cause a true copy of the same to be sent to the mine inspector of the district. This privilege is today being more generally taken advantage of by the men.

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Standards in Coal Washings

I was very much pleased to note the comments in the May 25 issue of COAL AGE, referring to my article in *Mines and Minerals,* on "Standardization in Coal Washing."

I hope I will not be misunderstood in this matter as it was not my object in publishing those data to make the claim that my method of determining washery efficiencies was the only one that could be employed. I have made a careful study of this subject for a number of years and have long felt the need of some method of actually determining the efficiency of a coal washery. I have often heard the term "efficiency" used in connection with coal washing but have never read anything that would indicate, nor have I been able to get others to state, in just what sense they used this term. In fact, I have never known anyone to state that a 65% or a 90% efficiency had been obtained, but in the use of the term, it is always referred to as a "high" or a "low efficiency."

There are several reasons why I feel that my method is a good one. One is that, by the use of my formulas, every item of a test can be checked and nothing assumed. This in my opinion would indicate that the method is along the proper lines at least. Another is that, as you mention, the separations are made in an exactly similar manner to that which must be employed in the actual washing of the coal. There may be some rare cases where the refuse matter is lighter than the good coal but in such cases the float would be considered as refuse and the sink as coal. My formulas could still be used in such cases by rearranging the terms to suit the conditions. Other rare cases might be found where the refuse material and coal were of the same specific gravity, but that is just the point I wish to emphasize as the valuable part that the float test plays in checking up the work done by any washery. For is it not true that, were such a difficulty met in the float tests, and a separation of the impurities from the coal impossible, it would also be impossible to obtain a separation on any form of washing machine, since they all depend upon a difference in the specific gravities to make their separation?

Some claim that in making float tests a number of gravities should be used so that the coal sample will be separated into good coal, bone coal, slate, rock, etc. I have done this same thing at times though I cannot see that such data have any great value. In washing coal, one first determines just how high a percentage of ash can be permitted for the particular proposition in hand. For instance, in a coking proposition where 14% ash is absolutely the limit for the coke, and experiment has shown that an 11% ash coal will produce 14% ash in the coke, there is no object in producing a washed coal of a lower ash content than 11%. Of course, if a 12% ash coke will sell better or for a higher price, and the loss by refuse in producing a lower ash washed coal does not amount to more than the increased profit of the 12% coke over the 14%, then a 12% coke should be made and the coal washed to suit. It is therefore seen that one must first determine the *limit* of ash content before anything else is done and everything therefore is based upon that figure.

What must be known is, how much bone coal can be thrown with the low ash coal and not raise the ash content of the washed coal above the limit placed upon it. For instance, if the low ash coal (say everything below 1.35 sp. gr.) has an ash content of 8%, and the bone coal 15%, and our limit is 11%, how much of the 15% ash product can be mixed with the 8% ash coal to produce a final product having an 11% ash content?

By separating out all of these different grades as mentioned, and recording their percentages and their ash contents, such data could be calculated. But it is easier and quicker to simply run a series of float tests for the raw coal as suggested in my article and in this way determine at once just what specific gravity bath will produce a float coal of the desired ash content. This, then, is what I term the "permissible bath" and is used for all tests on that coal, or the refuse and washed coal from it.

There is just one point upon which I have been a little in doubt and have as yet been unable to find any satisfactory solution. As stated before, a limit must be placed on the ash content for every separate proposition and as this limit would vary to a considerable extent, it might seem to make it impossible to compare the results of the work performed by different plants on exactly the same basis. Still, I find that this does not make a very great difference and in fact I have about come to the conclusion that it has no effect at all as the efficiencies in every case are based upon the comparison between the actual separation as obtained by washing, and the perfect separation as obtained by the float test. This, I find, seems to eliminate the apparent error as, for instance, a jig of one type producing 60% efficiency on one coal as against a 70% efficiency of another type of jig on another coal, the latter will also only produce about a 60% efficiency on the coal the other machine is working on.

There is another item to which I wish to call particular attention. I have found that very few engineers make float tests of the washed coal, the refuse only being tested. It is very important that such tests be made on the washed coal also, for if there be any pieces of refuse matter, particularly pieces of the very high ash slates, etc., present in the washed coal, they tend to raise the ash content much more rapidly than would a greater quantity of lower ash bone coal. In coking propositions they also have a very detrimental effect on the coke which is not produced by a larger amount of the bone coals, as they act as heat absorbers instead of creating any heat in themselves and will cause greater cross-fractures and fingering of the coke. It is therefore desirable that there be no incombustible pieces in the washed coal and that the float tests of the washed coal should be taken into account in determining the total efficiency. Also, whenever there is any sink obtained from the permissible bath test of the washed coal, it will be found that the percentage of washed coal is lower than it should be, as determined by the permissible bath test of the raw coal.

I do not think I need add anything further to that portion of my paper treating upon the subject of loss of "good coal" in the refuse, or as to what constitutes "good coal." That which I have just discussed regarding the mixing of as much bone coal as possible with the low ash coals covers this matter fully, for, most certainly, any coal, whether bone or low ash, which was floated on the permissible bath in the raw coal tests is "good coal."

I hope those interested in this subject, and who care to take up the discussion in the columns of your journal, will first study carefully all the data presented in my paper and consider it from all angles, as I have found it a matter which cannot be decided upon hurriedly. I am most certainly willing and glad to

change my views if anyone brings forth a better method or will show wherein I am wrong. I do not consider a plain statement all that is sufficient, but think the reasons should be given and, if possible, a better way suggested. I hope my paper may result in bringing out some ideas that will facilitate the adoption of a standard method of calculating washery efficiencies and make it possible for all engaged in this branch of engineering to understand one another more clearly. The standardization of the form of report would also, I feel sure, greatly assist the coal-company officials to understand more thoroughly the work being done by their washeries and make it possible to more accurately compare these results with those of other companies.

G. R. DELAMATER,
Consulting Engineer.
2357 Cherry St., Denver, Colo.

Purification of Feed Water

I have noticed the following statements occurring in recent issues of COAL AGE; namely, in the last paragraph, p. 804, Mar. 30, " . . . . and the sulphates are precipitated by soda ash"; and again, in the second paragraph, p. 1002, May 11, "Moreover, the soda-ash solution, which removes the sulphates, chlorides, etc."

The author of these statements makes it appear that the sulphuric acid of the sulphates in the water treated, is precipitated by the soda ash as sodium sulphate, and thus readily removed from the feed water. My experience in the soda-ash treatment of mine water fails to corroborate these statements of your correspondent. In treating a permanent hard water with soda ash, the reaction may be expressed by the following simple equation:

$$RSO_4 + Na_2CO_3 = RCO_3 + Na_2SO_4$$

in which "R" represents the basic metals combined with acid. The resulting salts are carbonates of "R" and sulphate of sodium. The carbonates are precipitated and can be easily removed from the water by settlement or filtration; while Na_2SO_4 being a soluble salt, is not removed from the water by these methods. The soda-ash treatment simply causes a transformation of the sulphates of all other metals into sodium sulphate. The advantage in the process lies in the fact that sodium sulphate is easily soluble in water and does not form scale in the boiler. The hard scales formed on the plates and tubes of boilers consist chiefly of sulphate of lime, etc., which adhere very firmly to the boiler plates. The formation of such material in a boiler is detrimental to the economic operation of a plant, since it is a poor conductor of heat; and the rate of combustion must be increased, which causes overheating of the plates and tubes of the boilers.

Wilkes-Barre, Penn. H. H. L.

[The sulphuric acid existing as sulphates in mine water is best removed by treating the feed water with barium hydrate, $Ba(OH)_2$; or limewater (slaked lime) $Ca(OH)_2$; and the resulting barium or calcium sulphate is precipitated with the basic hydrates formed.—EDITOR.]

A Mine Fire Incident

The recent discussion on mine fires in COAL AGE calls to mind an incident that is of value, as showing the need of greater intelligence and experience on the part of mine officials.

At the close of the day's work, a miner fired a shot that presumably started a fire in room No. 19 off the 4th left-butt entry. The room was a double room, having two necks or openings, with a road on each side of the room, and was driven 175 ft., on a 2-per-cent. upgrade. There was a crosscut half way up, between rooms 18 and 19, and another on the opposite side, between rooms 19 and 20, about 60 or 70 ft. from the face of room 19 and in the face of room 20. The accompanying diagram or plan shows the position of the three rooms, Nos. 18, 19 and 20; the location of the fire marked *F*, at the face of room 19; direction of the air currents in the entries and rooms, indicated by the arrows; etc.

PLAN OF ROOMS, SHOWING LOCATION OF FIRE

The fire was not discovered until the fireboss, making his rounds the next morning, entered the 4th-left heading and found it so filled with smoke that he could not proceed. He retired at once to the 3d-left air course or entry and made his way through a manhole marked *H* in a nearby brattice, to the 4th-left heading. Seeing smoke coming out of room 19, he went up room 20, and looking through the crosscut at the face, discovered the seat of the fire, which was evidently beyond his control. Returning to the surface, a mile or more, he notified the mine foreman, who, with the mine engineer, went in at once, reaching the fire about 6 a.m.

After a brief consultation, they decided to flood room 19 by building a dam in the crosscut between 19 and 20, and another in the neck of room 19. This was Friday morning. Except for two or three entries on the return of the fire, the mine worked all day as usual. The foreman ordered cement and other material taken in to the fire, intending to build the dams of concrete made of cement and broken coal, egg and nut size. The work of getting the material in readiness took all day, and at six o'clock Friday evening, nothing had been accomplished in extinguishing the fire.

The heat thrown out by the burning coal was now intense, which caused a big cave at the face of room 19. For several days past, the miners in this room had thrown back their surplus coal in a pile. This coal was burning under the fallen roof, which covered it about 5 or 6 ft. deep. The mine foreman seemed at his wit's end to know what to do. The engineer and about a dozen men were there waiting for some one to tell them what to do.

Finally, the foreman sent for an old, experienced miner, who had worked before in putting out fires. This man came and looked at the fire and asked the foreman what his plan was for putting it out. The miner told the foreman at once he could not "drown out" the fire as he expected, because of the crosscuts beween rooms 18 and 19. The plan was, therefore, promptly abandoned, and the miner, being given charge, soon had things moving.

Men were now set to work propping the fallen roof. A brattice was carried up the neck of room 19, as far as possible, hoping to reach the crosscut, and thus form a return for the air current, to prevent it from passing over the fire. This proved successful and a canvas was hung then in the heading, between rooms 19 and 20, to throw the air up room 20, where it would return through the crosscut to the road in 19. This gave the men a fighting chance, enabling them to approach sufficiently close to the fire to do effective work. Soon a good stream of water was playing on the fire. Men relieved each other every 20 or 30 min. Progress was slow but sure. The fire was fought inch by inch till Saturday noon, when it was under control, and by Monday morning the fire was a thing of the past.

Republic, Ala. G. T. M.

H. B. Dixon has shown that an explosion is impossible in an absolutely dry atmosphere, and that mixtures of air and explosive gases require 5 per cent. of water vapor to produce the most violent effects.

Inquiries of General Interest

Questions are not answered unless accompanied by the name and address of the inquirer. This page is for you when stuck—use it

Squeeze in a 3-ft. Seam of Hard Bituminous Coal

I would like to obtain some information on the best method of working a 3-ft. seam of very hard coal, underlaid with from 6 to 14 in. of soft fireclay, which runs into a hard muck or clod. The cover overlying the coal varies from 40 to 300 ft. in thickness. Immediately above the coal is a hard slate overlaid with sandstone forming a hard cover that is difficult to break.

We are using the double-entry system. The rooms are driven as double rooms, having two necks to each room. There is a 20-ft. stump left between each neck or opening. The mine is an old one, having lots of worked-out territory. I wish to know if there is any way of stopping a squeeze in this mine when once started. I will be glad to give any further information if desired.

J. S. Freeman.

Corona, Ala.

A hard roof and soft bottom in coal mining are the most difficult conditions with which the miner must contend. A strong roof that does not break is a great temptation to drive wide rooms and the pillars left between them are often too weak to support the great weight thrown upon them by the extraction of the coal. To mine a seam of coal successfully, it is necessary to adopt and maintain a system of mining in accordance with the conditions as they exist. Practical experience in the district is always the best guide in determining the safe width of opening and the required thickness of pillars in room work.

In this case, assume the room necks are each 10 ft. wide, and the stumps between the necks being 20 ft. wide makes the clear width of the room 40 ft. For a hard bituminous coal 3 ft. thick, the strength of the pillars (tons per square foot) may be taken as, approximately,

$$S = 40\sqrt{\frac{w}{t}} = 40\sqrt{\frac{w}{3}}$$

The average weight of the strata is 160 lb. per cu.ft., which for a maximum depth of 300 ft. gives a roof pressure of

$$\frac{300 \times 160}{2000} = 24 \textit{ tons per sq.ft.}$$

By the taking out of the coal in the rooms, however, the pressure per square foot due to the weight resting on the pillars is increased in the ratio $\frac{w+o}{w}$ which makes the actual pressure on the pillars $24\ \frac{w+o}{w}$ tons per sq.ft.

The minimum width of pillar is then found by equating this value for the pressure on the pillars with the value for the strength of the pillars, S, found above; thus,

$$40\sqrt{\frac{w}{3}} = 24\,\frac{w+o}{w}$$

But, since $o = 40$ ft., we have, by reducing,

$$5\sqrt{\frac{w}{3}} = 3\,\frac{w+40}{w}$$

and

$$w = 1.08\left(\frac{w+40}{w}\right)^2$$

The value of w, in this equation, can only be found by trial. For example, try $w = 20$; then

$$\frac{w+40}{w} = \frac{20+40}{20} = 3$$

which, substituted in the last equation, gives

$$w = 1.08 \times 3^2 = 9.72$$

This being lower than the assumed value shows the true value of w is between 9.72 and 20. Therefore, try $w = 15$, then

$$\frac{w+40}{w} = \frac{15+40}{15} = \frac{11}{3}$$

and, again, substituting this value in the above equation, we have

$$w = 1.08\left(\frac{11}{3}\right)^2 = 14.5$$

The true value is therefore between 14.5 and 15; or, say the required width of pillar is 15 ft.

In this case, if *all* the entry stumps are 20 ft. wide, the room necks being 10 ft. wide, are driven on 30-ft. centers. This makes the width of the rooms 40 ft. and the width of pillars between the rooms 20 ft., which would certainly be ample, in this case.

If these assumptions are correct, the trouble from squeeze, mentioned by our correspondent, can only be the result of maintaining too large an open or abandoned area. The method employed is a good one. The hard roof would not permit longwall work, which but for this fact would be the plan to adopt.

Assuming the squeeze is under way, having obtained a good start, no amount of timbering will control or prevent its steady advance. The weight of the overburden is bound to travel forward until it meets a sufficient resistance for its support. A careful study of the mine map, on which should be marked exactly the affected area and the extent of the workings, will suggest the best plan to adopt in order to arrest or control the squeeze.

The plan adopted after studying the map, should consider: 1. The withdrawal of all standing timber in abandoned places. 2. A systematic drawing back of any room pillars that will divert or arrest the progress of the traveling weight. Experience is required to determine this. 3. It will be necessary to adopt means to break the roof in many places, by placing shots at suitable points in the roof. The effect of this plan will be to settle the weight on a solid bearing.

In this reply, we do not consider preventive measures, but have only outlined a method for the arrest of a squeeze already in progress. In this connection, the reply to the inquiry entitled "Methods To Be Adopted To Avoid Squeeze," Coal Age, Mar. 9, p. 719, will be of interest.

Early Coal Cutting Machinery

Can you tell me something about the early coal-cutting machines and the nature of their operations?

Du Bois, Penn. Mining Engineer.

Little seems to be known and to be on record relative to the early advances in the use of coal-cutting machines for undermining coal. The first patent appears to have been taken out in 1761 by Michael Menzies. He proposed to transmit power from an engine at the surface through a series of reach rods and chains passing over pulleys to a machine carrying a heavy pick, which was to undercut the coal. To drive these reach rods he proposed to use a "fire engine, a water miln, a wind miln, or a horse gin." By a fire engine he doubtless meant what we would now call a steam engine.

In the century following Menzies' invention more than a hundred patents were taken out having the same object. In one of the Lancashire collieries in 1847 a machine was erected by W. Story, of Gateshead. About that time or a little later the purely experimental stages of the history of "the iron man" may be said to end and the more practical stages begin.

First Machines Imitated the Miner

Fig. 1 shows an early form of coal-cutting machine. The illustration is

taken from Knight's American Mechanical Dictionary, Vol. 1, pages 580-581, published in 1877. Like many early illustrations it is in perspective and there is some difficulty in understanding the purpose and character of some of the parts illustrated. Consequently the reader will only be able to form a general estimate of the methods adopted for the effecting of results.

We quote the description verbatim from the aforesaid dictionary, in order to preserve certain quaint expressions and to illustrate some of the unreliable hopes which the early inventors held or desired to inspire in others:

"One form of the coal-cutting machine has an engine with a reciprocating piston driving a massive steel pick in any desired direction and at a very material saving in hewing or kirving. The motor-power is highly compressed air, condensed by the steam engine at the mouth of the pit and this elastic air is conveyed by slender pipes down the shaft and along the mines to the breast where the coal is being worked.

"The compressed air is pumped by the steam engine into a receiver at the pithead during the otherwise idle hours or by its surplus power when drawing up the coal or pumping out the water from the mine and is condensed to a tension of forty to fifty pounds to the square inch.

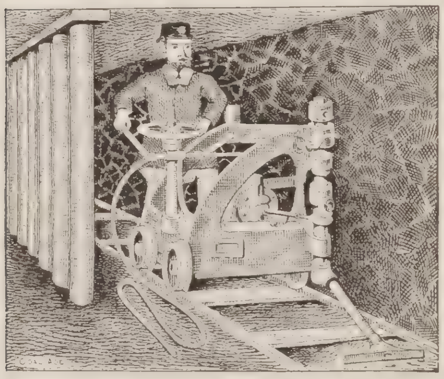

Fig. 1. An Early Coal Cutter

Air Released Is Expected to Ventilate Workings

"It is conducted in metallic pipes 4½ in. in diameter down to the bottom of the shaft and thence in pipes of smaller diameter to the workings, tubes of 1 or 1¼ inch caliber bringing it to the cylinder of the machine. This compressed air, when set free at each alternating stroke of the piston, imparts to the adjacent portions of the mine a pure dry, cool atmosphere, from a well known law of all air and gases that when expanded under relaxation of pressure they are relatively cool.

"The machine is supported by a cast metal frame of great solidity, and is of a size and weight proportioned to the coal to be cut. It is constructed to give the blow of the pick, either by the pull or push of the piston. The engine has an oscillating cylinder which has the merit of combining compactness of shape with but little complication of working parts.

"The machine rests upon flanged wheels and is propelled either backward or forward by a wheel and screw on a ratchet and pinion attached to one side of the engine. On the opposite side is a valve screw for regulating by hand the access of air to the engine. When working, the man seated upon the little stool in the rear of it moves the ratchet-screw connected with the gearing of the under-carriage, and thereby propels the whole machine along the little railway or tram laid parallel to the front of the coal seam, a small distance equal to the longitudinal nip or bite of the pick.

Machine is Required to Traverse Breast Thrice

"One machine, working 90 blows of the pick per min., discharges, of condensed air, about 100 cu.ft. per min., which immediately becomes 300 cu.ft. of cold air at the normal density and each machine is competent to supply from 12 to 15 per cent. of the ventilation required at the heading; the air being perfectly fresh, pure and cool and afforded precisely at the localities where the workmen are most in need of such atmosphere. When working at 120 picks per minute, the machine cuts an inch at each stroke 20 inches deep, 2½ inches wide; a second traverse deepens it to 30 inches and a third to 36 inches."

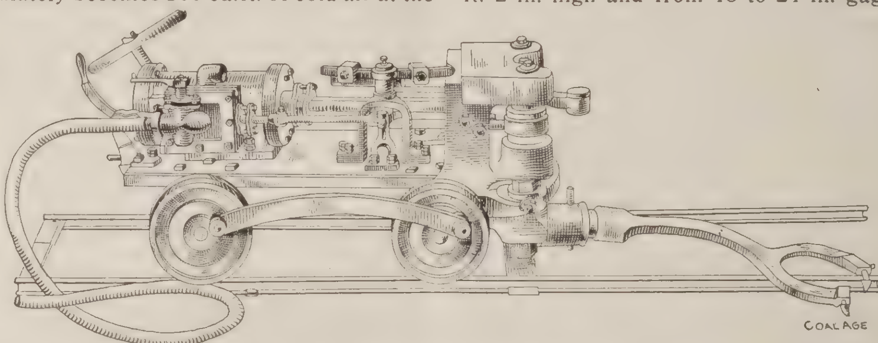

Fig. 2. The William Firth Side-striking Cutter

Firth's Machine Crosses Face But Once

In Fig. 2 is shown Wm. Firth's coal-cutting machine. He was a native of Sheffield, England. Like the preceding coal cutter, it appears to have been run in front of the face or breast of coal on a pair of rails and to cut on the side instead of on the end as with our modern punchers. Like all the successful early machines, it was operated by compressed air. At the rear end was placed a horizontal cylinder in which a piston reciprocated, the rod of which extended forward and operated a pair of bell cranks pivoted on two revolving spindles in the front of the machine.

These bell cranks each terminated in a socket provided for the insertion of a heavy pick. Each pick had two points, but instead of these being at either end of a straight bar, they were disposed on the end of what resembled the claw of a lobster, so that both could strike on the same coal face. They are so set, however, that one is cutting near the front of the cut and the other near the rear. Thus by one motion of the machine past the face, it is possible to cut to the full depth of 36 inches. It is clear that as the machine had two bell cranks and two revolving spindles it was possible to work the pick from either side, that is, either right or left handed.

Provisions for Moving Along Face

As in the machine previously illustrated, it was thought necessary to provide a miter wheel, shown at the back, for its propulsion in front of the face, and further in order to aid its progress, the four wheels were coupled in pairs on either side of the machine. The cutter was usually made about 4 ft. in length, 2 ft. 2 in. high and from 18 to 24 in. gage, and weighed about 1680 lb. It made about 60 to 90 strokes per min. and so cut from 10 to 20 yd. for a depth of 3 ft. in every hour; even at the lower rate of working, the machine cut 60 yd. in every shift of 6 hr., and the work was considered equivalent to that of 12 average men. The cut thus made was much similar to that made now by a chain machine, being 2 or 3 in. deep at the face and finishing to 1½ in. deep at the back.

Before the last machine was introduced a form of chain-cutting machine had been in use, invented by William Peace, in the Wigan district. This chain-cutter frame did not enter the coal by a sumping cut, as do our machines today. It was pivoted in such manner that it could be turned toward the face at an angle and when once it had made a quadrant cut in the coal it could be worked forward on the short-wall principle. Winstanley and Barker later invented a disk cutting machine; in working, this machine also made the first cut by the use of a swivel arrangement. The disc could be thrown around so as to be along the line of the track when making a sumping cut.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

Interesting Questions

(Answered by Request)

Factors of Efficient Ventilation

Ques.—What are the chief factors necessary to secure efficient ventilation in mines?

Ans.—There are three chief factors that are essential for the efficient ventilation of every mine. 1. A sufficient quantity of air must be conducted into the mine to comply with the requirements of the state mining law. 2. The volume of air passing into the mine must be divided and distributed to the several districts of the mine in proportion to their several requirements. 3. All of the air entering the mine must be conducted to the working face by means of substantial stoppings, air-tight doors, air bridges, brattices, etc. It is important that the air current should be made to sweep all void or abandoned places and falls, with a velocity sufficient to carry away any gases that would otherwise accumulate at these points.

Water Gage *re* Horsepower

Ques.—If 10 hp. is producing a circulation of 60,000 cu.ft. of air, in a certain mine; what is the water gage?

Ans.—

$$H = \frac{Qp}{33{,}000};\ \text{and}\ p = \frac{33{,}000\,H}{Q}$$

Therefore, for the water gage, in this case, we have,

$$w.g. = \frac{p}{5.2} = \frac{33{,}000 \times 10}{5.2 \times 60{,}000} = 1.058\ in.$$

Ques.—If 10 hp. produces a certain water gage, in a given mine; what water gage will 25 hp. produce, in the same mine, under the same conditions?

Ans.—For the same conditions in the mine, the water gage varies as the square of the quantity of air in circulation, and the power varies as the cube of that quantity. Hence, for the same conditions in the mine, the square root of the water gage and the cube root of the power each vary as the quantity; or they vary alike, the one as the other.

In other words, the square root of the water-gage ratio is equal to the cube root of the power ratio. The question does not give the original water gage; and, for this reason, it is only possible to find in what ratio the increase of power, from 10 to 25 hp., will increase the water gage. Thus,

$$\sqrt{\frac{(w.g.)_2}{(w.g.)_1}} = \sqrt[3]{\frac{25}{10}} = \sqrt[3]{2.5} = 1.357$$

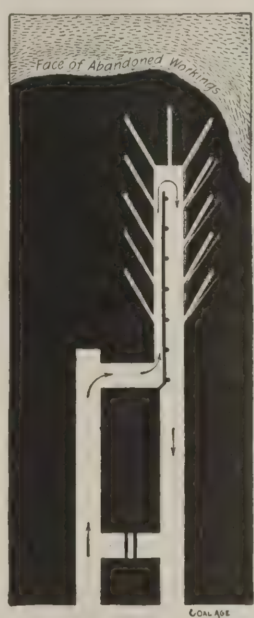
$$\frac{(w.g.)_2}{(w.g.)_1} = (1.357)^2 = 1.84$$

That is to say, increasing the power from 10 hp. to 25 hp. will increase the water gage 1.84 times.

Precautions Approaching Abandoned Workings

Ques. — Explain what precautions should be taken when approaching abandoned workings that may contain dangerous quantities of water or gas.

Ans.—In this case, no reliance should be placed on the mine maps although these may be made from accurate surveys. A slight error in the map or the survey might prove fatal. Only a single heading should be driven, not over 12 ft. wide. This must be ventilated by erecting a brattice to conduct the air forward to the face of the heading, as shown in the accompanying figure.



Heading Approaching Abandoned Workings

A borehole should be kept at least 20 ft. in advance of the face of the heading and flank holes should be drilled, at regular intervals, not more than 5 or 6 yd. apart, on each side of the entry. These flank holes should make an angle of about 30 deg. with the center line of the heading, as shown in the figure.

A sharp lookout should be kept for the first signs of water or gas. Plugs should be kept in readiness to stop the hole if it should suddenly break through into the old workings. Safety lamps, only, should be used. The heading should be well timbered.

Outbursts Of Gas

Ques.—What are the causes of sudden outbursts of gas when mining coal? How are they manifested and what precautions should be adopted in mines subject to such occurrences?

Ans.—Sudden outbursts of gas frequently occur in gaseous mines and are the result of the accumulation of gas under pressure, in pockets or foliations of the strata. As mining proceeds the strength of the walls or confining strata is insufficient to resist the great pressure of the gas, which finally bursts its bonds, throwing down tons of coal or roof in its effort to get free.

Outbursts are often heralded or their approach manifested by severe "poundings" or "knockings," which are sometimes heard for days in advance of the occurrence.

When mining under these conditions the precaution should be taken to sink large boreholes, from the surface, ahead of the workings, for the purpose of draining off the gas from the area soon to be worked. Holes are also bored in the face and ribs of entries to relieve the pressure of the gas on the coal. When the gas occurs in the roof or floor, holes are likewise put up in the roof or down in the floor of the seam, with good effect. Rooms and headings are driven less wide and are securely timbered as experience dictates.

Furnace or Fan Preferred

Ques.—When and under what circumstances are furnaces to be preferred to fans for ventilating purposes?

Ans.—Although a fan is always more reliable as a mine ventilator and requires less attention, in its daily operation, there are still some who prefer a furnace. The use of the furnace, however, should be restricted to the ventilation of small mines having shafts not less than 75 to 100 yd. deep, and producing no gas. Even then it is more economical and advantageous in many ways to replace the furnace with a good fan as early as the development of the mine will warrant making the change. In a nongaseous mine where the seam lies very deep, say 250 yd. below the surface the furnace is an efficient means of ventilation.

Sociological Department

For the Betterment of Living Conditions in Mining Communities

Navigation Co.'s Underground Hospital

The rescue and first-aid work in the anthracite region has the proper spirit. It is fostered and financed by the operating companies, but there is no question but what the men are interested and coöperating, and are willing to contribute to its development and support.

The fine underground hospital we illustrate here and on our front cover confirms this fact. The Lehigh Coal & Navigation Co. built the hospital, but the men spent $150 in the furnishing of it. It is situated 980 ft. below the surface in No. 8 shaft of the Coaldale colliery, near Lansford, Penn., and is excavated in the solid rock of one of the tunnels.

The upper illustration on the cover shows the outside view of the hospital. It is substantially built of concrete, and the approach is neatly paved with cement. The lower illustration is an interior view, the group consisting of the following, reading from right to left: Evan G. Evans, general foreman; James Harrington Young, company physician; Isaac M. Davis, mine inspector of the 17th anthracite district, and William E. Stickler, assistant mine foreman.

A Comparatively Germ-proof Room

The floor is covered with inlaid linoleum, the walls with Sanitas oilcloth paper and the ceiling with pale blue Sanitas paper. It is easy, therefore, to keep the room reasonably germ-free. The lighting is provided by 24 electric lights, strung along the vaulting line of the room and pendant from a chandelier in the center. The shelves alongside the medicine cabinet are of glass, supported by nickeled brackets. A stool and two couches with drop heads, all leather covered, are provided for the use of patients. There is also a Morris chair. The walls are hung with five Red Cross charts, showing the various parts of the human body. Set in the base of the couch on the left is a drawer, in which splints are kept.

Interior of Underground Hospital, Lehigh Coal and Navigation Co.

The illustration on this page shows the electric radiator and a copper boiler for preparing hot water. To the right are a porcelain washstand and sanitary bucket. The shelf above the washstand is of ¼-in. plate glass, with nickeled brackets, and is provided with absorbent cotton, witch-hazel, sweet spirits of ammonia, liquid soap, cocaine and peroxide of hydrogen. Below will be noted the hair clippers and shears for removing hair near scalp wounds, also bandage shears and large nickel tweezers for removing splinters.

Stretchers and Blankets

To those who have seen stretchers and blankets laid on the tipple rafters, or in malodorous sheds, the little stretcher closet in the left corner of the room will be of pleasing interest. Even this closet is lined with Sanitas paper. The blankets are hung from nickeled holders, shown on the left-hand side of the illustration. In this manner they are aired and better fitted for use than if rolled up and put in some dark corner.

The man administering the spirits of ammonia is John F. Boyle, the captain of the first-aid team at the Pittsburg meet. Seated in the chair is Harry Lewis, who furnished the information from which this article is prepared. Care is taken to produce a circulation of air through the room. A register 8x12 in. is set on the left of the door. This admits air to the room near the floor. A register situated near the springing line of the ceiling is connected with the return, and by means of this the air escapes.

This hospital certainly does credit to the "Old Company," and the men in shaft No. 8. The latter aver that from one end of the anthracite region to the other there is not to be found a better equipped hospital.

The Davy Lamp

The following is an interesting excerpt from a letter written in 1815 by Sir Humphrey Davy to Dr. Gray and the Rev. J. Hodgin: "Atmospheric air, when rendered impure by the combustion of a candle, but in which the candle will still burn, will not explode the gas from the mines. When a lamp or candle is made to burn in a close vessel, having apertures above and below, an explosive mixture of gas admitted merely enlarges the light, and gradually extinguishes it without explosion. Again, the gas mixed in any proportion with common air will not explode in small tubes, the diameter of which is less than one-eighth inch, or even a larger tube, if there is a mechanical force urging the gas through the tube. . . I have never received so much pleasure from the result of any of my chemical labors, for I trust the cause of humanity will gain something by them."

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

The Interstate Commerce Commission has made an important award in the case of Meeker & Co. vs. the Lehigh Valley R.R. Co. This is an application of the decision arrived at some time ago on the general merits of the case. The Commission now says:

In our original report we found that the rates charged the complainant for the transportation of anthracite coal from the Wyoming region in Pennsylvania to Perth Amboy, N. J., during the period from Nov. 1, 1900, to Aug. 1, 1901, were unjustly discriminatory and in violation of Section 2 of the act, to the extent that they exceeded the rates contemporaneously charged the Lehigh Valley Coal Co. under the contract then in effect between that company and defendant; and we further found that the rates in effect from Aug. 1, 1901, to July 17, 1907, were unreasonable to the extent that they exceeded rates of $1.40 per gross ton on prepared sizes, $1.30 on pea, and $1.15 on buckwheat.

On the basis of its conclusions in the former report and upon consideration of the evidence adduced at the hearing upon the question of reparation, the commission now finds that the complainant suffered damage to the extent of $11,009.33 during 1900 and 1901 and to the extent of $58,236.45 from 1901 to 1907. The complainant is therefore awarded the above amounts together with accrued interest, making a total of approximately $100,000.

Privately Owned Coal Depots for the Panama Canal

The coal question has figured considerably during the past in the hearings before the Senate Committee on Interoceanic Canals, which is now working on a revision of the canal bill passed by the House, for submission to the Senate. The committee has been strongly urged to permit the establishment of private depots in the Canal zone for the sale of coal, on a commercial basis. There is evident a considerable disposition to permit the establishment of such depots, but none to abandon the idea of the governmental sale of coal, or to limit the government to the supplying of naval and other ships belonging to the public. Whatever liberty is granted to the private individuals who wish to sell coal in the Canal zone, will be given with the understanding that the government is to continue to compete in furnishing this material.

Facts and figures have also been laid before the committee with reference to the probable effect of the trade in coal on the development of coastwise business for American ships. B. H. Baker, of Baltimore, asserted that if railroad-owned ships could be prohibited from going through the canal, there would be a great growth of coastwise business, making a demand for coal which would move, he claimed, in large quantities from the terminus of the Virginian Railway to the eastern gateway of the canal. This coal, he asserted further, would move in American vessels. This was presented as an additional argument against allowing railroad-owned ships, specifically those of the Pacific Mail Steamship Co., to go through the waterway.

Alabama

Birmingham—A meeting of the merger committee, in charge of the proposed consolidation of the Alabama Coal & Iron Co. and the Southern Iron Co., was held in New York, May 23. It was expected that some decisive step would then be taken, but so far no definite announcement has been made.

Coal dealers and operators from Tennessee, Alabama, Georgia, Mississippi and Louisiana met in conference here recently in an effort to reach a better mutual understanding on a number of matters affecting the trade. The questions of car-load weights and points of weighing were discussed.

Montgomery—A proposed ordinance, prohibiting the use of any coal other than anthracite within the city limits, is meeting with determined opposition on the part of local coal men and large consumers.

Colorado

Denver—At the Leyden coal mine, a Moffat property, lying 17 miles from Denver on the line of the tramway, the shafts have been lined with concrete and the whole mine made as nearly fireproof as possible. This work has been done at an expense of some $300,000 and was undertaken largely because of a disastrous fire two years ago in which 10 men lost their lives. The output of the mine is now 500 tons a day and will be increased to 1000 tons.

The Denver & Rio Grande R.R. and the Colorado & Southern Ry. have been ordered by the Interstate Commerce Commission to file before July 20, regulations to govern the ratings of coal mines on their lines in Huerfano and Las Animas Counties, and to provide for an equitable distribution of coal cars. The order was made on complaint of the Colorado Coal Traffic Association, members of which alleged the roads unjustly discriminated against certain coal operators.

Illinois

Hillsboro—Options on 1400 acres of coal land near Donnellson were recently transferred to Frank P. Blair, of Chicago, president of the Shoal Creek Coal Co., and it is understood that these options will be taken up by June 1. It is not known as yet just what the intentions of the Shoal Creek company are with regard to this property.

The Hillsboro Coal Co. is securing options on about 2000 acres of coal land in the vicinity of Fillmore. It is understood that the coal is to be held for development sometime in the future and that a mine will be opened, probably near Fillmore.

Benld—As a result of the riot at Benld recently, the coal operators of the fifth and ninth Illinois districts have named a committee to meet with representatives of the labor organizations to demand the establishment of a state constabulary.

Springfield—Initial steps have been taken in the transfer of the Barclay Coal Co.'s plant to a new corporation to be composed of prominent Springfield men. The new corporation will take over all leases held by the Barclay company.

Marissa—A thousand tons of coal, stored at the Advance mine of the Egyptian Coal & Mining Co., caught fire recently from spontaneous combustion, and after several days' labor the fire was checked, but it is estimated that 300 tons of the coal was consumed. The coal was stored close to the tipple, and only by strenuous work was the plant saved from destruction.

Streator—The new agreement between Illinois coal operators and miners was signed May 17, but the settlement has had little bearing on the reopening of the mines, a great number of which remain closed down, owing to dullness of the market. A revival of trade is expected if the Indiana miners continue to hold out against the proposed agreement in that state.

Indiana

Terre Haute—Acceptance of a tentative agreement for a two-year contract, and reference of the weekly pay question to the miners for a referendum vote, ended, on May 24, the stormiest joint conference in the history of Indiana miners and operators. The subcommittee reported to the special meeting of the joint conference that an agreement had been reached on all matters, except the contention of the miners for a weekly pay. It was decided to leave the question to a referendum vote. For the third time within a week, the wage-scale committee reported back to the joint conference its inability to reach an agreement, or even a basis for a settlement. John P. White, international president, made a forcible speech, explaining in detail his position in relation to the Indiana mine workers' demand for the weekly pay, and explained to the miners' delegates that the vote meant either a return to work without the weekly pay and with the other concessions granted, or a strike. A vote was ordered in all the locals of the district for May 27, to decide this question finally. If the miners vote to accept the wage agreement without this provision, the mines will resume work June 3.

The miners in many localities feel so strongly on the subject of a weekly pay and the radical element among them has wrought the men to such a pitch that they recently burned in effigy President White and other officers of the national union, who are urging them to accept an agreement which provides for a semi-monthly pay, as at present. If the referendum vote fails to ratify the proposed agreement, a strike will be in force in Indiana.

Vincennes—The Knox Coal Co., of Bicknell, on May 24, sold its mine and all holdings near Bicknell to the Worth-Huskey Coal Co., of Chicago, for $50,000.

Linton—The Forschner Coal Co. has purchased the Sponsler mine from the United Fourth Vein Coal Co., and will work the coal that can be taken out of the shaft and strip the coal that is too near the top to be mined. The company has invested $30,000 in stripping machinery, and the dirt taken off the coal will be shipped to Chicago for use in filling up the lake front.

Iowa

Des Moines—Miners of district No. 13, United Mine Workers, in convention here May 18, refused to accept the wage scale agreement, submitted by the subcommittee of operators and miners. The convention adjourned after refusing its scale committee another chance to confer with the operators. The delegates voted to submit the proposition to a referendum vote of the mine workers.

Kentucky

Van Lear—The mines of the Consolidation Coal Co. at this place have been closed for some time on account of a strike. Trouble arose over an attempt at organization of the miners and the appointment of a check weighman.

Madisonville—Because of the delay in making payments on the 50,000 acres of coal rights recently purchased from farmers in this vicinity by a French syndicate, threats are being made that the deal will be called off. The syndicate, represented by William Lynch, of Dawson Springs, closed the deal for coal rights in what is known as the Beulah fields, at a price of $10 an acre. Payments have been slow and irregular, and hence the dissatisfaction.

Louisville—The Leahy Coal Co., Dougherty & Lanning and the Asher Coal Co. have been merged and taken in by the Southern Coal & Coke Co. The Asher plant which was taken over is one of most uptodate coal elevators in the country, and the largest in the South. As a result of this purchase, the output of the Southern company's mines in the Jellico district of Tennessee will be greatly increased, it is said. The transaction has been pending for some time.

The Cincinnati, Licking Valley & Virginia R.R. has filed articles of incorporation with the Railroad Commission of Kentucky. The company is incorporated with $80,000 capital stock. J. B. Walker, of Birmingham, Ala., is principal stockholder. The railroad company will build a line from Cynthiana, Ky., into the coal fields to the eastern part of the state, following the valley of the Licking River.

Harlan—The extension of the Louisville & Nashville RR. Co., from Harlan to the mining properties in that vicinity, has been completed and a number of important new producers are now shipping. The Clover Fork Coal Co. has begun production, and the Harlan Town Coal Co. will be ready to ship within two weeks. The Harlan Coal Mining Co., which recently let contracts for its equipment, will not be ready to begin operations until early in the fall.

Barbourville—The Interstate Coal Co., of Barbourville, which has been buying a great deal of property in the Brush Creek field of Knox County, has paid $250,000 for the 4000 acres of coal land of the Cumberland Coal Co. The property has three large mines in operation and others are to be opened. George L. Carter, who controls the Interstate Coal Co., has made investments of over $1,000,000 in the Brush Creek field.

Middlesboro—The Fork Ridge Coal & Coke Co., of which C. S. McManus is president, has just installed two Montgomery washers at its mines. The Winona Coal & Coke Co., which is controlled by the same interests, is installing a washer plant made by the American Concentrator Co. A 300-ton Montgomery washer has been installed at the mine of the Columbia Coal Co., of Gronty County. The washer is electrically operated. The capacity of the mine is 350 tons a day.

Missouri

Kansas City—An arbitrator to settle disputes between the coal miners and operators of the Southwestern district, was selected, May 15, by the general committee that for three weeks had been threshing out the terms of a new 2-year contract.

Montana

Great Falls—The annual convention of district No. 27, United Mine Workers, which district includes Montana, will be held in Great Falls, beginning Aug. 10. This convention will decide on the wage scale to be demanded under the next agreement. It is expected that it will be attended by about 100 delegates from the miners' unions.

Ohio

Hamden—The Superior Coal Co., operating a group of mines in Jackson County, is in a receiver's hands, but the business of the company will be continued. On May 18, the Knickerbocker Trust Co., of New York, filed suit to foreclose a mortgage to the amount of $193,000. Mr. Hersloff, of New York, has been appointed receiver, pending foreclosure proceedings. The company owns 8800 acres of coal lands and 4000 acres of mineral rights, near Wellston, Coalton and Jackson, with office in Jackson.

Coshocton—Seventy-five men at the Morgan Run colliery, recently went on strike in sympathy for the mine mules. The men stated that they did not think that the mules received proper treatment and said that they would remain on strike until assured that the mules would be humanely treated.

Columbus—Some dissatisfaction is felt by machine miners over the fact that the 4c. increase granted under the Cleveland wage settlement will, with the exception of a small fraction, go to the loaders. It was this point that protracted the session of the Hocking subdistrict joint convention, which adjourned recently after a ten days' stormy session. The operators were in favor of a larger share going to the machine men.

The Pomeroy Coal Co., of Columbus, has been incorporated with an authorized capital stock of $50,000, to take over the property of a company of the same name, which was chartered under the laws of West Virginia. The property consists of

600 acres of coal lands at Hobson, in the Pomeroy Bend field and is one of the best mines in that district. The product of the company will be handled through the Maynard Coal Co., of Columbus.

Zanesville—The Saltillo Coal Co., which has operations at Saltillo, recently sustained the loss of a large power house by fire. The company suspects that an incendiary is responsible for the loss. The plant will be rebuilt.

Crooksville—With the resumption of work at the two largest mines in the Crooksville district, May 22, the coal trade in this part of the state took on renewed activity. Practically every mine in the district is now at work and steady operation is predicted.

Pennsylvania

Bituminous

Pittsburgh—An investigating committee, consisting of three members of the international executive board United Mine Workers, met here, May 25, to investigate the affairs of district No. 5. It is charged that the abrupt adjournment of the convention, Apr. 17, was illegal and Francis Feehan, district president, is threatened with impeachment by supporters of Michael Halapy, a rival candidate for the presidency.

It is rumored that the Pennsylvania R.R. may undertake the acquisition of the Buffalo & Susquehanna R.R. and the construction of 30 miles of connecting track. This would provide a route from Punxsutawney to Pittsburgh, 30 miles shorter than any existing line and would open up a large area of virgin coal territory. One of the largest coal operations in the section is located at Sagamore, and it has developed that the Buffalo & Susquehanna Coal Co. has under lease nearly all the accessible coal for a distance of about 16 miles south of Sagamore.

Johnstown—The Wilmore Coal Co., which is the land-holding concern of the Berwind-White Coal Mining Co., has purchased about 300 acres of land in Crab Valley, about 10 miles from Windber and it is understood that coal will be mined on the property and a tipple built. Rumor also has it that a railroad connection will be built across the Allegheny Mountain, through the Kinzey gap.

Undeveloped coal lands in the Jenner region are rapidly being optioned and it is believed that the agents are working in the interests of the Western Maryland R.R. Coal land in Milford, Black, Middlecreek and Upper Turkeyfoot Townships is being bought. The securing of options by agents of the Western Maryland has been interpreted by property owners in that district to mean that the road is contemplating the extension of their tracks from Rockwood. In case the branch is built, the connection with the main line will probably be made at Rockwood, and will extend through the Glade Run district.

Dubois—The Logan Coal Co., of Beaverdale, has just completed a large fan at its No. 4 mine and added additional territory, which will mean a larger output. The company has also added about 800 acres to the No. 2 mine, and improvements will be made.

Anthracite

Scranton—Practically every mine in the anthracite region resumed operations Wednesday morning, May 22, the mine workers reporting for work in accordance with the order of the United Mine Workers of America, calling off the seven weeks' suspension. Scarcity of labor confronted the mine bosses, and while the collieries are operating, it was stated that the mines would not come near producing the normal amount of coal for some time to come. The scarcity exists chiefly among miners and laborers. So far as company work is concerned, there is no appreciable lack of men and boys.

Wilkes-Barre—Hundreds of miners have arrived here from western Pennsylvania, whence they journeyed when the anthracite mine suspension began. They were attracted home by the announcement that the hard-coal mines have resumed operation.

The fight of the Ridgewood Coal Co. against the Lehigh Valley R.R. Co., because of the railroad's failure to provide switching facilities at the Ridgewood property, at Newport, Luzerne County, assumed the form of a $500,000 lawsuit, May 23. The case was threshed out before a commissioner for the Interstate Commerce Commission a year ago. The coal company complained that the railroad company had refused to install a switch connecting the plant with the main line of the Lehigh Valley, and, further, that the road refused to permit the coal to be carted by team across its tracks. The Interstate Commerce Commission decided in favor of the coal company and ordered the Lehigh Valley to install the switch.

Hazleton—The men at the strippings of J. H. Dugan & Co., who went on strike recently, returned to work, May 24, when a 5½ per cent. wage increase was granted. The nine-hour shift was refused. The employees at the strippings of Benjamin & Co., at Harleigh, went out, May 24, for a 10 per cent. advance and a nine-hour day. Work has been resumed at the Janesville colliery of the Lehigh Valley Coal Co., where the men struck, May 22, because of the failure of 12 of their number to join the union. The miners at the collieries of the Lehigh & Wilkes-Barre Coal Co. gave notice recently, that if the nonunionists at those operations did not become identified with the United Mine Workers, all would go on strike.

Rhode Island

Portsmouth—The Rhode Island Coal Co.'s property was sold at a receiver's sale at Newport, May 17, for $50,000, to Robert G. Hay, of Boston, secretary of the old company. His was the only bid. It is the intention of the stockholders to reorganize under the name of the Portsmouth Coal Co., with a capital of $800,000, and the board of directors of the reorganized company will probably consist of Robert M. Burnett, H. M. Whitney, W. H. Joyce, W. F. Carlin and Joseph Weeks, all of Boston. William F. Dodge, mining engineer, estimates that on an output of 120,000 tons per annum the profits should be $124,760, equivalent to 15½ per cent. on $800,000 capital.

West Virginia

Charleston—By the formation of the Standard Fuel Co., of this city, capitalized at $7,000,000, the gas interests of Charles W. Swisher, including the Swisher Oil Co.; oil and gas property in the New Straitsville district of Ohio, and in Ritchie and other counties in this state, were taken over. In addition to these interests it is reported that the oil and gas and some coal interests of the Chilton, MacCorkle & Chilton firm, including those of United States Senator Chilton, are also in the combination. It is also reported that considerable Philadelphia capital is brought into the combination.

Wheeling—The miners' convention, which had held meetings in this city during the preceding week for the purpose of trying to settle the differences with the operators of the Fifth Ohio subdistrict, went into session again, May 20, to take up charges preferred against President John Moore by two of the locals represented at the convention.

Bluefield—It is generally reported that the Greeno and Bruce mines, located a short distance from Coeburn, have changed ownership. It is thought the mines will become part of the Mingo Hollow Coal & Coke Co.'s operations.

Great Britain

London—Four men are known to have been killed and many injured, May 18, in a mine explosion near Newport, in Monmouthshire. There was an unconfirmed report that 18 persons had been killed.

The Federation of Miners adopted resolutions, May 22, declaring that under the decisions of the minimum-wage boards in many districts, especially in South Wales, the men are unable to make even living wages. The federation demands that Premier Asquith at once call on parliament to amend the law to remedy the defects already apparent.

Personals

Edgar Kudlick, consulting mining engineer of the Lehigh Valley Coal Co., was recently a visitor in New York.

F. W. Wiegand has been appointed shipping agent of the Davis Coal & Coke Co. with headquarters at Cumberland, Md.

W. B. Geary has resigned his position with the H. C. Frick Coke Co. to become superintendent of the Elm Grove plant of the W. J. Rainey Coke Co.

John Steele, of Alma, Kan., has been chosen by the operators and miners of the Southwestern district as arbitrator in all disputes which may arise in this field.

W. E. Hartman, of Joliet, Ill., recently delivered a lecture on "Byproducts of Coke Ovens" before a meeting of the Engineers Society of Western Pennsylvania in Pittsburgh.

James Needham, president of the St. Paul Coal Co., the coal-mining subsidiary of the Chicago, Milwaukee & Puget Sound R.R., has left for an extended business trip to Montana.

William Z. Price, mining engineer, with the Tennessee Coal, Iron & R.R. Co., has resigned his position at Birmingham, Ala., to accept a similar position with the Pittsburgh Coal Co. at Pittsburgh.

W. C. Perry has been appointed chief engineer of the Davis Coal & Coke Co. with headquarters at Cumberland, Md. Mr. Perry is a Western man who has been in the employ of the company for a number of years.

F. R. Wadleigh, fuel engineer and assistant general manager of the Chesapeake & Ohio Coal & Coke Co., recently visited Akron, Ohio, where he was interested in the demonstration of a new chain-grate stoker for coking coals.

C. J. Johnson, until recently division engineer of the Blockton Coal Mine division of the Tennessee Coal, Iron & R.R. Co., has been appointed assistant superintendent of that division with headquarters at Blockton, effective June 1.

Frank Peabody, of Chicago, president of the Peabody Coal Co., in company with W. L. Ross, vice-president of the Chicago & Alton R.R., recently visited a number of mining properties, in which he is interested, in the vicinity of Springfield, Ill.

H. S. Mervin, of Columbus, Ohio, has been elected secretary-treasurer of the New Pittsburgh Coal Co. to fill the vacancy caused by the death recently of Harry R. Beeson. Mr. Mervin has been with the company for 10 years and has been auditor since 1906. James A. Rundio has been appointed general sales agent, and W. D. Morse has been made auditor.

Obituary

Clarence S. Whitney, prominently identified with the coal business of Kansas City, Mo., for the past 25 years and lately affiliated with the Gray-Bryan Coal Co., died, May 15, at his home in that city. Mr. Whitney was born in Clinton, N. Y., in 1850.

Allen H. Horton, aged 58, for a number of years general manager for the Pittsburgh Coal Co. and widely known in coal and navigation circles throughout the Great Lakes region, died, May 21, at Solon Springs, Wis., where he had gone in quest of health. Maj. Horton lived for a number of years in Buffalo, N. Y., where he was connected with the Lehigh Valley Coal Co. From there he went to West Superior, Wis., as general manager of the new Lehigh Coal & Iron Co. and later became vice-president of the Youghiogheny & Lehigh Coal Co., in St. Paul. He leaves a widow and one son

Publications Received

FIRST ANNUAL REPORT, U. S. BUREAU OF MINES. Joseph A. Holmes, director. 57 pp., 6x9 in., illus. Government Printing Office, Washington, D. C.

LOCOMOTIVE DRAFTING AND ITS RELATION TO FUEL CONSUMPTION. By H. B. MacFarland. 85 pp., 6x9 in., illus. The International Railway Fuel Association, Chicago.

AN INVESTIGATION OF THE COALS OF CANADA. By J. B. Porter, R. J. Durley and special staff. Vol. I, 233 pp., 6½x10 in., illus., 62 plates, 31 drawings, 5 maps. $1. Government Printing Bureau, Ottawa.

This is the first of six volumes which will embody the report of investigations that have been carried on since 1906, under the direction of the Mines Branch of the Canadian Geological Survey. The work was conducted in the laboratories of McGill University, by Dr. Porter, head of the mining department, and a specially selected staff. The following subjects are covered in Vol. I: The coal fields of Canada; collecting coal samples; sampling in the testing plant and laboratory; coal washing; and the manufacture and testing of coke.

Trade Catalogs

The Manhattan Drilling Co., New York. Pamphlet. The Dobbins core drill. 20 pp., 6x9 in., illus.

The "S-C" Regulator Co., Fostoria, Ohio. Pamphlet. 24 pp., 6x9 in., illus. Descriptive of "S-C" boiler feed-water regulators.

The Goulds Manufacturing Co., Seneca Falls, N. Y. Bulletin No. 110. Single Stage, Double Suction Centrifugal Pumps. 16 pages, 7¾x10 in., illustrated

Ingersoll-Rand Co., 11 Broadway, New York. Bulletin, form 7004. 12 pp., 6x9 in., illus. This catalog is descriptive of Cameron steam pumps. It shows the different styles manufactured and gives tables of sizes and capacities, together with prices.

Construction News

Brockwayville, Penn.—The McKnight Coal Co. is planning to make improvements and install additional equipment.

Duquoin, Ill.—The Majestic mine is receiving figures on an electrical plant and other improvements, to cost about $25,000.

Marion, Ill.—The Scranton Big Muddy Coal Co. is receiving bids for new boilers, and also for an electrical plant to replace the air plant now in operation.

Connellsville, Penn.—The Unity Connellsville Coke Co. is taking bids on the construction of 20 new ovens. Contract will be awarded in the near future.

Birmingham—The Queen Quality Coal Co., recently incorporated, will develop 240 acres of coal land and will require equipment. Simon Levy, Birmingham, is president and treasurer.

Marquette, Mich.—The Pittsburgh Coal Co. has acquired the George Kemp coal dock at the Soo and is reported to contemplate increasing its capacity to 40,000 tons at an expense of about $100,000.

Johnstown, Penn.—The Wilmore Coal Co.—a Berwind-White subsidiary—has purchased 300 acres of land near Reitz, in the Crab Valley, and it is reported that a mine will be opened and a large tipple built.

Christopher, Ill.—The Christopher Coal Mining Co., composed of a number of former officials of the Zeigler District Colliery Co., is to sink a new mine two miles from this place. Work will commence within the next week or two.

Marion, Ill.—The St. Louis Coal & Coke Co., of St. Louis, has bought the White Ash mine of the defunct Standard Collieries Co. It is understood that the new owners will spend several thousand dollars in improving the mine and the washer.

Knoxville, Iowa—The Anderson Coal Co., of Des Moines, is preparing to sink a new shaft on coal property in East Knoxville township, four miles from here. A spur track is being extended from Flagler to the new shaft, a distance of one mile, by the Rock Island R.R.

Dubois, Penn.—The Beaver Run Coal Co., of Beaverdale, will make a second opening on its property and equip the new mine with electric motor haulage and electric cutting machines. A ventilating fan is being installed. The workings will have a capacity of 1000 tons daily.

Duluth, Minn.—The Pittsburgh Coal Co. has awarded a contract to the Barnett & Record Co. to extend its No. 5 coal dock at Allouez Bay, 1200 ft., which will give it a total length of 3500 ft. by 450 ft. wide. It will then have a storage capacity of one million tons and be the biggest coal dock in the Duluth-Superior harbor. The estimated expenditure is $300,000.

Ridgway, Penn.—The Hyde-Murphy Co., of this place, has been awarded the contracts for the construction of three mining towns in Indiana County. One is with the Jefferson & Clearfield Coal & Iron Co. for the erection of 50 modern houses at Jacksonville. Another is for the erection of 75 houses at Lucerne, for the Rochester & Pittsburg Coal & Iron Co., and the third is for the erection of 50 houses at Yatesboro for the Cowanshannoc Coal & Iron Co. New mines will be opened at those places.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

During the past week, new anthracite circulars have been announced at most points, showing advances ranging from 15c. to 50c. per ton. These have brought forth a number of strong protests from the public, and the demand is not so brisk as was expected, consumers believing that little can be gained by storing at the new prices.

Quotations in the Eastern bituminous markets are nominally being held, but there are well defined rumors of cutting and orders are generally scarce all along the line. Reports of a labor shortage at the mines, necessitating a curtailment in production, is the most encouraging feature in the trade at the present time. With anthracite again coming in, the soft coals will have to stand on their own merits and have settled down to the customary summer lethargy.

Mines in the Pittsburgh district are only working 60 to 65 per cent. capacity, orders being light and mostly on Lake business, with few contracts being renewed. The Lake shipping is now on in full blast, and as a result, there is considerable activity in the Ohio fields; the opening was late this season, and the operators are now endeavoring to catch up. While business continues good in the West Virginia fields, there has been a decided easing off in the strong demand and heavy movement which have been in effect there.

The resumption of work in the Kentucky fields has weakened the spot market in Alabama, but it is still fairly strong and more active than at this time last year. The Middle Western trade is in a peculiar position. The long shutdown at the Indiana mines has resulted in an acute shortage at some points, while the St. Louis market, on the other hand, is being flooded with a heavy over-production, as a result of which coal is being freely offered at prices less than the cost of production.

Boston, Mass.

In the Eastern market there is no real change from a week ago. Pocahontas and New River prices are being normally held, but there are well defined rumors of low figures being quoted to place spot coal. Such business has enabled a few shippers to dump coal that was standing at the piers and so relieve the operators of any threatened embargo. The outlook on contract is no brighter, and all the agencies are becoming anxious. A few consignment cargoes at Providence and Portland have helped spread the idea among buyers that trade is to be slack through the summer, while a reported shortage of labor in West Virginia is the most favorable news heard this week.

The Pennsylvania shippers are combing over the market and few are pretending to get any advance over last year's prices. Georges Creek has slowed down along the line. The rush for anthracite for the present, and orders are scarce all will tend to curtail the tidewater movement of Georges Creek for a month or two anyway. All-rail trade is better in tone, and for the higher grades there is steady demand.

There is much comment over the new anthracite circular just given out by the companies. With the 25c. general advance and the loss of two months' shipments, the dealers stand to pay a 45c. greater opening price than in April last year, with not a good prospect of getting much June coal at that. The Boston retailers announced spring prices effective May 27 as follows:

Broken	$6.75
Egg	7.25
Stove	7.50
Chestnut	7.75
Pea	5.75
Franklin	8.75
Shamokin	7.75

These are 50c. higher than last year's summer prices on domestic sizes. There will doubtless be criticism from the public, when the actual advance to the mine workers is generally understood to be so small. The first shipments are expected to leave Philadelphia soon after June 1.

Wholesale prices on bituminous are as follows:

Clearfields, f.o.b. mine	$1.10 @ $.35
Somersets, f.o.b mine	1.20 @ 1.35
Georges Creek, f.o.b. Baltimore	2.70 @ 2.80
Pocahontas, New River, f.o.b. Hampton Roads	2.70 or less
Pocahontas, New River, f.o.b. cars Providence	3.35 @ 3.50
Pocahontas, New River, f.o.b. cars, Boston	3.45 @ 3.60

New York

Anthracite—Some of the anthracite companies have announced their new circular, effective June 1, during the past week. These show a nominal increase of 25c. a ton on egg, stove, chestnut and pea, the last being one of the steam sizes which it was thought would not be affected. Buckwheat Nos. 1, 2 and 3 remain unchanged.

The grades advanced represent 60 per cent. of the production, and amount to a net gain of approximately 15c. per ton. The present schedule is not meeting with much approval from either consumers or the companies, and has not yet been adopted bv a number of the more important selling concerns.

We quote the new prices 25c. higher on the four sizes mentioned, as follows:

Broken	$4.50
Egg and stove	5.25
Chestnut	5.50
Pea	3.50
Buckwheat	2.75
Rice	2.25
Barley	1.75

Bituminous—The bituminous market is slow and the next month or two will see little outside of the routine business being done. The trade is still feeling the effects of the heavy storing done previous to the strike, although conditions are not far from normal for this period of the year.

The movement is confined entirely to contracts, and there is little call for spot coal, on which low figures are being quoted. The arrivals are, however, quite heavy, and with rumors of a labor shortage at the mines, there is a general good feeling among the producers. We continue to quote prevailing prices as follows:

West Virginia steam	$2.35
Ordinary grades, Pennsylvania	2.45
Fair grades, Pennsylvania	2.55@2.65
Good grades, Pennsylvania	2.70@2.80
Best Miller, Pennsylvania	3.00
Georges Creek	3.15

Pittsburgh

Bituminous—The coal market continues very slow, demand being far from expectations. While manufacturers are fairly busy and using almost the normal quantity of coal, their purchases are relatively light, indicating heavier stocking than was estimated prior to the suspension. The mines are running slightly better, but chiefly on coal to fill regular contracts in the Lake trade; there has not, however, been as much new buying as was expected in this branch. Operations are estimated at between 60 and 65 per cent. of full capacity and at some mines there is difficulty in securing men. We repeat former quotations, although they are largely nominal: Mine-run and nut, $1.22½; ¾-in., $1.32½; 1¼-in., $1.47½; slack, 82½c., per ton at mine, Pittsburgh district.

Connellsville Coke—Connellsville furnace coke for second half delivery has sold at $2.50, the highest price for more

than two years, and the price which a few weeks ago operators were hoping they would get but which they did not expect until considerable cheaper coke had been sold. The $2.50 sale was a contract for 12,000 tons a month over the second half. Previous contracts reported in the past few weeks for second half were two for 10,000 tons a month each, at $2.35, and one for 6000 tons a month at $2.40.

The operators are now all asking $2.50, but consumers are slow to take hold. Contracts made thus far involve about 38,000 tons a month, but there is still not far from 150,000 tons a month to be covered, against contracts which expire June 30. There are, of course, a number of contracts made for the whole year, as well as many term contracts running for a period of years.

A curious feature is that foundry coke has not advanced in consonance with furnace coke, good grades being offered for the year beginning July 1 at all the way from $2.35 to $2.50, though some operators hold their coke at $2.75 or higher.

Prompt furnace coke has eased off, and can readily be had at $2.25, while some odd lots have been sold at less. The decline is due to a temporarily good supply resulting from several furnaces unexpectedly blowing out. With this decline in prompt it will be harder for producers to sell at $2.50 for second half. We quote: Prompt furnace $2.25; contract furnace, $2.50; prompt foundry, $2.35@2.50; contract foundry, $2.35@2.50.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending May 11 at 398,956 tons, a decrease of 3000 tons, and shipments at 4385 cars to Pittsburgh, 6248 cars to points west and 1309 cars to points east, a total of 11,942 cars, a decrease of 49 cars.

Philadelphia, Penn.

As was predicted, the prices sent out by the anthracite operators saddled all of the increase that the miners will receive on three sizes, namely, stove, chestnut and pea, the prices for this market in the line trade now being as follows:

Broken (on contract)	$3.00
Egg	3.75
Stove	4.00
Chestnut	4.15
Pea	2.50
Buckwheat	1.50
Rice	0.85

On egg, stove and chestnut, there is a concession of 30c. per ton on any shipment made during the month of June. The increase noted above is 25c. on stove, 15c. on chestnut and 50c. on pea. The large increase on pea size is, no doubt, due to the fact that there is a steadily growing market for this size, particularly in this vicinity. Many householders use it for domestic purposes, and as it is understood that the output of this size is growing less, owing to improved methods of mining, and the natural offspring of a curtailed output, coupled with a heavy demand, is a higher price. The contract price of broken, which was advanced the first of the year at tidewater, still remains at the same figure of $3 for line business. The relative difference between stove and chestnut has been reduced to 15c. instead of 25c., as was the case all of last season. The prices of buckwheat and rice have not been changed in any way. At tidewater, there has been an advance of 25c. on all sizes.

The demand for coal is not as brisk as might be expected. Dealers report that there is slight increase, but the fact that there is so little to be saved by laying in stocks now, as against the fall, has caused many to postpone purchases until later. Retail prices are $6.75 for egg, $7 for stove and $7.25 for chestnut.

Buffalo, N. Y.

If the anthracite miners had stayed out longer it would eventually have had some effect on bituminous prices, but there is hard-coal enough so that all other fuels will have to stand on their own merits in the future. As a rule the bituminous dealers are not very hopeful. One of the operators says that he has made up his mind to lose money for three months or so.

There is no relief promised from the tidewater district. Reports from the market agree that it is "plugged full" of coal and promises to remain in that condition, perhaps all summer. Only a few operators here get into that market, but it affects the trade as a whole. There is not much coal unsold on track here, but it is said that there is considerable at various points in Canada.

The regular prices on bituminous hold, but they cannot be called strong, at $2.57½ for Pittsburgh three-quarter, $2.47½ for mine-run and $2.10 for slack. Coke is also rather weak at $4.50 for best Connellsville foundry. Furnaces in this district are running only moderately, some of them being idle.

The announcement of a general advance of 25c. in anthracite has resulted in much adverse comment, as it more than covers the increased pay to the miners so the consumer comes in for the whole of it, together with a small bonus to the operator. A supply is already on the way, though there has been no particular demand for it during the suspension.

As to the Lake trade all effort will now be made to keep the fleet busy till the lost ground is regained. If the Eastern demand is not large there will soon be a record-breaking activity on the lakes, for the trade is already nearly 20 per cent. behind last season to date. Some of the anthracite companies can make big spurts in mining, but not all of them. Tonnage has been taken at 30c. to the principal Lake Michigan ports, a small reduction from former seasons, and the same to Lake Superior ports.

Baltimore, Md.

Every vestige of the strike of the coal handlers in Baltimore has disappeared, and normal conditions now prevail at all of the railroad piers. While the settlement of differences between the coal handlers and their employers was a thing much to be desired, it has not brought about any marked improvement in the local market, so far as the demand is concerned. The market during the past week was heavy to say the least, and, consequently, prices were low.

For the past two or three weeks, there has not been the consumption that the trade expected at this time of the year, and not a few of the Baltimore operators are feeling the effects. Many mills, which are usually good customers, are now being operated on short time, and this is being reflected in the coal market.

Five steamers arrived in Baltimore during the week to load coal for Alexandria, Egypt. In all, about 22,000 tons of the product will be forwarded to that country.

President Bushrod M. Watts, of the Baltimore Coal Exchange, made an announcement during the week to the effect that the winter prices for anthracite would, in all likelihood, be maintained throughout the summer. The rates for the ensuing year will not be definitely fixed here until after June 1, but it is believed by the consumers here that the operators intend to keep up the winter prices and local retailers will be compelled to follow suit. Every year during the summer months there has been a reduction of 50c. on hard coal, but, according to Mr. Watts, this low price will not prevail this year.

Cleveland, Ohio

The market for steam coal still remains quiet, and dealers are buying very little domestic coal for stocking purposes; outside of renewing contracts, operators and jobbers are not doing much. Prices on No. 8 coal have dropped from 7½ to 10c. per ton, slack selling at 55c., mine-run, 90c. and ¾-in., $1. As Lake production increases, the price seems to go lower, unless there is a concerted movement to hold it back from the market by track shortage.

Shipments of coal for the Lake trade have been quite large, but the supply of tonnage is far in excess of the demand, and the boats are delayed in loading.

Vessels are waiting at most of the docks, and in some cases have to make two ports to fill out cargoes. There will be a little hard coal next week, but it will be June 10 before there is much demand for tonnage in that trade.

Columbus, Ohio

The situation in Ohio is improving as the season progresses and activity now prevails in every branch of the coal trade with the exception of domestic. Prices are ruling firm and everyone engaged in the coal business is looking forward to a rather prosperous season. Since the mines have resumed operations, there has been considerable improvement in general business conditions which is being reflected upon the coal trade.

The opening of navigation was delayed because of ice in the Soo but now the season is on in full blast. The activity in the ore trade is aiding in a better movement of coal and the chartering of boats is going on actively. Some little trouble in the lake trade was caused earlier in the season by the decrease of 10c. a ton made by one of the largest shippers but the effects of this are rapidly passing away. The docks are now taking coal better and there is every prospect for an active trade during the entire season. Ohio lake shippers are preparing to ship even a larger tonnage than in 1911.

Railroad fuel contracts are the next thing to attract the attention of operators. Many of the larger railroad contracts will be renewed soon and there is some lively bidding. Operators hope to have more than a 5c. increase on these.

There is a fair demand for fine coal and a large amount of it is being made in connection with the lake trade. Prices on that grade are ruling firm.

Prices which prevail in Ohio fields are:

Hocking Valley	
Domestic Lump	$1.50
¾-in	1.35
Nut	1.15
Mine-run	1.15
Nut, pea and slack	0.80
Coarse slack	0.60
Pittsburgh No. 8	
¾-in	1.30
Mine-run	1.05
Coarse slack	0.65
Pomeroy Bend	
Domestic lump	$1.50
¾-in	1.35
Mine-run	1.15
Nut, pea and slack	0.75
Coarse slack	0.55
Kanawha	
Domestic lump	1.50
¾-in	1.30
Mine-run	1.10
Nut, pea and slack	0.60
Coarse slack	0.50

Hampton Roads, Va.

The market at Hampton Roads during the past week has been quieter than at any time since the first of the year, but there has been a fair loading at the three ports every day. Shippers are now feeling the effects of the heavy stocking in anticipation of the coal strike during April. The greater portion of the movement now is on old contracts, but it is predicted that the situation on new contracts will shortly adjust itself. The prevailing price at Hampton Roads is now $2.70.

An interesting feature of the past week is the returns on coal from Hampton Roads to Boston for the first quarter of 1912. The total tonnage during the first quarter of 1911 was 212,568 tons, as compared with 430,248 tons this year, or an increase of over 100 per cent. This goes to show there was considerable activity at Hampton Roads, and the impetus thus far gained is sure to hold up at this port throughout the balance of the year.

Charleston, W. Va.

It is now practically certain that the month of May will see the heaviest production in the history of the Kanawha valley and likewise be the banner month in the number of tons shipped from West Virginia over the Chesapeake & Ohio. Cars have been plentiful, and the mines have been taking advantage of the opportunity. On the Chesapeake & Ohio the movement has been excellent, due to the borrowing of a number of engines from other roads. Along the Kanawha & Michigan, however, hundreds of T. & O. C. cars, already loaded, may be found crowding the sidings, awaiting movement to the lakes.

Prices have remained firm for some time, and are what operators declare to be good, considering the extremely low rate that obtained before the first of the year.

A number of the companies, owing to the good prices now prevailing, have signed the scale and are now in partial operation. These include the mines, about twenty in all, that did not sign the agreement some time ago in the Kanawha district.

Birmingham, Ala.

The Birmingham coal market continues fairly strong, though spot shipments are off. Resumption of work in the Kentucky fields is responsible for this.

One of the most favorable features in this trade is the growing tendency on the part of the railroads to substitute coal for the crude oil which they have been using. The advanced prices on oil, and the difficulty which is being experienced in getting a constant supply, has led the railroad officials to regard Alabama coal as less expensive and more reliable.

One of the adverse features of recent days has been the announced determination of a leading Southern railroad to confine itself to Kentucky coal exclusively, whereas it has been a consumer of considerable Alabama coal. In spite of this, there is probably more Alabama coal being sold for railroad use now than ever before. Improved facilities for loading coal to bunkers are also being rapidly perfected at New Orleans. During the past few days, the movement to river points and beyond has improved.

Indianapolis, Ind.

This has been a strenuous week in the Indiana market. Comparatively few mines have been working and long lines of cars have remained idle on the sidings. The public-service companies have, by dint of economy, secured enough coal to keep going, but this condition cannot last long.

Interest is concentrated on the joint conference being held at Terre Haute, and the prospects for a general resumption are much brighter than a week ago. The demand for a weekly pay, as provided in a statute enacted by the last legislature, which is of doubtful legality, has been holding thousands of miners in idleness; they are influenced by the radical element, who declare that they will never consent to an agreement that does not provide for a weekly pay. Now that the question is to be voted on, there are those who greatly fear that the vote will be adverse to waiving the weekly pay law.

St. Louis, Mo.

The Illinois mines still continue to open up, and the local market is almost stagnant. It seems to be a contest to see who can lose the most money in the shortest space of time, and all this in view of the fact that the fifth and ninth district operators have an organization and ought to know what their coal is costing them. The price of Standard lump has gone down to 80c. and mine-run is practically the same. The Carterville operators are getting a living price for their coal, but there are indications that they too will lose control of their market.

Nearly every railroad in East St. Louis has coal on track undisposed of, and this condition will probably continue from this time until early fall. Operators in the central portion of Illinois are shipping some coal to Indiana, on account of the shut down there.

The market is as follows:

Carterville	
6-in. lump	$1.25 @ 1.35
3x6 egg	1.25 @ 1.35
Nut	1.20 @ 1.30
Screenings	1.05 @ 1.10
Mine-run	1.00 @ 1.00
Standard	
2-in. lump	$0.80 @ 0.90
Mine run	0.80 @ 0.90
Screenings	0.85 @ 0.95

Minneapolis—St. Paul

It is rather hard to determine the sentiment of the market at present, with conditions dull and backward, as they have been for some weeks past. The prospects are very good, but they are almost wholly anticipatory, based upon the new crop, and the result is that little is being done in advance of present needs.

Contracting with steam users for the season is progressing very slowly; hardly any of the buyers are willing to take up the subject, because during the past two years contracts have proved to be less attractive than spot buying.

The advance of 25c. a ton on anthracite will have a tendency to stall the movement from the docks until later in the summer, as dealers and consumers will not be given any inducement to buy now.

Prices to dealers and steam users are being quoted as follows:

Youghiogheny	
Lump and stove	$3.40
Dock run	3.10
Screenings	2.40
Hocking	
Stove and nut	3.40
Dock run	3.00
Franklin County	
Lump, egg and nut	1.50
Mine-run	1.20
Screening	1.15
Carterville	
Lump and egg	1.50
No. 1 washed	$1.60@1.70
No. 2 washed	1.40@1.50
Harrisburg	
Domestic lump and egg	1.50
Steam lump	1.40
Mine-run	1.20
Screenings	$1.10@1.15
Springfield	
Domestic lump	1.50
Steam lump	1.25
Mine-run	1.15
Screenings	1.10

Portland, Ore.

Just now there is practically no demand for coal, excepting such as is required by the railroads and manufacturing establishments, which fluctuates very little. The weather has been warm except for a few days of rain, and indications are that from now on there will be little business for some time.

This is the time of year when thoughtful people begin to order coal and wood for the winter, but dealers say that prices are too high at present to induce people to buy at this time; hence there is no business in storage coal. Australian freights are prohibitive, and there seems no inclination to reduce domestic-coal values as yet.

Until prices are shaded, dealers look for very little advance business for future wants. The usual reduction on storage coal here is $1 per ton, but dealers say they have to pay too much to justify this cut. How soon it can be done, they seem unable to predict. If present high freights from Australia continue, the domestic product will have very little opposition from that direction the coming fall.

Production and Transportation Statistics

Norfolk & Western Ry.

The following is a statement of the commercial and company coal from mines on the N. & W. Ry., for the month of April, in short tons:

From	Commercial	Company
Pocahontas	1,124,850	112,178
Tug River	160,394	43,895
Thacker	160,688	56,128
Kenova	66,021	8,807
Clinch Valley	119,616	10,978
Total	1,631,569	231,986

Tonnage from the West Virginia mines was as follows, in short tons:

From	Tipple Coal	Total Coal
Pocahontas	20,291	1,192,069
Tug River	4,607	204,289
Thacker	4,726	216,816
Kenova	6,547	74,828
Total	36,171	1,688,002

Note.—Total shipments of coke, originating entirely in the Pocahontas field, amounted to 100,906 tons as compared with 128,816 tons in March.

Chesapeake & Ohio Ry.

The following is a statement of the coal and coke traffic over the lines of the C. & O. Ry. for February and March, and the nine months ending Mar. 31, 1912, in short tons:

Destination	February	March	9 Months
Tidewater	299,459	487,236	3,092,449
East	190,655	198,472	1,671,276
West	971,416	805,017	8,261,891
Total	1,461,539	1,490,725	13,025,616
Coke	17,180	22,932	170,548
From Connections			
Bituminous	17,650	20,060	173,950
Anthracite	4,742	3,330	29,976

Southwestern Tonnage

The Southwestern Interstate Coal Operators' Association has issued the following comparative statement of tonnage for January:

State	1911	1912	Increase
Missouri	248,159	281,453	33,294
Kansas	462,624	537,928	75,304
Arkansas	143,445	155,666	12,221
Oklahoma	251,411	348,982	97,571
Totals	1,105,639	1,324,029	218,390

Foreign Markets

Great Britain

Colliery outputs continue exceptionally heavy, and, as tonnage is still very slow in arriving, there are fears of pit stoppages. Prices have receded further, and are approximately as follows:

Best Welsh Steam Coal	$4.44
Seconds	4.26
Thirds	3.96
Best Dry Coals	4.32
Best Monmouthshire	3.90
Seconds	3.72
Best Cardiff Small Coal	2.28
Seconds	2.22

Prices for Cardiff coals are f.o.b. Cardiff, Penarth, or Barry, while those of Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days, less 2½%.

The following is a comparative statement of the British fuel exports for April, 1911-12, with the total for the first four months of the current year:

Grade	April 1911	April 1912	4 mos. 1912
Anthracite	168,668	29,793	587,797
Steam	3,576,763	1,086,312	10,132,535
Gas	761,890	266,486	2,205,484
Household	105,811	45,654	344,888
Other sorts	234,749	66,326	696,939
Total	4,847,881	1,494,571	13,967,643

Financial Notes

The Pittsburgh & Erie Coal Co. gives notice that, pursuant to the terms of the mortgage, dated May 1, 1905, the trustee will receive sealed proposals up to Apr. 29 for the sale to it of bonds as described sufficient to make the sum of $13,387.03. The right is reserved to reject any or all tenders.

The following are the cash dividends paid by six of the large hard-coalers during the past 12 years:

Delaware, Lackawanna & Western	$57,500,500
Central R.R. of New Jersey	27,436,800
Delaware & Hudson	39,008,000
Lehigh Valley	23,450,473
Reading	44,100,000
Lehigh Coal & Navigation	13,775,000
	$205,270,773

The Pittsburgh Coal Co. has $27,071,800 preferred stock outstanding out of a total authorized issue of $32,000,000. Dividends are cumulative up to 7%, but the stock has not received the full rate to which it is entitled since the early part of 1905. Dividends were suspended from that year up to the close of 1909, but in 1910 and 1911 disbursements were at the rate of 5% per annum. Back dividend now amounts to approximately 36½%.

During the last 12 years more than 700,000,000 tons of coal have been mined from the properties of the principal anthracite companies and during the same period the aggregate value of these same companies has increased more than threefold. The Lackawanna is looked upon as a phenomenon, but it has increased only a little more than threefold, while Reading has increased sixfold and Lehigh Valley ninefold. The Central Railroad of New Jersey shows almost a threefold increase. The only new money put into any of these corporations is $20,000,000 to the Lehigh Valley and something over $2,000,000 into the Lehigh Coal & Navigation Co.

The United States Smelting, Refining & Mining Co. has issued $10,000,000 6% five-year collateral trust gold notes of the Utah Co., guaranteed principal and interest by the United States Smelting, Refining & Mining Co. The notes are dated Apr. 1, 1912, and are due April 1, 1917, and may be called on or after Apr. 1, 1915, at 101 and accrued interest. The notes will be secured by collateral representing entire ownership of the new railroad and interests in the coal properties. The guarantor company has no mortgage or floating debt and has only $4,000,000 of funded debt, and on Dec. 31, 1911, had net working capital of $7,641,511. Its average net profits for the last six years were nearly 4½ times the interest charges on this issue.

Every Shaft Running Needlessly

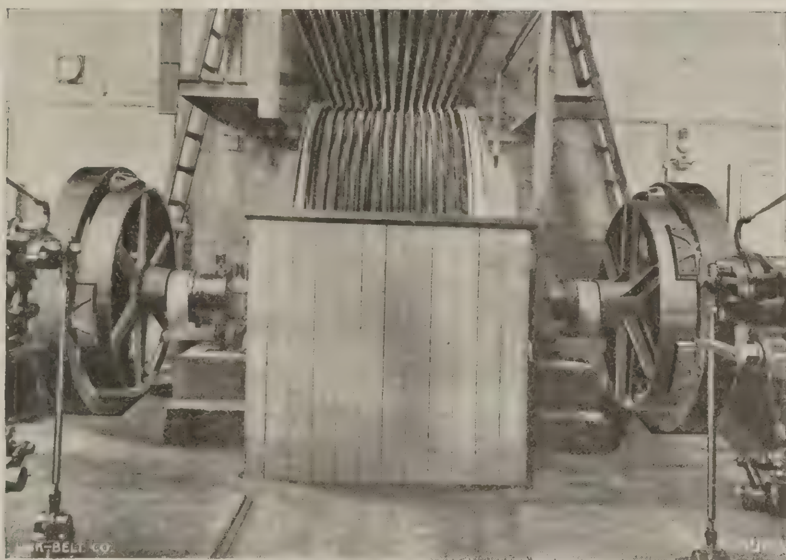
Means a Loss of Power

Friction Clutches *save* power.

The majority of clutches on the market, however, have *projecting parts*, which themselves introduce a serious element of danger, as they are unseen when the clutch is revolving. This is not true of the

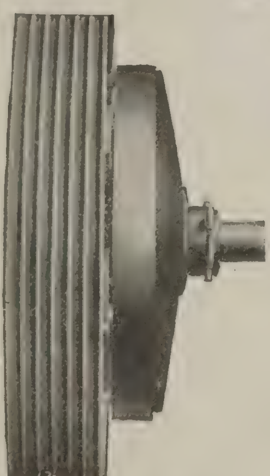
EWART FRICTION CLUTCH—

"*The Safe Clutch*"



Two 66″ Ewart Guaranteed Friction Clutches

in power house. These clutches have been in use for fourteen years, and are still in successful daily operation.



The Ewart Clutch
"The Safe Clutch"

While the Ewart Clutch, as regularly furnished, is the best protected and safest clutch on the market, we are prepared to furnish it with mechanism completely housed, as shown.

This is a feature found in no other clutch, and it is protected by patents. It makes an accident from the clutch absolutely impossible.

Everyone interested in the safeguarding of employes should read our Ewart Friction Clutch Book.

A copy will be sent postpaid upon request. Address nearest office.

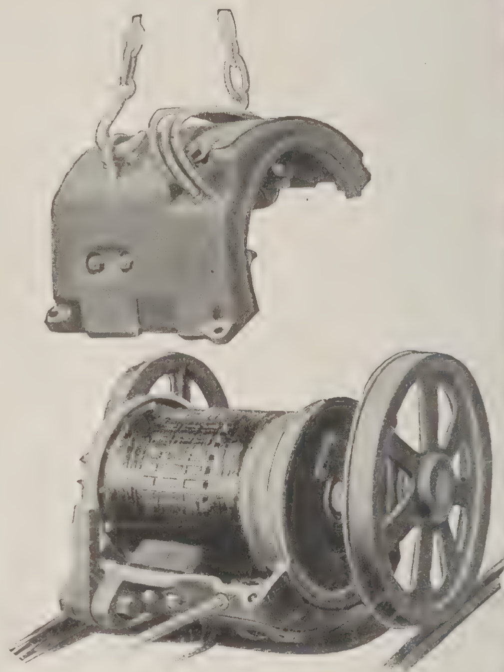
No trouble to get into the motor of a Baldwin-Westinghouse Mining Locomotive

EVERY mine operator appreciates the advantages of ready accessibility to every part of his locomotive equipment. He knows that the most satisfactory service is obtained from apparatus that can be quickly and easily overhauled.

Baldwin-Westinghouse Mining locomotives are built to meet actually existing conditions. Their design is practical in every respect.



Showing the Accessibility of the Westinghouse Mine Motor.

Every part is easily accessible. The illustration shows how readily the motor can be taken apart. The axle bearings and the suspension nose are on the bottom part of the frame. The upper part of the frame, armature, and bearing housings can be removed without disturbing the suspension or the axle brackets. Each part of the motor is then exposed for inspection. The same convenience in overhauling is found in every part of the locomotive.

Baldwin-Westinghouse mining locomotives haul maximum tonnage because their design is the result of the long experience of the Baldwin and the Westinghouse Companies with electric haulage problems of every kind. Full information on request.

COAL AGE

Vol. 1 NEW YORK, JUNE 8, 1912 No. 35

LAST week we had a few words to say concerning the desirability of scientific management as compared with rule-of-thumb methods. Continuing along the same line, we do not wish anyone to infer that we believe any single panacea exists for all labor troubles. Lazy, inefficient, selfish and cruel people will always be with us, and as a result we cannot hope to eliminate all poverty and unhappiness.

Scientific management consists in a combination of four great principles: *First*, the development of a true science, or, in other words, the substitution of a science for the individual judgment of the workman; *second*, the scientific selection of the workman; *third*, his scientific education and development; *fourth*, intimate friendly co-operation between management and men.

The problem of any management is to obtain the best initiative of every workman, and to accomplish this end, the company must give some *special incentive* to its men. The inducements generally offered are higher wages, hope of promotion, shorter hours and better surroundings. Under the most modern type of "task" management, personal initiative (hard work and good-will) is obtained by developing a science for each element of a man's work, by teaching, co-operating and sharing responsibility.

In order to perfect a system of scientific management, a company must spend some money in studying the various kinds of work. For instance, careful research has shown that a first-class laborer can be under load only 42 per cent. of the time and should be free from load 58 per cent. of the day. When carrying a heavy weight, the muscle tissues are in process of degeneration, and frequent periods of rest are required for the blood to restore these tissues.

The average manager would question whether there is any science in the work of shoveling coal, but a little thought and analysis will prove that definite laws can be formulated for this type of simple labor. There is a given shovel-load at which a man will do his biggest day's work. One investigator discovered that a first-class man will shovel a larger tonnage per day with a 21 lb. load than with a greater or less load on his shovel. It is evident that the load will vary three or four pounds, but highest efficiency is obtained when the size of shovel used accommodates an average of about 21 lb. of the material being handled.

One company after making a careful and extended investigation of this simple problem of shoveling, and after a study of all motions and the elimination of each unnecessary movement on the part of the men, selected less than 200 competent laborers, who regularly did the work formerly accomplished by 500 men working on their own responsibility with varied tools of their own selection. The fewer number of men received higher individual wages than when they worked under the old rule-of-thumb system.

It must be understood that a plan of scientific management can only be effected by selecting and commencing with one likely individual; other laborers are experimented with later and taught to perform their tasks according to definite rules, which eliminate every unnecessary motion and intelligently recognize the laws of human endurance. When workmen are herded into large gangs, instead of being treated as separate individuals, a loss of ambition and initiative is sure to result, and individual efficiency falls below the level of the worst man in the gang.

When scientific study was applied to bricklaying, the new methods raised the speed of work from 120 to 350 bricks per man per hour. The idea on the part of some union men that restriction of output is a benefit to the trade is erroneous. It should be plain to all that deliberate loafing inevitably results in making every laborer pay higher rent, and in addition drives trade away from the locality where the restrictive measures are in force. The high percentage of unemployed in England is due largely to the action of British workmen in deliberately restricting their output.

The average man will go slowly if, instead of being given a task, he is told to do as much as he can. No workman has authority to make other men co-operate with him to do work faster. It is only through *enforced* standardization of methods, *enforced* adoption of the best implements, and *enforced* co-operation, that higher efficiency can be secured. From two to four years should be consumed in making the change to scientific management, and in coal mining, the added prosperity that would result to operator and miner would be tremendous.

The Roslyn, Washington, Coal Field

By Joseph Daniels*

This is the second and concluding article on the Roslyn field, and discusses principally the methods of working. The room-and-pillar system is used exclusively, and coal is handled in the rooms by means of both chutes and gravity planes. The Washington wage-scale is given, together with some interesting notes on costs.

The room-and-pillar method of mining is the only system used in this field. One of the early mine inspectors' reports mentions that the longwall method was tried at one of the Cle Elum mines, but the experiment was not continued; it was also attempted in the Roslyn field, but abandoned there as well. No mining machines are in general use, although experiments are now being made with the Radialaxe puncher.

Methods of Working

The mines are usually opened with double slopes and entries, the cap rock being brushed to a sufficient height to obtain good headroom, about 5 ft. 6 in. above the rail. Slopes are driven from 10 to 14 ft. wide and the entries 9 ft. with 30-ft. pillars between. In some cases, the entries are driven 14 ft. wide and brushed for a width of 9 ft., the brushing being gobbed in the entry; the air course is not usually brushed.

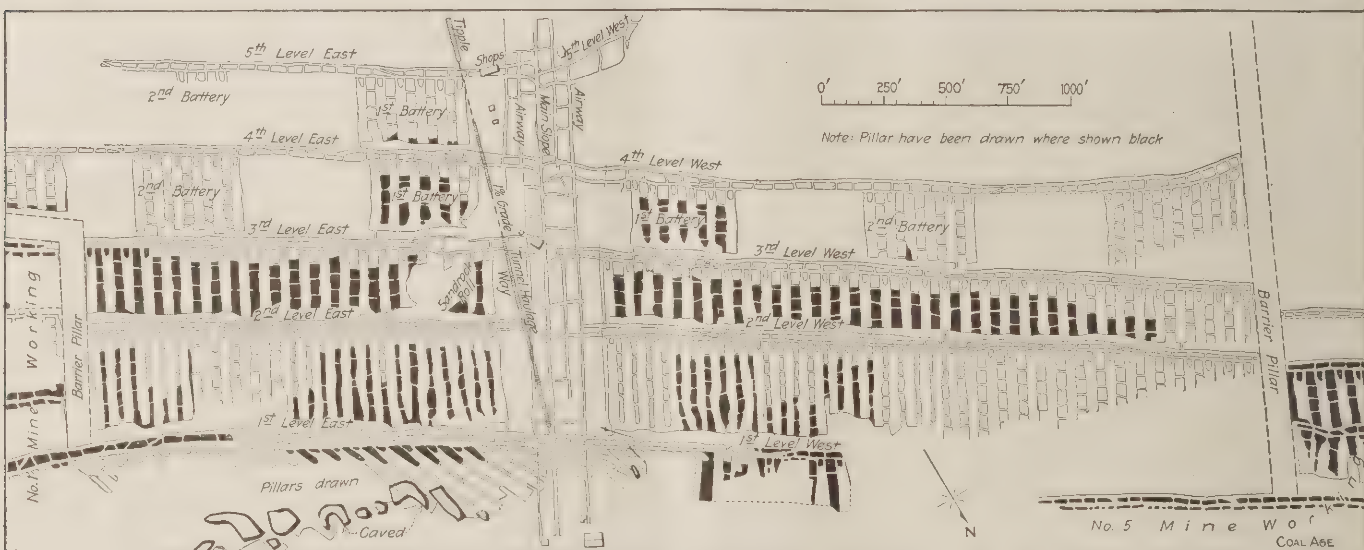
*Department of Mines, University of Washington, Seattle, Wash.

due to the difference of cover or other local conditions.

Crosscuts are driven 6 ft. wide and on 60-ft. centers. Room necks are usually brushed. In single rooms the gob is use wherever the roof is particularly weak. In this system, every alternate 12 rooms are left in as barrier pillars. The pillars in each room are drawn on the retreat back to the gangway; then the blocks are mined and robbed, beginning on the inside. The disadvantage of this method is that it ties up a great deal of coal and requires considerable dead work.

Insufficient pillars and a soft, shaly bottom rock have caused squeezes in some of the older sections. Where pillar coal is being recovered, a skip 10 ft. wide is taken along the room and pillar stumps for a roadway, and portions of the pillars are then removed on the advance up to the limit of safe working and the remainder taken out on the retreat.

Coal is mined by undercutting, shearing and shooting from the solid. The mining is done either in the bottom coal above the floor, in the middle coal and



Map of the Northwestern Improvement Co.'s Roslyn Mine No. 7, at Cle Elum, Wash.

Barrier pillars, 100 ft. wide, are established between adjacent mines, and strong chain pillars left to support the entries and slopes. The slope haulageway is usually made the intake and the air course the return. Some mines having three slopes, use the third either as a manway or an auxiliary return.

Room necks are driven 8 ft. wide, 40 ft. long, and both single and double rooms are used. The double rooms are 40 ft. wide, and have two room necks with a 24-ft. pillar between. Pillars between adjoining double rooms are 30 to 40 ft. wide; the general methods of working are clearly shown in the accompanying map. Single rooms under light cover are driven 24 ft. wide and have 20-ft. pillars. There are occasional variations from these general dimensions, packed on one rib and in double rooms it is placed in the center, back of the pillar stumps. For room timbers, 6-in. props are generally used throughout the district, and these are usually spaced 4 ft. 6 in. in each direction. Little timber is required along the entries.

Pillars of from 30 to 50 ft. in width are left between the face of the room and the next entry above. When the roof conditions will permit, rooms are driven up to the limit and the pillars immediately drawn back to the entry stump, which is left until the entry is finished. It is often necessary, however, to leave the pillars standing.

Retreating System

A modification of this method, known as the "battery and block" system, is in parting of the seam, or in the top coal. Occasionally the coal is sheared in the rooms, but this is confined more particularly to the entries. Shooting from the solid is practiced, although the method is not in general favor. Black powder, fired by squib, and Monobel No. 3, fired by fuse and cap, are most generally used. In some of the mines shot lighters are employed, but as a general rule, each miner fires his own shots.

Room Workings

The steepest dip in the field is 30 deg., while the average lowest is about 10 deg. Coal will run in chutes on the higher pitches, and this method is employed when possible. The chutes are of steel plate, 2 ft. wide, in convenient lengths, and are carried in a straight

line from the center of the room necks up to the face. The chutes extend out to the entry, permitting the cars to be loaded directly. "Bucking" the coal is sometimes necessary. Four men usually work in a double room, two on each side.

On the lighter pitches, the cars are taken up to the face of the room by a gravity-plane arrangement. The track along the entry is laid with the low side rail slightly below the other, in order that the cars may ordinarily pass the room switches, which have fixed points. Cars are switched into the rooms by simply forcing the wheels to take a turnout on the high rail. Just inside the neck of the room is another frog and switch with movable latches. One track is carried straight up along the rib and the other parallels it at a distance of 5-ft. centers. These rails above the latches are usually of wood 4x4 in. in cross-section, laid on ties spaced 5 ft. apart.

Near the face of the room, a wheel post is set, to which is fastened a 12-in. sheave. The rope is given a turn around the sheave and one end connected to the load at the face, and the other to the empty at the bottom of the room. In this way the full car going down brings up the empty. The sheave is usually spragged by means of a wooden pin, and there are few runaways. The descending car always throws the latches, so that the next car will take the right track. Excess rope is coiled up and lengthened as required. Instead of having two tracks in each room neck of a double room, one track may be laid in each room and the rope passed over two sheaves at the face of the double room. This also requires a reversed or back switch on the main entry.

View Showing Underground Haulage Turnout

Platform at Bottom of Chute

Ventilation and Lighting

The hill workings are usually free from gas and dust, but the dip workings in many cases have both. Several explosions and local fires have occurred in the past. All mines are ventilated by surface fans, assisted in some cases by underground "boosters." Many different types of fans are in use, both steam and electric.

The main haulageway in the slope mines is usually the intake, and the air is split at each entry, passing to the face by way of the top entry, and back to the return by way of the bottom entry or air course. Brick and wood stoppings are used, and overcasts are of wood, brick or concrete. In some of the mines, spraying is employed to lessen the dangers due to dust, and in one of the properties exhaust steam is turned into the intake. Slopes and entries are usually kept well cleaned.

Open lights are used wherever possible. The acetylene lamp is in high favor and seems to be displacing the oil lamp. Wolf safety lamps are used in gaseous workings, and electric lights to a limited extent at landings, pump rooms and the like.

Electricity is used entirely for signaling. In one of the mines, a return system is employed, in which hoisting signals ring at each level simultaneously with those in the engine room. Many of the mines have installed telephones.

As a rule, the mines are not very wet and electric pumps of the centrifugal and plunger types are most commonly used. These are generally run in relays on 500 volts, direct current.

Surface Equipment

The surface equipment at most of the mines is very simple. The boiler and engine house, office, shop, and powder house, together with a simple tipple, make up the usual arrangement. The power plant, steel headframe, and tipple at the Roslyn shaft are the most pretentious structures in the entire district. Timber construction and housing of galvanized iron are uniformly used throughout the district.

The machinery and equipment are without exception uptodate and efficient. The N. W. I. Co.'s plant at Roslyn furnishes light and power for the mines in the upper part of the field; secondary plants, coupled in parallel with this at the lower end, supply the light and power around Cle Elum. Practically all of the tipple machinery in the field is electrically driven, and in a great many cases electric hoists are in use.

Coal is shipped to market as it comes from the mine without any further preparation than screening. Some picking is done in the mine whenever sulphur balls are found. The coal mined by the Northwestern Improvement Co. is used by the Northern Pacific locomotives and is not even screened before loading. The other mines in the district which supply the outside markets, screen the coal. Three types of car dumps are in use, the pushback or horn dump, the crossover, and the cradle. Some car pushers and return cars hauls are used and only one plant, the Beekman, has shaking screens; all the others have the usual stationary bar screens. The prepared sizes are run-of-mine, lump, steam and egg, and the sizes of these grades vary.

The rock and waste which come to the tipple, are usually dumped into rock chutes and loaded into 3-ton side-dump cars which are hoisted by a rope over a bull wheel at the top of the rock pile where a tripper automatically opens the car doors and discharges the material.

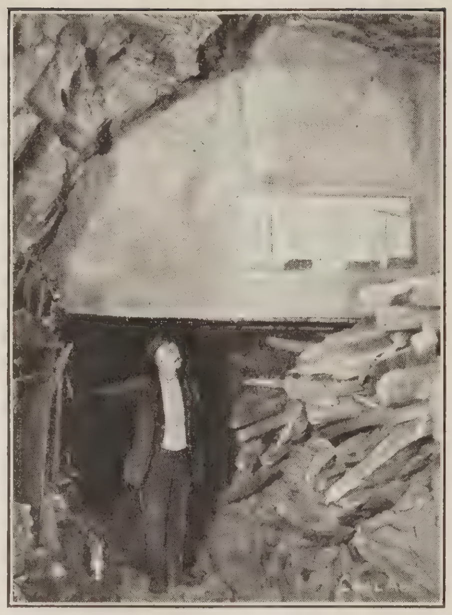
Labor

The labor around the mines is made up of English and Scotch miners, together with Italian and other Southern European races. In the early days of the district negroes were brought in to break a strike and since then there has always been a fair proportion of these among the mine workers. The miners are organized under the jurisdiction of the United Mine Workers of America, and are now working under the terms of a 2-year agreement which expires in September, 1912. In 1910, there were 1687 men employed on inside work and 300 on outside work at the various mines in the field. Ten fatal and 48

nonfatal accidents occurred during the year.

The mining towns through the field are cleaner than those commonly seen in other parts of the country. Many of the men own their own homes, and there are no dry houses at the mines although one is maintained at the Y. M. C. A. building in Roslyn. This institution is supported by both the company and the men. The miners also maintain a hospital and staff of doctors. In the past, the company has adjusted all damage claims directly with the men but under the new liability law in the state, they now contribute a certain amount which is used to pay out injury and death benefits.

The Northwestern Improvement Co. and the Roslyn Fuel Co. each maintain rescue apparatus and rescue squads. The former has six and the latter three sets of Draeger apparatus. At the first aid meet at Pittsburg last fall, exhibitions were given by a squad sent by the Northwestern Improvement Co.



Concrete Overcast with Explosion Door

Wage Scale

The scale of wages paid in the field is fixed by the agreement between the workers and the operators. Miners, timbermen, and tracklayers are paid $3.80, shot lighters, $3.95, motormen, drivers and rope riders, $3.35, engineers and cagers, $3.40 and helpers $3.15. The rates for contract workers per long ton are 92c. for chute work, 95c. for ordinary room work where the cap rock is left up, $1.02 where 12 in. or less of cap rock is taken down, and $1.05 where more than 12 in. of cap rock is removed. Yardage prices paid for driving entries 14 ft. wide are $1.85 when the cap rock is left up, and $2.90 when brushed; 8-ft. entries are $3.40 per yd. Slope sinking is $3.70 and crosscuts in rooms $1.15 per yard.

The average cost of production for coal delivered on cars at the tipple is probably between $1.15 and $1.25 per ton, including all operating expenses except coal royalty, depreciation and overhead charges. The average value of the coal at the tipple is in the vicinity of $2.50, the average figure for all mines in the state in 1910 being $2.57½.

The Roslyn district is at present the largest and most consistent producer in the state. In the older workings, pillar coal is being recovered, and in the new mines, the improved methods are yielding increased percentages. In addition to this, there are many hundreds of acres of virgin coal awaiting development. It is safe to predict that the Roslyn field will continue to be the leading producer in Washington for many years to come.

West Virginia Mining Accidents

By F. C. Cornet*

A presentation of some interesting and comprehensive data regarding accidents in the West Virginia mines. The author concurs with Chief Inspector Laing in the view that safety will be obtained only by constant and close supervision. As compared with the Belgian mines he is of the opinion that the West Virginia operations are much the safer.

Statistics published by the State Mine Department show that during the fiscal year ended June 30, 1910, the average daily tonnage for each man employed inside was 4.21 long tons. Taking the whole United States, the corresponding average is 3.25 tons.

During the period considered there were killed inside the West Virginia mines, 56 men out of each 10,000 employed, as compared with 38 for the whole country. In Belgium, where the average daily output per man is one-half ton, they kill only 10 men out of each 10,000 employed.

From a long personal experience in both countries, considerng natural conditions alone, I am of opinion that the coal mines of West Virginia are immensely safer than the Belgian mines, which have the deserved, if unenviable, reputation of being the most dangerous in the world.

From the figures given above some would be inclined to deduct that, fatalities being less numerous where the average tonnage is smallest, the larger number of fatalities is the result of a greater rush in getting coal out. Nothing would be further from the truth. From personal experience I know that our West Virginia miners do not exert themselves harder to get out 4.21 tons of coal per day than do their Belgian brothers who produce only one-half ton.

*Mining engineer, Charleston, W. Va. Note—Abstract of paper read before the West Virginia Mining Institute.

The reason why they get out more coal on this side of the Atlantic depends 75 per cent. on better natural conditions, and 25 per cent. on the Belgians; for safety reasons, their laws prohibit using mechanical devices and appliances, without which most of our West Virginia mines could not be operated at all, notwithstanding their incomparably better natural conditions.

Accidents Caused by Falls

As in all other coal-mining countries, the largest number of fatalities in West Virginia is caused by falls of slate and coal. During the fiscal year ending with June, 1910, out of a total of 307 men killed inside, 215, or 39 out of each 10,000, were killed under falls.

This bad showing is hard to explain otherwise than by the victims' own carelessness, which accident reports bear out. It cannot be said that the mines where these accidents occurred had bad roofs. In fact, nearly all of said mines were reported as having fair roofs. Nor were the majority of those killed by falls green men; only 75 fall victims are reported as having had less than five years' experience in coal mines, while 94 had an experience varying from five to 40 years. Forty-six were so little known to the mine officials and others that the amount of experience they had could not be ascertained. I do not think I will be far wrong if I assume that one-half of these men had less than five years' experience, and the other half more than five years. That would make a total of 98 men killed who had less than five years' experience, and 117 who had not more than five years. Do not these figures show that greenness, or ignorance of mine work, is not at the bottom of the trouble?

Insufficient supervision on the part of mine officials and absence of discipline on the miners' side—the latter being a direct result of the former—are responsible for at least 75 per cent. of the deaths by falls. I fully agree with John Laing, chief of the mining department of

the state of West Virginia, who, in his report for the year ending June 30, 1910, states that operators should supervise their mine closely and every minute, day and night. Do not let anything escape observation and enforce rigid discipline.

The trouble is that in many mines too much is expected from the foreman. In the large mines it is seldom that the foreman has enough assistants to properly cover and police the workings. I have known mines where it was a physical impossibility for the foreman, no matter how good a walker he was, to see every place, on an average, more than once a week.

Foremen, as a rule, mean well, and are perfectly alive to their responsibilities. As a rule, also, they are handicapped by a lack of assistants. They should have enough assistants not only to inspect every place once a day, but oftener if necessary; that is, if safety to the men demands it. Safety, sometimes, may demand that an assistant foreman be left permanently for some length of time at one place or another in order to insure the carrying out of some order of the foreman.

It is all very well to say that if a man obeys orders only when watched by another he ought to be discharged; but it is a fact that very few men nowadays will allow themselves to be moved by fear of being discharged. Men are scarce. Nobody knows it better than the men themselves, unless it be the mine foreman. If a man is discharged he gathers up his tools and walks to the nearest mine, often a short distance away, where the foreman will be glad to give him a job without asking questions.

Haulage Accidents

During the year ended June 30, 1910, there were 56 fatal accidents from mine cars and motors. This is a large number, being equivalent to 10 out of every 10,000 employed. In this case, also, an examination of the accident reports shows conclusively that most of the casualties are due to the victims' own carelessness.

This carelessness, no doubt, was aggravated by insufficient supervision. It is the same old story we have discussed previously. In this case we see miners riding to work or going home in cars or on motors, trapper boys jumping between two cars of a fast-moving trip in order to get a ride outside and reach home sooner. We see motormen and drivers driving at reckless speed, and also drivers riding on the front of cars, their legs swinging on one side and forgetful of the fact that it is on that side that there are a few places where the car clears the ribs by one-sixteenth of an inch, or less.

Are not these things familiar to many of us? Of course, there should never be any such tight places for drivers, or anybody else, to be caught in. That shows negligence on the foreman's part. It is a fact, however, that many such tight places could easily be found in many mines. There is no excuse for them. Manways, wherever practicable at all, should be provided. Where the operator has not provided any, and the men must use the haulage as a traveling way, the law should always be complied with, and regular refuges, duly whitewashed, provided. There are still haulages used as traveling ways on both sides of which the gob of many years lies piled several feet high, making escape difficult for those who happen to meet a trip in such a place.

There is also too much wildcatting of cars. It is not only a dangerous practice, but a costly one. In many instances it could be dispensed with to the pecuniary benefit of the operator, not to say anything of safety. Not only would it save life, but it would soon pay for itself in reduced wear and tear on the cars—the car wheels principally—cut down track repairs; and less coal would be lost from the cars. This coal, if not gathered daily—which is seldom done—is soon ground to dust and, in many mines, becomes a permanent source of great danger. There cannot be doubt in anyone's mind, after reading the accident reports, that the majority of haulage accidents are caused by the victim's own carelessness.

Electrocutions

During the year ended with the month of June, 1910, a total of 18 men were killed by electricity. Of these 15 were killed by a voltage exceeding 500, while only three were killed by a current not exceeding 250 volts. Not more than one-fifth of the mines in the state carry the higher voltage. They caused, however, five-sixths of the electrocutions, as against one-sixth chargeable against the lower voltage. In his interesting report for the year ending with June, 1910, Mr. Laing, calling attention to the subject, writes as follows:

> An electric current carried in a mine exceeding 300 volts is unnecessarily dangerous to life and limb, and no pecuniary consideration should ever be offered in extenuation of perpetuating methods that have resulted in such a sacrifice of human life.

The figures given above certainly justify Mr. Laing in his views. There are, however, several ways by which the fatalities from electricity could be notably reduced, and they apply to any kind of voltage, high or low. The trolley wires, very often, are not installed properly, the idea being too often to economize on the first cost without thinking of the future cost of maintenance. The wire is either too low or not far enough to one side of the track, no matter whether the road is a traveling way or not—which it often is. The hangers are often too far apart, and the wire sags too much.

The mines having manways are at a decided advantage when electricity is a factor. In such mines the men have no business near the trolley wires. When any kind of electric wire, no matter what the voltage or purpose, is run along a manway it should be protected by a durable shield made of boards running parallel with the wire.

Manway or not, all miners should be cautioned against carrying any auger or bar of any kind on their shoulders when in the vicinity of a wire, unless protected by wooden shield as just mentioned. It does not make any difference if the wire is insulated, because the best insulation does not keep in a mine.

The motors should always be kept in prime condition. This is practicable, and will go a long way toward avoiding dangerous, even fatal, shocks; for it will save the motorman many an occasion of tinkering with his motor, which too many motormen have a tendency to do, under pretense of effecting repairs.

With the wires and motors in perfect shape many causes of mortal and other shocks will be eliminated. There will also be fewer causes of short-circuitings or grounds. All this is perfectly practicable, and is the best paying way of dealing with electricity in coal mines; at least it is my experience.

Miners should never be allowed to ride on cars going to or returning from work. A man getting on or off a car on the wire side is very likely to receive a shock. Where there are no traveling ways, the men having to travel on the electric road, the wire should always be on the opposite side from the refuge holes. The place should also be well drained; for if the road is wet, or simply muddy, the men trying to dodge bad spots may come in contact with the wire.

Gas and Dust Explosions

With the exception of one solitary death from a gas explosion, the year ending June 30, 1910, so far as gas and dust are concerned, was a very fortunate one, following, as it did, two most disastrous years, during which 518 miners were killed by explosions of those two dangerous agents. These explosions had stirred public opinion to a high pitch. Then, for a whole year, the operators' vigilance, assisted by the untiring efforts and devotion to duty of the whole Department of Mines, were successful in keeping down the monsters. These, however, soon broke loose again in different parts of the state, each time making numerous victims.

For a period of 14 years, ending with June, 1910, explosions of gas killed 128 miners, while those dust-killed were 484. Comparing these figures with the number of men working inside, only 2.43 miners out of each 10,000 were killed by gas during the period considered, while 9.23

out of each 10,000 were killed by dust explosions.

It is readily seen that dust is by far the more dangerous agent, in a ratio of nearly four to one. Gas and dust taken together, during this 14-year period, were responsible for a total of 612 deaths, a proportion of 11.63 victims for each 10,000 employed inside the mines—much less than were killed by falls, but a great many more than are killed from all causes in the coal mines of Belgium. The latter are often 4000 ft. deep, and sometimes deeper. They depend for their coal on seams averaging hardly 2 ft. in thickness. These seams are sometimes as thin as 12 in. As a rule, the seams are faulty and pitch strongly. Sometimes they are vertical, or even inverted. Most of these seams are extremely gaseous. With very few exceptions all are dry, and an abundance of dust is a constant source of great danger.

In West Virginia we work on the room-and-pillar system, insuring ventilation from place to place by means of crosscuts, the maximum distance between crosscuts being fixed by law at 80 ft. If there is enough air in circulation and there is a crosscut right at the face that room may be what is called ventilated, but its face will not be swept in its entirety by the ventilating current. The corner of the room further removed from the crosscut will hardly be touched by the air, as is easy to ascertain experimentally.

Ventilation

If the seam liberates gas in any quantity a sweeping of the whole face by the ventilating current is the only thing that will remove gas in a positive manner. However, I am disposed, for an instant, to admit that when the crosscut is at the face the place is, for all practical purposes, sufficiently ventilated; but suppose the crosscut is 10 or 15 ft. behind the face? Then, I contend that, if the place liberates gas, it is not safe any more, no matter how much air runs through the last crosscut.

The weakest point about our ventilating system, is that, in a case when there is gas at the face, we depend on a fireboss to discover it. He may discover it in time, and condemn the place pending the building of a brattice; but, as our fireboss is a human being, he may err. He may not discover anything; he may even omit to visit the place, thinking that, since there has never been any gas found in it there is no use inspecting it any more, and pass the place as safe. The miner will walk into it a few moments later and ignite the gas. The chances are he will not live to tell about it. If there is dust lying around, the conditions are favorable for an explosion that may involve the whole mine and kill all the men in it.

Our ventilation system involves the sending of a man, or several men, to visit all the places to see if they are safe before the miners go to work. Ventilation in order to be safe must be positive, automatic, and sweep all faces as they advance, regardless of any inspection or brattice. With our room-and-pillar system such ventilation is not practicable.

In our best ventilated mines there is always a possibility of a place filling up with gas from the face down to the last crosscut. A body of gas thus formed may get ignited in the place itself, or it may reach the other places beyond, being carried there by the air current, and be ignited at any point. The body of gas may be large enough to cause considerable damage by itself if exploded; but if the explosion is propagated by dust, results may be a great deal worse. Automatic, positive ventilation would not allow of the formation of such bodies of gas. It removes the gas, particle by particle, as it comes out of the coal, sweeping it away, too much diluted to do any harm. With our present system of ventilation gas may be present in a gaseous mine at all times in some part or other of the workings.

Gaseous Mines

In a gaseous mine there is always present the great danger of small amounts of explosive gaseous mixtures getting ignited, from one cause or another. It does not take much gas to create, by explosion, such a big commotion as will be felt strongly in remote parts of a mine, raising clouds of dust in a hundred places.

A gas explosion, even of small proportions, may thus not only raise hundreds of dust clouds, but ignite as well the nearest of them. The inflammation, then, will run from dust cloud to dust cloud, creating a rapid succession of explosions, wrecking and killing everything in its path.

We may succeed, in our mines, to reduce the danger from gas and dust to a minimum, but we shall never be able to free them so completely of both these elements of danger as to be justified in disregarding them entirely. After taking all precautionary measures against gas and dust, it will be just as important to take such measures as will banish all causes of inflammation of either gas or dust.

In mines generating gas in appreciable quantity there is no place for naked lights. Electricity should not be used near the faces. All places should be cut by machine, in order to reduce to a minimum the chances of solid shooting.

Nothing but approved safety explosives should be used, bearing in mind that the safest of explosives ceases to be safe when more than its charge limit is used in one hole. This is too often forgotten by miners.

It should never be permitted to fire more than one shot at a time. When several shots are fired together, or in rapid succession, it is easy to understand that gas might be liberated and dust raised by the first shot and ignited by the next, even when safety powder is used.

Notes on Shooting

By all means the use of fine coal should be rigidly prohibited for tamping purposes. Before shooting the place should be tested for gas. When a mine is only dusty, and not gaseous, there is no danger from the ordinary naked lights, such as used by miners; nor is there much danger from electricity.

Of course, all places should be cut by machine, and solid shooting strictly prohibited. Explosives and shooting rules, the same as in gaseous mines, as described above. All these recommendations to minimize danger from gas and dust will go amiss if not carried out to the letter.

Miners, if left to themselves, have a tendency to revert to some more familiar explosive, like black powder. The miners would also be prevented from using too large quantities of explosive in one hole. This is an important thing, as the so called safety explosives are not safe if more than their charge limit is fired in one hole. We have all noticed the tendency of the average West Virginia miner to use absolutely too much explosive in his shots. That would not do with safety powder.

No large quantity of explosive should be carried by any one man, and no quantity of explosive, no matter how small, should ever be hidden away in a receptable, such as a box or a can. It would be well to remember that the most disastrous mine explosion in history, the dust explosion at Courrières, France, four or five years ago, was started by the accidental explosion of less than 2 lb. of a safety explosive, called "Favier," which had been hidden in a ventilation pipe of galvanized iron 20 in. in diameter. In this case there was no gas at all to help the explosion at the start; but there was dust aplenty. That dust explosion at Courrières killed more than a thousand men.

It will be remarked that I have not insisted on the ways and means of keeping down gas and dust. That is pretty well understood by all coal-mining men in our state. What is not so well understood, I believe, is the importance, just as great, of keeping out of our mines all causes of inflammation of gas and dust, even after we have done all that can possibly be done otherwise to remove danger from both sources. On this I have insisted at some length.

Points in Mine Ventilation

By J. T. Beard*

A multiplicity of theories involving some popular fallacies in mining textbooks. Misconception in regard to the diffusion of gases in mines. The limit of diffusion of gases. Detection of carbon monoxide in mines not made by observing lamp flame. Mistaken relation of pressure and power by early writers. Manometric efficiency, a useless term in comparing fans.

What we do not know about mine ventilation would perhaps make a larger book than the facts we know. It is often bewildering to find how limited is our knowledge of actual facts relating to coal mines and we are simply lost in the multiplicity of theories that are urged to account for the clearly observed phenomena of mining. Some of these theories are based on sound scientific principles while many others are pure speculation, having no foundation other than exist in one's imagination. While some of these theories, though useless, are equally harmless, others lead to dangerous practices in the mines that are not infrequently responsible for the loss of lives and property.

So great is the horror of mine disasters in which the mine may become a living tomb, that men charged with the responsibility of mining operations are often willing to accept and too prone to adopt any theory that has a semblance of plausibility. The present paper will confine itself to a brief discussion of a few of the fallacies that have crept into our knowledge of mine gases and the practice of mine ventilation. Mining textbooks are largely responsible for many of our misconceptions with respect to mine gases. They describe the physical properties of the gases commonly found in mines. The properties described, however, are those of the pure gas, such as methane or marsh gas, carbon dioxide, hydrogen sulphide, etc., as determined in the laboratory. Inasmuch as these gases never, we may say, occur pure in the mine, but are mixed in various proportions and diluted more or less than normal percentage of oxygen, it is easy to see that the mixed and generally diluted gases of the mine will possess properties that often differ widely from those described in the books. Too much emphasis has been placed on these physical properties and not enough on the behavior of the gas or gases in the mine.

Diffusion of Gases

The question of the diffusion of gases furnishes a striking example of the misconception that often exists in the practical mind, growing out of the failure of textbooks to properly treat the behavior of gases in mines. In these books diffusion is described as a rapid and intimate mixing of two or more gases. This is true, but the definition is not complete unless it states that the mixing is *uniform and in fixed proportions.* We often confuse *diffusion* with *mixing,* whereas the two processes are widely different. Gases *mix* together *in any proportion* and the mixture is not uniform, except as diffusion tends to make it so after a brief time. Diffusion, on the other hand, acts according to a fixed law, which is stated as follows: The rate of the diffusion of each gas is inversely proportional to the square root of its density.

[Note—Paper read before Summer Meeting, West Virginia Coal Mining Institute, Charleston, W. Va., June 6, 1912.]

This law of diffusion gives a definite mixture of the gases, providing the diffusion is complete and no other action occurs tending to mix the gases. It is interesting to know, in respect to the diffusion of marsh gas and air, that the specific gravity of marsh gas (CH_4) being 0.559, its square root is 0.748, or, say ¾, which makes the inverse ratio, in that case, $^4/_3$ and shows that the diffusion of marsh gas into air would produce a mixture consisting of four volumes of gas to three volumes of air. This mixture would have a specific gravity of

4 vol. CH_4,	relative weight, $4 \times 0.559 =$	2.236
3 vol. air,	relative weight, $3 \times 1.0 =$	3.0
7 vol. mixture, relative weight,		5.236

$$sp.gr. = \frac{5.236}{7} = 0.748$$

This mixture would be very "sharp" since it contains

$$\frac{4 \times 100}{7} = 57 + \textit{per cent.}\ CH_4$$

Its specific gravity being less than one, if undisturbed, it would collect at the roof, or at the face of a steep pitch.

The practical point to be noticed is that when marsh gas issues from the roof strata or from the coal face on a steep pitch, it is possible for this mixture to form and be mistaken for pure marsh gas. The question is often asked, "If the diffusion of gas is rapid, how is it that "sharp" gas is frequently found at the roof while the air below is practically free from gas; why does not this gas diffuse and fill the entry?"

To answer this question from a mining standpoint, it is necessary to remember that the very fact that there is a thin layer of gas at the roof and practically no indication of gas below, shows a uniform or undisturbed condition of the atmosphere. It is also necessary to note that as diffusion advances the density of the mixed air and gas rapidly approaches that of air; and when this point is reached further diffusion ceases. In plain language, the pure gas issuing from the strata is so rapidly diluted with air that diffusion practically ceases a short distance from the point of issue. The action is continuous for a depth below the roof, depending on the quantity of gas given off per minute, per lineal foot of entry, and the volume of air passing in the entry. The point to be borne in mind is that with a certain emission of gas from the roof per lineal foot of entry and a certain volume of air in circulation, diffusion is most rapid close to the roof and decreases in rapidity downward, each successive layer of air containing a less and less percentage of gas as the density rapidly approaches that of air when diffusion practically ceases.

Indications of Presence of Carbon Monoxide in Mine Air

In describing the effect of carbon monoxide on flame all textbooks mention particularly the increased brightness and the lengthening of the flame, due to the presence of this gas. It has been suggested, very properly, that this statement is misleading and may be the cause of many a miner losing his life in the attempt to rescue others after an explosion. This is true. It would be fatal to enter an atmosphere more or less charged with afterdamp, and depend for safety on the indications of the flame of a safety lamp.

It is true that a lamp flame is visibly lengthened and brightened in an atmosphere charged with the fine dust of an inflammable coal, which, in contact with the flame of a lamp, generates carbon monoxide that is burned at once on the surface of the flame to carbon dioxide. In this case, however, the gas is not present in the air, but is generated by the burning of the dust in contact with the flame. The same indications occurring in an atmosphere of afterdamp free from dust, would be accompanied with surely fatal results.

When it is remembered that carbon monoxide has the widest explosive range of any gas except hydrogen and that its lowest explosive limit is marked by a percentage of only 13 per cent., and its inflammable limit is still lower, probably less than 2 per cent., while ½ of 1 per cent. of this gas is fatal to life, it will be seen that it would certainly be fatal to depend on any indications of the flame of a lamp to warn one of the presence of this gas in the mine air, because the

indications would be observed too late, if at all.

Some surprise may be expressed that miners have been burned by this gas collected behind a standing shot when they have thrust a lamp into a crevice behind the coal to examine the effect of a shot, and yet have not been killed by the poisonous qualities of the gas. This is due, however, to the rapid diffusion of the gas exhausting itself a short distance away, by the equalizing of the densities of the gas and air, as previously explained. The percentage of gas falls below the fatal mark, a short distance from the place where it is formed.

Pressure and Power in Ventilation

In the early history of mining, ventilation was secured wholly by natural means or by the furnace. The basis of calculation was the motive column or ventilating pressure due to the difference in temperature of the upcast and downcast shafts. Little was said of the power producing ventilation. Later, when centrifugal fans came into general use as mine ventilators it was seen that either the power applied to the fan shaft, or the net power on the air, was the true basis of calculation.

The early writers on mine ventilation, Atkinson and Fairley, were good as far as they went; they were indeed remarkable for their clearness and simplicity. But as the theory and practice of ventilation became better known it was found that the old rule, *"Pressure varies as the square of the quantity of air in circulation"* was only true when speaking of a given mine or airway. But, when speaking of a constant power, the pressure varies inversely as the quantity of air circulated. For example, to double the quantity of air in an airway will require four times the pressure; but in order to obtain double the quantity of air with the same power, the pressure must be reduced to one-half the original pressure.

There are other important points that the early writers did not explain. They failed to give the mine its proper value and to make clear the fact that it is the mine resistance that establishes and determines the pressure, which the ventilator creates. The same fan run at the same speed and consuming the same power will yield a different quantity and pressure operating on different mines Keeping the power on the fan shaft constant, and turning the fan at practically a constant speed, as the pressure against which the fan operates is increased, the quantity of air is decreased; and *vice versa,* a decrease of pressure gives an increase in the quantity of air delivered.

If this is true it is plain that what has been termed the "manometric efficiency" of a fan does not describe the fan; because it is the ratio of the actual pressure developed to the theoretical pressure as determined by the formula.

For pressure, in pounds per square foot,

$$w.g. = \frac{12 \times 1.2}{1000} \; \frac{u^2}{g}$$

For water gage, in inches,

$$p = 0.002\, u^2$$

in which u = tip speed of fan (ft. per sec.).

If the mine resistance determines the actual pressure then the manometric efficiency describes the efficiency of that particular fan working at that particular mine and no other. At another mine, the same fan would show a different manometric efficiency. The term is, therefore, useless in comparing fans to determine the best type of construction. Fans must be compared on a basis of power, which determines the mechanical efficiency of the fan. This term properly describes the fan, being independent of the mine or the resistance against which the fan is operated.

There are numerous other points relating to fan ventilation that are being studied and revised today. Among these may be mentioned tandem fan installations, high-speed fans, the effect of short-circuiting the air on the speed of the fan; etc. Each of these questions furnishes ample opportunity for discussion that cannot fail to be instructive and to interest all who have mines to ventilate. The discussion of such matters as these often brings to light fallacies that have become deeply imbedded in the mind and which are hard to efface.

Only a few weeks ago one of the leading technical journals of England filled two of its columns in an attempt to prove that the cutting out of the mine resistance, by opening the doors at the top of the upcast shaft would cause the fan to run faster. It is needless to say the argument was based on a fallacy and, of course, proved to be a fallacy.

A short time previous, another fallacy appeared in one of the leading mining technical journals in this country, in the answer to a question asking for the discharge of a 4-in. siphon line rising 17 ft. in 800 ft. and then falling 75 ft. in 300 ft., giving it an effective head of $75 - 17 = 58$ ft., the entire length of the siphon being 1100 ft. One answer gave the discharge as 259 gal. per min., while another made it only 179 gal. per min. The fact is that this pipe would simply run dry in a short time because the atmospheric pressure would only cause a flow of 130 gal. per min. in the 800 ft. of 4-in. pipe, rising 17 ft., while the 300 ft. of 4-in. pipe, falling 75 ft., would discharge 330 gal. per min. under gravity.

This and other illustrations that could be given show the need of a more thorough knowledge of conditions before attempting to work out problems of this nature. The conditions affecting all mining problems are multitudinous and their consideration is important. It is the neglect to properly consider the conditions affecting a problem, that causes the frequent disagreement between theory and practice.

The Carbide Lamp in Mining

One erroneous idea, much needing correction, has become quite prevalent in regard to the carbide lamp. It is often asserted that this lamp will burn in an atmosphere of carbon dioxide (CO_2); that it is not dependent for its combustion on the oxygen of the air; and this argument has been used to press the claims of this lamp for mining purposes. These statements are both of them wrong. The lamp will *not* burn in an atmosphere of pure carbon dioxide; and it *is* dependent for its combustion on the oxygen of the air.

This is readily seen by writing the equations showing the reactions that take place; first, in the generation of acetylene gas from calcium carbide by the addition of a little water; and, second, in the combustion of the acetylene gas in air, forming carbon dioxide and water vapor; thus,

$$\underset{\text{Calcium Carbide}}{CaC_2} + \underset{\text{Water}}{2H_2O} = \underset{\text{Calcium Hydrate}}{Ca(OH)_2} + \underset{\text{Acetylene}}{C_2H_2}$$

$$\underset{\text{Acetylene}}{2C_2H_2} + \underset{\text{Oxygen}}{5O_2} = \underset{\text{Carbon Dioxide}}{4CO_2} + \underset{\text{Water Vapor}}{2H_2O}$$

It is readily understood that the acetylene gas generated in this lamp by the action of water on calcium carbide requires oxygen for its combustion and it can get this oxygen from no other source than the air.

What has led to the statement that the carbide lamp will continue to burn in an atmosphere of carbon dioxide is the fact, observed in mining, that the carbide lamp is not extinguished in blackdamp when other lights fail to burn. This is true; the carbide flame, like the hydrogen flame, is more tenacious than other flames. The hydrogen flame requires 4 times as large a percentage of CO_2 in the air for its extinction, as is necessary to extinguish an ordinary light; and the acetylene flame of the carbide lamp is similar in this respect.

It is a common mistake among mining men, who generally know better, to call blackdamp, carbon dioxide, whereas the blackdamp of mines is a variable mixture of air and extinctive gases consisting largely of carbon dioxide. It is possible for the carbide lamp to burn in this mixture because the mixture contains some available oxygen that supports the combustion. In this respect blackdamp is very different from an atmosphere of carbon dioxide, which contains no free or available oxygen. The carbide lamp, or any other flame dependent on oxygen for its combustion, would be extinguished in pure carbon dioxide.

In this connection, it is important to remember that the carbide lamp will burn in an atmosphere containing over 50 per

cent. CO_2, while 18 per cent. of this gas in the mine air may produce fatal results when breathed a short time. On this account, the carbide lamp is not a safe lamp to use in mine workings generating much blackdamp, any more than the electric lamp is safe in mines generating marsh gas. The lamp does not give sufficient warning of the danger to which the mine worker is exposed. The first intimation he has of the danger comes in the effects produced by the gas on his system; and these may prove fatal before he is found and removed.

I have tried in this brief way, to point out a few of the flagrant errors that exist both in the too generally accepted theories of mining as well as in the minds and practice of many good mining men. If the discussion of these points serves to impress the several fallacies on our minds, the paper will have accomplished its purpose.

Successful Store Management, in Relation to Coal Mining Communities

By Charles H. Lantz*

In nearly all mining communities will be found what is commonly called the "company store." This is a store owned by the mining company, or by a separate company with interlocking directors, organized and conducted to serve the employees of the operating company. The "company store" is almost as necessary from an operating standpoint as the mechanical equipment required for the production of coal, because a mining company without a store is often without men to work the mines.

It is hard to find a class of men who are more open hearted, generous and liberal than those working in and around mines, and their liberality is often to their own detriment, for in times of slack work or other reverses they are not financially able to meet their needs. Nearly every miner knows from experience how difficult it is to enter a community, served only by independent stores. He finds that credit is refused him on account of his being a stranger, and also because irresponsible persons in the past have failed to liquidate their obligations. While independent stores, as a rule, are liberal with their credit, they must at least confine it to people with whom they are acquainted.

In entering a community served by a company store the mine worker is advanced the amount necessary to purchase tools, or is at least told where these can be borrowed until such time as he is able to purchase them. The amount necessary for his maintenance can be drawn daily from his wages, and if married he can purchase the necessary furniture for housekeeping by means of small monthly payments and at no increase in the original price. He is made to feel at home in the store, is treated courteously and helped to know his fellow workers, for there is no other place where the men meet more frequently than in the company store.

In answer to the question: Does he pay more for these advantages and privileges than if it was not necessary for him to obtain them? I would say that in the case of a well managed company he does not. The successful store company must serve its patrons properly, and in order to do this must have a policy of conserving and improving its facilities for the economical handling of business.

The successful company has good credit whereby it purchases all merchandise at the most advantageous figures. It has a system of credits whereby the losses are almost *nil*, and the customers are not required to pay for the bad debts of other patrons. It sells only the best of merchandise; otherwise it would not be a successful company, and for the same reason, it uses standard weights and measures, giving as much as it can, instead of as little as it can, for the dollar. It has a volume of business that turns the stock rapidly, always insuring fresh merchandise, and at the same time reducing the selling cost. This allows the company to obtain a smaller profit than its competitors on individual sales and still make a good showing.

In a community where there are a number of stores of various kinds, which of necessity reduce the volume of business that each can obtain, with attendant increase in expenses, it is not reasonable to expect that the patrons of such independent stores can get the service, quality or just treatment that they receive at the hands of the successful company store.

It is not claimed that capital will be invested except with the expectation of profit, for profit making is the basis of individual and national prosperity. In organizing the store company, the holding company has a right to obtain revenue from it, but by using economical methods, the store can be made the source of such revenue, and at the same time distribute its merchandise to the advantage of the citizens of the community which it serves.

Since both the mining company and the store company are striving for one end—the success of the companies as a whole, without which the community must of necessity suffer, there should be a pleasant and coöperative spirit shown between employees of both departments. Loyalty to the company of which they are a part is essential to their mutual success.

The store company that serves the community faithfully and efficiently, cannot help but be successful and will eliminate all adverse criticism. By a study of the form and methods of the successful companies it will be found that they adhere to a just and equitable policy which not only reflects credit upon themselves but assures a peaceable and satisfied community.

*General manager, Buxton & Landstreet Co., Thomas, W. Va.

Note—Paper read before the West Virginia Coal Mining Institute, Charleston, W. Va., June 6, 1912.

New Geologic Map of Southwestern Pennsylvania

In the extreme southwestern part of Pennsylvania lies an extensive area which is rich in deposits of coal, oil and gas. About 1500 square miles of this region have been mapped by the Geological Survey, the latest contribution to this work being Geologic Folio No. 180, by M. J. Munn. This contains maps and a description of the Claysville quadrangle.

The Claysville quadrangle covers a part of the western portion of Washington County and a small area in the northern part of Greene County. It is underlain by the valuable Pittsburg coal bed, from which the greater part of the coking coal of southwestern Pennsylvania has come.

The geologic maps of this folio show in great detail the position or the "dip" of this coal bed in the entire quadrangle and the depth below the surface at which it may be found. It is believed by coal men that a large portion of the coal in this bed within the Claysville quadrangle has coking qualities.

Other coal beds overlying the Pittsburg coal are exposed at the surface over a large portion of the Claysville quadrangle. These beds, though of poorer quality and in places much thinner than the Pittsburg, may eventually become valuable as the better beds are exhausted. The coal beds of the quadrangle are estimated by the Geological Survey to contain 1,150,000,000 short tons.

West Virginia Examinations

The department of mines, of West Virginia, under the direction of Chief Mine Inspector John Laing, will hold examinations for certificates of competency for mine foremen and firebosses, at the following named places and dates: Welch, July 10 and 11; Glen Jean, July 17 and 18; Elkins, July 24 and 25; Fairmont, July 31 and Aug. 1; Logan, Aug. 7 and 8; Charleston, Aug. 14 and 15.

It is hoped that all mine foremen and firebosses, who are holding positions on the recommendation of their district inspectors, and have not yet secured certificates, will avail themselves of this opportunity, as they will not be allowed to hold these positions after this series of examinations. All others aspiring to the position of mine foreman or fireboss are also invited to take the examinations.

A Ventilating System without Doors

By H. J. Nelms*

The general use of doors in modern mines is gradually being dispensed with, and overcasts used instead. Many systems of mining have been devised to accomplish this, and the one here described embodies some unique and economical features.

*Castle Shannon, Penn.

Where mines generate large quantities of gas, the ventilation is usually the hardest problem to solve. The plan here shown is used in some districts and has been found practicable. It will be noted that no doors are used, the different splits being made by overcasts.

The customary practice in most mines using the three-entry system is to make the middle face entry the haulage road, the one next to the rooms the intake airway, and the other the return. By this system a door is required at all butts, and there are so many reasons why doors are objectionable that a ventilation plan, by which they can be eliminated, is most desirable.

Referring to the accompanying plan, it will be seen that the first and second entries are the intake airways and the third the return. The first butt entry is turned off the middle face entry at 90 deg. and connected with the first face entry by a 45-deg. slant. The second butt is turned square off the third face entry.

Method of Splitting the Air

The air coming in the first and middle face entries is split at the intersection with the first butt, a portion going in the butt entries and the remainder continuing in the main entry. The air enters the first butt entry under the overcast at the intersection of the first butt with the third face entry, travels to the face through the rooms off the butt entry and returns out the second butt to the third face entry. Here it meets the main return from the inside and passes out to the fan.

It is, of course usually necessary to put in regulators on the second butt entry. These latter are usually driven quite wide, about 14-ft., so that the velocity of the air is comparatively low, and much of the explosive dust is deposited. Since the second butt is never used as a traveling way, it may be sprinkled as much as desired, which will greatly decrease the possibility of a dust explosion.

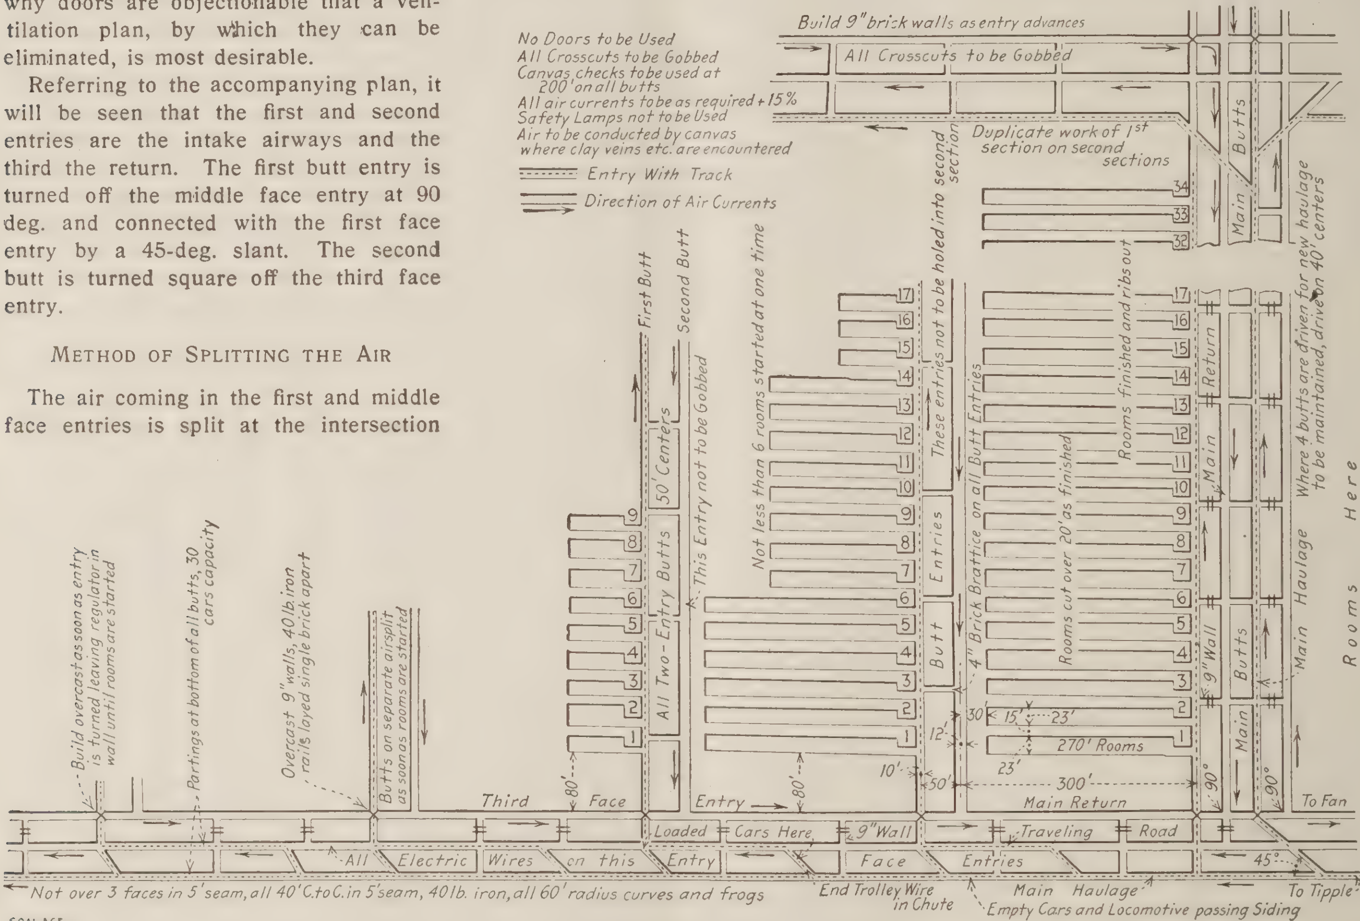
Haulage

The first face entry is made the main haulageway and, at the connection with each butt, a parting is established having a capacity of about 30 cars, which is about the heaviest trip the motors can haul. The motor usually takes 15 cars from two different entries thus leaving this number standing on each parting. The motor going in with the trip runs in on the side track of the butt entry requiring empties, drops 15 cars and then proceeds to the next where the remainder of the trip is left. Coming out it picks up the loads by backing in to the parting in the middle face entry.

Removing the Pillars

The pillars are best removed by cutting crosscuts through the room pillars about 12-ft. wide and leaving a stump of about 5-ft. of coal next to the gob. The stump is taken out as pick coal and this cuts that down to about 60 per cent.; it can usually be mined with little or no shooting.

While this general system of working may appear very expensive at first glance, it has been found highly economical in the end.



Plan of a 2-, 3- and 4-Entry System of Working in which the Necessity of Doors Is Eliminated

---

Ventilation has come to be one of the most important factors in the cost of the production of coal, as the energy of the miners depends in a great measure upon the purity of the air they breathe. Danger from gas explosions is also minimized by adequate air currents. Neglect of ventilation is a standing invitation to increased cost of production.

Central Station Power for Coal Mines

By Graham Bright

Mr. Bright takes as an example, a typical coal-mining installation and figures the comparative costs of central-station and locally generated power, showing the possible saving which may be effected by use of the former. A valuable discussion of data and methods for determining power costs.

Note—Paper presented at meeting of the American Institute of Electrical Engineers, Pittsburgh, Penn., Apr. 25, 1912.

In considering the application of central station power to coal mines the operator of today is sometimes at a loss to know just what saving will be effected, and for the following reasons: First, he believes that he is producing power at a fairly low cost, due to cheap fuel, simple apparatus and low cost of buildings; second, not knowing approximately what his present costs are in detail, he is at first unable to see the saving, if any, as compared with a definite rate per kw-hr. for central station power; third, the use of central station energy often requires the purchasing of new apparatus, and the selling of the present generating apparatus under unfavorable conditions.

In regard to the first reason, the cost of fuel is, of course, low at the mine, but its value should be figured at the price that could be obtained for it if sold. The water question, however, is often a serious one, and bad water in many cases occasions heavy expense for repairs. The boilers, engines and generators as a rule are the simplest and cheapest obtainable, there being little incentive to obtain high economy at a mine power plant. Reliability is the first requisite, and with the class of skilled help obtainable about a mine, this reliability can be obtained only with the simplest kind of apparatus. The buildings are generally of the cheaper forms of construction, and often have inadequate illumination, in which case the equipment does not receive the care it should.

In regard to the second reason, a certain rate per kw-hr. for power from a central station is not always an indication to the average operator as to what his total cost for power and his saving will be.

In regard to the third reason, in order to utilize central station energy it is usually necessary to purchase motors to replace the fan, hoist and compressor engines, and to purchase synchronous converters or motor-generator sets to replace the generators and engines driving them. The boilers, engines, pumps, old generators and piping must be sold and it is rather difficult to get much more than scrap value for these, if they have been in use for several years. If the proper depreciation on the old apparatus has been charged off each year, the value carried on the books should not be very high. The difference between the value of the old apparatus and the salvage obtained for it must be charged off, or the entire value of the old apparatus must be charged off and the value of the new apparatus put on the books as the difference between the cost of the new apparatus and the salvage obtained for the old. To provide for this change, new capital is required, and the members of the average board of directors must be assured of adequate returns before they will permit the expenditure of this new capital.

Method of Determining Comparative Costs for Power

The purpose of this paper is to show a method of determining the cost of power at an average coal mine with its own power plant, and what the cost would be if central station energy were purchased at some definite rate per kw.-hr. The values assumed are only approximate, as it is the method that is to be shown rather than actual values.

We will suppose that we are investigating a shaft mine, having the following list of power apparatus:

TABLE I. POWER EQUIPMENT

4 return tubular boilers, 18 ft. by 72 in. Steam pressure, 90 lb.
2 boiler feed pumps.
1 deep well pump.
1 feed water heater.
1 double balanced steam hoist. Max. hp. of engine, 400.
1 ventilating fan. Horse power of engine, 50.
2 high-speed 150-hp. engines for generators
2 100-kw. 500-volt d.-c. belted generators.
1 10-hp. engine for machine shop.
1 10-hp. engine for screen.
1 25-hp. engine for elevator.
1 5-hp. engine for coal conveyor to boiler room.
2 steam pumps at bottom of shaft, 10 hp. each.

The motors operated from the generators will have a combined capacity of about 500 hp. The generators will be operated about 20 hours per day, the time depending upon the amount of electric pumping to be done. Some of the coal cutting frequently is done at night, which tends to improve the load factor on the generators, the lights and pump load being, as a rule, a small percentage of the capacity of one generator. The hoist will operate 8 hours per day, with an occasional trip at night, or on non-working days. The fan will operate 24 hours per day. The tipple engines will work 8 hours per day, and the steam pumps and coal conveyor will work intermittently.

The mine under consideration has an average output of 1100 tons per day, and operates on an average 18 days per month all the year round. On days that the mine does not operate, one generator must be run to supply power for the pumps, lights and locomotives doing special work.

The operating force will consist of the following:

TABLE II. OPERATING FORCE

1 day engineer for the hoist.
1 day engineer for the electric plant.
1 night engineer for the electric plant.
1 day fireman.
1 day fireman's helper for wheeling ashes and helping around boiler room.
1 night fireman.

The wages of extra repairmen will be included in the upkeep and repair charges.

The amount of coal used under the boilers will be about 500 tons per month, and this coal being slack, or a mixture of nut, pea and slack, its value will be about 50c. per ton. In some plants it is necessary to use run-of-mine under the boilers, in which case the value is considerably higher.

Costs Figured on Monthly Basis

To obtain the cost of power per kw.-hr., it is, of course, necessary to first find out how many kilowatt-hours per day or per month are being produced. It is best to figure the costs on a monthly or yearly basis, in order to take into account the time lost when the mine is not operating. The cost per ton output for power will depend somewhat on the number of days per month or per year the mine operates, since a number of the items of expense go on just the same whether the mine operates or not. In this paper the costs will be figured on a monthly basis, taking the working days as the average per month for a year.

When obtaining the total kilowatt-hours, the load factor should be determined at the same time, since the rate of charge by the central station often depends upon the load factor. The load factor should be figured on the total five-minute, or some other short-time, peak rather than on the capacity of existing machines, since the engines and generators installed are often much larger than necessary, and their capacity is seldom reached by even momentary peaks.

The electrical kilowatt-hours, momentary and five-minute peak loads can easily be obtained by placing a watt-hour meter and graphic recording wattmeter or ammeter in the circuit of the generators for a 24-hour run, both for a working and a non-working day. The power developed by the steam engines driving fans, hoists, etc., is more difficult to obtain. If possible, these engines should be indicated, and from the cycle of operation, the horsepower-hours or kilowatt-hours can be computed for a working and

TABLE III. CAPACITY, KW-HR. AND LOAD FACTORS.

Machines	Five-min. peak	Capacity in kw.-hr., 24 hr.	Actual kw.-hr. for 24 hr.	Capacity in kw.-hr., 30 days	Actual kw.-hr. for 30 days
Generators	150	4,800	800	144,000	19,200
Fan	40	960	680	28,800	18,000
Hoist	60	1,440	336	43,200	6,080
Elevator	20	480	160	14,400	2,880
Screen	5	120	40	3,600	720
Machine shop	5	120	40	3,600	1,200
Conveyor	1	24	8	720	160
Pumps	12	288	120	8,640	2,400
Total	293	8,232	2,184	246,960	50,640

Load factor for 24-hr. working day = 26.6 per cent.
Load factor for 30 days = 20.6 per cent.

non-working day. Where it is not possible to use an indicator, the power taken by the fan engine may be calculated approximately from the size and speed of the engine, steam pressure, size and speed of fan, air pressure, and volume of air in cu.ft. per min. The power required by the hoist can be figured from the work being done and checked by the size and speed of the engine and the steam pressure. It is best to place the information in tabular form, so that ready comparison may be made.

Peak Load on Generators Less than Capacity

Table II shows the method of obtaining the total kilowatt-hours per month and the load factor.

In the first column are listed the various machines that are developing power. The second column gives the five-minute peak load for each machine. It will be noticed that for the generators this peak is less than the capacity, but this is almost universally the case in mine power plants. The fan engine runs at one speed during 10 hours of a working day, and at a speed requiring about one-half as much power for the remaining 14 hours, and for 24 hours of a non-working day.

The hoist has a peak load of about 300 kw. for five seconds, followed by a load of about 150 kw. for five seconds. The average time required for each trip will be about 52 sec., but for intervals of several minutes, this time may be as low as 35 to 38 sec. The five-minute peak is the average kilowatts for five minutes, with the hoist working at its maximum speed. At the average speed, this peak will be about 42 kilowatts.

The third column shows the capacity in kilowatt-hours of each machine if it works 24 hours. The fourth column indicates the actual kilowatt-hours during a 24-hour working day. The ratio of column 4 to column 3 designates the load factor for a 24-hour working day. Column 5 shows the capacity in kilowatt-hours for 30 days, 24 hours per day. Column 6 shows the actual kilowatt-hours for 30 days. This column is made up of the figures of column 4 for 18 days, plus the kilowatt-hours for 12 non-working days. The ratio between the values of column 6 and column 5 gives the load factor for 30 days. The load factor of a mine plant depends largely on the amount of fan and pump load, and may vary from 13 to 40 per cent.

Table IV shows the elements entering into the assumed installation together with the possible savings in these elements when power is purchased.

The interest, depreciation, repairs and upkeep are indicated for each part of the power plant. No saving is figured on the engine building, since it will probably be used for the new motor-generator and switchboard. This apparatus should be so placed that the hoist engineer can look after its operation during the day. For the night shift, a man can be obtained for about $60 per month.

Generators Selected for Peak Rather Than Average Load

In some cases where the generators are modern it may be advisable to retain these generators and purchase motors to drive them. As a rule, the average load on a mine generator is very much below its rated capacity. The peak loads are, however, rather high, so that the generators are really selected in regard to the peak rather than the average load. The type of load curve obtained on a mine generator is shown in some graphic charts in the paper, in the March proceedings of the Institute of Electrical Engineers, entitled "Central Station Power in Coal Mines," by W. A. Thomas. The older types of machines will not stand

TABLE IV. COST BASED ON ONE MONTH OF 30 DAYS.

Items Included in Cost		Total present cost	Amt. saved with purchased power
Three engineers at $85.00		$255.00	*$110.00
Two firemen at $75.00		150.00	150.00
One helper at $50.00		50.00	50.00
500 tons of coal at 50c per ton		250.00	250.00
Oil, waste and packing		50.00	40.00
Boilers:			
Cost, including stack	$4,000.00		
Feed pumps	200.00		
Setting and foundation	800.00		
Feed water heater	400.00		
	$5,400.00		
Interest at 5 per cent		22.50	22.50
Depreciation 7 per cent		31.50	31.50
Repairs and upkeep		50.00	50.00
Insurance		10.00	10.00
Boiler Building:			
Cost $2,000			
Interest at 5 per cent		8.35	8.35
Depreciation at 5 per cent		8.35	8.35
Upkeep and repairs		5.00	5.00
Engines:			
Cost Two generator engines	$3,000.00		
Hoist engine	1,500.00		
Fan engine	600.00		
Elevator engine	200.00		
Screen engine	150.00		
Conveyor engine	100.00		
Pumps	400.00		
Machine shop engine	150.00		
	$6,100.00		
Interest at 5 per cent		25.40	25.40
Depreciation at 6 per cent		30.50	30.50
Upkeep and repairs		30.00	30.00
Building:			
Cost $2,500			
Interest at 5 per cent		10.40	
Depreciation at 5 per cent		10.40	
Upkeep and repairs		5.00	
Piping:			
Cost $1,500			
Interest at 5 per cent		6.25	6.25
Depreciation at 7 per cent		8.75	8.75
Upkeep and repairs		15.00	15.00
Generator, switchboard and wiring:			
Cost $2,460			
Interest at 5 per cent		11.00	11.00
Depreciation at 5 per cent		11.00	11.00
Upkeep and repairs		15.00	15.00
Superintendence		25.00	
Taxes at 1 per cent. of valuation (assessment 90 per cent.)		15.00	7.50
Liability insurance at $1.33 per $100		6.05	4.15
Overhead		50.00	
Total cost		$1,165.45	$900.25
Fixed charges		284.40	
Operating expenses		881.05	

*Provides for attendance at $145 per month.

peak loads much beyond their rated capacity, and even if they would, the engines are seldom in condition to take care of these loads. This characteristic of the engines is really a blessing in disguise for the generators. A modern commutating pole generator driven by an induction or synchronous motor can be purchased to give 100 per cent. overload for short periods with little or no drop in speed and with good commutation. The retaining of the old generator would require a foundation for the motor, a belt, a coupling and probably an extension to the building. The total cost would about equal the cost of a new motor-generator set, while the latter will be a much more satisfactory combination. Synchronous converters are also used instead of motor-generator sets, depending upon the local conditions.

Other Charges

The item "superintendence" includes that part of the salaries of the master mechanic and superintendent chargeable to the production of power at the mine in question.

TABLE V. COST OF NEW EQUIPMENT

1 150-kw. motor-generator set	$2,800.00
1 switchboard	150.00
1 75-hp. induction motor with starter for fan	950.00
1 250-hp. induction motor with control for hoist	2,500.00
1 30-hp. induction motor with starter for elevator	400.00
1 10-hp. induction motor with starter for machine shop	170.00
1 10-hp. induction motor with starter for screen	170.00
2 10-hp. motor-driven pumps	650.00
Installing, including foundation, wiring and buildings	1,000.00
Total cost	$8,790.00

Taxes are figured at 1 per cent. per year, on an assessment of 90 per cent. of the valuation.

Liability insurance is figured on the payroll.

"Overhead" includes that part of the salary of the officers and clerks of the company and of the office expenses chargeable to the production of power, and should be the same proportion of the total overhead charge that the cost of power is of the total cost of production.

The total cost per month is $1,165.45, of which $284.40 is a fixed charge and $881.05 the operating expense. The saving per month with purchased power is $900.25. Since the total number of kilowatt-hours per month is 50,640, the total cost of power per kilowatt-hour is $0.023. The saving with purchased power will be $0.0178 per kilowatt-hour. The difference between these values, or $0.0052, is the common cost per kilowatt-hour, which will exist in either case.

Cost of New Equipment

In Table V is given a list and cost of the new equipment which must be purchased in order to utilize central station energy. Motors are provided to replace the present steam engines. All motors are alternating-current motors, and can be operated at any time, independently of the supply of direct current. In some cases it may be preferable to supply a direct-current motor for the hoist, in which event a larger motor generator is required. This increase may be in the form of a larger generator or of two generators driven by one large motor. One of the generators would be used for the direct-current supply for the mine and the other, with special control, for the hoist. If possible, the old hoist should be sold complete and an entire new electric hoist installed. In the present case, an alternating-current motor will be substituted for the steam engine at the hoist. A variable-speed alternating-current motor will be supplied for the fan. In many cases air compressors are used to supply air for punchers and pumps. It might be advisable to do away with air compressors entirely, and install electric cutters and motor-driven pumps, as the efficiency of the air system with its usual leaks is very low. However, in gaseous mines, it is sometimes considered dangerous to operate electrical apparatus, in which case a motor-driven compressor should be furnished.

TABLE VI. SALVAGE ON OLD EQUIPMENT

4 boilers with stacks		$400.00
2 feed pumps and water heater		90.00
2 150-hp. generator engines		600.00
2 100-kw. generators with belts and switchboard		600.00
Engine part of hoist		50.00
1 elevator engine		50.00
1 fan engine		75.00
1 screen engine		25.00
1 machine shop engine		25.00
1 conveyor and engine		30.00
2 steam pumps		50.00
Piping		50.00
Total salvage		$2,045.00
Total net cost		6,745.00
Interest at 5 per cent for 1 month	$28.00	
Depreciation at 5 per cent for 1 month	28.00	
Upkeep and repairs	15.00	
Total	$71.00	
Operating and fixed charges per kw.-hr. for new equipment		$0.0014

One thousand dollars has been allowed in Table V for the installation of the new apparatus. This should be ample to provide for foundations, alterations in building, wiring and mechanical application. The total cost is $8790.

In Table VI is shown the probable salvage that could be obtained for the old apparatus. These estimates should be kept rather low, since it is sometimes difficult to get good prices for old machinery. The total salvage amounts to $2045. The net cost of new equipment will, therefore, be $6745. The interest, depreciation, upkeep and repairs on the new equipment will amount to $71 per month. This is at the rate of $0.0014 per kilowatt-hour.

Specific Costs and Savings

In Table VII some specific costs and savings are given. The total cost of power per kilowatt-hour, saving per kilowatt-hour with purchased power, and the common cost in either case, as before mentioned, are first shown. If the common cost is added to the cost per kilowatt-hour with new equipment, we have $0.0066 as the total cost per kilowatt-hour with purchased power exclusive of the charge of the central station. If this value of $0.0066 is subtracted from the total cost per kilowatt-hour of $0.023, $0.0164 is obtained as the central-station charge which would make the total cost of power the same as at present. In other words, if the central-station rate were $0.0164 per kilowatt-hour, the total cost of power would be the same as at present. Any rate below $0.0164 will, therefore, represent a clear saving. At a rate of $0.0125 per kilowatt-hour, the saving would be $0.0039 per kilowatt-hour, or $2375 per year, which is a saving of 35.3 per cent. over all charges on the new investment. At this rate, the change would pay for itself in less than three years. At a rate of $0.01 per kilowatt-hour, the saving would be $3980, or 57.8 per cent. At this rate, the change would pay for itself in less than two years.

TABLE VII. COSTS

Total cost per kw.-hr. for power	$0.023
Saving per kw.-hr. if power is purchased	0.0178
Common cost, in either case, per kw.-hr.	$0.0052
Net operating and fixed charges per kw.-hr. for new equipment	0.0014
Total cost per kw.-hr. with purchased power, exclusive of central station charge	$0.0066
Charge per kw.-hr. by central station which would balance present cost	0.0164
Saving per year at central station rate of $0.0125 per kw.-hr.	$2375
Percentage profit on net investment of $6,745	35.3 per cent.
Saving per year at central station rate of $0.01 per kw.-hr.	$3890
Percentage profit on net investment	57.8 per cent.
Present cost per kw. capacity (5-minute peak) per year for fixed charges	$11.65
Present cost per kw.-hr. for operating expenses	0.0174
Total cost per kw.-hr. with purchased power at $0.0125 per kw.-hr.	0.0191
Total cost per kw.-hr. with purchased power at $0.01 per kw.-hr.	0.0166

A coal operator will readily understand that in his isolated plant he will have certain fixed charges which will be practically the same whether his plant operates or not. His power cost can be divided into fixed charges and operating costs. A central station supplying power

TABLE VIII. GENERAL DATA

Average working days per month	18	
Electrical kilowatt-hours per working day	800	
Electrical kilowatt-hours per non-working day	400	
Total steam and electric kilowatt-hours per working day	2,184	
Total steam and electric kilowatt-hours per non-working day	944	
Maximum electrical kilowatt demand, momentary peak	180	
Maximum electrical kilowatt demand, five-minute peak	150	
Maximum total steam and electric kilowatt demand, momentary peak	450	
Maximum total steam and electric kilowatt demand, five-minute peak	293	
Capacity of generators	200	
Total kilowatt-hours per month	50,640	
Kilowatt-hours per ton output, based on 19,800 tons per month		2.56
Present total cost of power per kilowatt-hour		0.0234
Present cost per ton output for power		0.0588
Cost per ton output for power with central station energy at $0.0125 per kilowatt-hour		0.0489
Cost per ton output for power with central station energy at $0.01 per kilowatt-hour		0.0425

for his mine will also have a certain part of its total cost as fixed charges. In many cases the fixed charges of the central station will be less than those incurred by the operator. The logical basis upon which to charge for central-station power would therefore be a certain fixed charge per kilowatt capacity of substation or kilowatt demand, plus a rate per kilowatt-hour which will be equivalent to the operating expense. In the present case, if the fixed charge were made $12 per year per kilowatt demand on a five-minute peak basis, the charge per kilowatt-hour would be $0.0067 to make the total cost equivalent to $0.0125 per kilowatt-hour. With the fixed charge system the total cost per kilowatt-hour decreases with the amount of power used. This is an incentive for the operator to extend the use of power as much as possible.

There are certain advantages that central-station power has over isolated plants that cannot be measured in dollars and cents, and in most cases, even when the fixed charge is the same as the operator would have in his own plant and the charge per kilowatt-hour is equal to his own operating expense, it would still be greatly to his advantage to purchase central-station power.

In Table VIII is given some general information in regard to the plant under consideration, showing the results of the tests and investigations, which should be made at a mine. The momentary and five-minute electrical peaks are obtained from the graphic records. These load curves are very interesting and show clearly the extremely fluctuating nature of the load, as well as the low average demand. The maximum momentary electrical load is often less than the continuous capacity of the generators. A modern commutating-pole generator of 100-kw. capacity would easily take care of the load where two 100-kw. old-type machines are used at present. A 150-kw. generator has been figured on to allow for the additional load of the pumps when changed to electric, and also to provide for future extensions. The information given in Table VIII will serve as a guide for the central station in determining the capacity of its lines, transformers, meters, switches, etc. The power required is 2.56 kilowatt-hours per ton mined. Since the cost per kilowatt-hour is $0.0234, the present total cost of power per ton mined will be $0.0588.

Conclusions

Summarizing the above information, the following reasons are given to prove the advisability of a mine's purchasing central-station energy rather than generating its own power.

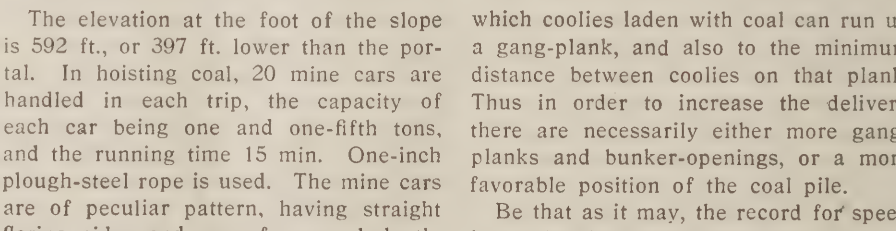
1. Lower cost of operation.
2. Worry and care of power plant removed. The legitimate business of a coal operator is to mine and ship coal, and he should not try to carry on another business of so different a nature, at the same time. The efficiency of his plant will be greatly increased if he can spend his entire time in looking after the mining and shipping of the coal.
3. Reliability, which means greater production.
4. Much less expense involved in shutting down mine.
5. Capital needed for new power plant can be used for new development.
6. Increased output and additional power can be obtained quickly with small increase in capital.
7. Increase of production on account of increase of efficiency, due to ample power at all times.
8. No change in speed of fan and pumps due to steam pressure falling occasionally.

About the only disadvantage is that additional capital is often required with which to purchase new apparatus, but when the large returns in the shape of decreased operating expenses are shown, this capital is not difficult to obtain.

Safety Device for Slope Car

By A. W. Evans*

The Rockwood slope of the Roan Iron Co., at Rockwood, Tenn., is located on the eastern escarpment of Waldens Ridge, at an elevation of 989 ft. above mean tide, and is driven through the conglomerate of the coal measures for a distance of 400 or 500 ft., until it intersects the Sewanee seam of coal, running thence, with the full dip of the seam, to its terminus, a distance of 4050 feet.



Safety Device for Man Car on Inclined Plane

The elevation at the foot of the slope is 592 ft., or 397 ft. lower than the portal. In hoisting coal, 20 mine cars are handled in each trip, the capacity of each car being one and one-fifth tons, and the running time 15 min. One-inch plough-steel rope is used. The mine cars are of peculiar pattern, having straight flaring sides and are of unusual depth. No one working in the mines is allowed to ride the loaded or empty trips, as the slope is tortuous in its ascent. Mr. William Richards, the superintendent, designed the car shown in Fig. 1, to convey the men to and from the working places.

In details of construction, the car is very simple, as will be noticed from the sketch. Double clevis hitchings are used. The feature deserving special mention is the device for catching the cars in case of the rope breaking or the hitchings giving away. This safety appliance is constructed of 1½-in. round iron, and bent as shown. When hoisting, the device is thrown back toward the rear of the car and drags the surface of the slope between the rails. Mr. Richards states that the catch is positive in its action. The bearings for the 1½-in. rod are located at the points where it passes through the sides of the car and are reinforced with 3x3-in. angle iron, which also serves to hold the sides in an upright position and to reinforce the car longitudinally.

*Brushy Mountain Coal Mines, Petros, Tenn.

The Record in Ship Coaling

There are those who assert that the average Asiatic laborer is not the most rapid and industrious in the world; but any naval officer who has had to go through with the disagreeable and dirty operation of ship-coaling, can confidently state that there are occasions and conditions, when there is little left to be desired in the way of rapidity of movement on the part of the coolie.

Up to a recent date the maximum rate of ship-coaling, was about 50 tons per hour. In November, 1905, however, the record was set at 92 and in February of 1906 even this record was surpassed by 8 tons per hour, bringing the average up to double that which was considered fair a few years ago.

It must be remarked in this connection that there is a limit to the space at which coolies laden with coal can run up a gang-plank, and also to the minimum distance between coolies on that plank. Thus in order to increase the delivery there are necessarily either more gang-planks and bunker-openings, or a more favorable position of the coal pile.

Be that as it may, the record for speed in coaling has again been raised by the British ship of war "Terrible," on which 1150 gross tons were brought and stowed away in 7½ hours—which figures out to about 150 tons per hour; in this case there were 8 bunker openings. During the liveliest time of this coaling the rate was 180 tons per hour.

Feeding Device for Tipple Screens

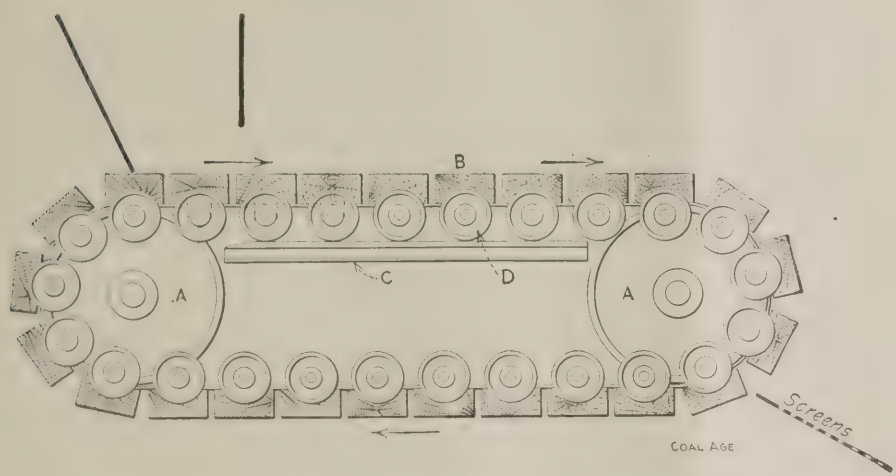
There are many coal-mining plants at which, on account of the lack of necessary tipple height, it is impracticable to have bar screens of sufficient length to properly screen the coal. In any case, one of the principal difficulties encountered in screening coal is the fact that where it is dumped directly from the mine cars onto the screens, the material passes down with a rush in large masses, carrying with it an undue proportion of small sizes and slack.

At the mine of the Carr Wood & Coal Co., near Lytle, Tex., the device shown in the accompanying sketch was devised by Mr. Carr to obviate this difficulty. The extra amount of power required to operate the attachment is so slight that it may be ignored. The mine cars dump in the usual manner, but the coal, instead of falling directly onto the screen bars, goes into a hopper, beneath the bottom of which passes a moving belt, constructed as hereafter described. This belt, being in continuous motion, conveys the coal from beneath the hopper, and delivers it upon the screens at uniform rate.

The apparatus has proved wholly satisfactory and is constructed as follows: The drums *A* may be made of any convenient material, and connected, preferably by sprocket and chain to the motive power. They should be approximately 3 ft. long, or extend at least 3 in. each side of the hopper bottom, and be placed not less than 4 or 5 ft. center to center, parallel and horizontal.

The belt consists of an endless strip of heavy canvas, brattice cloth or other available material, whose width equals the length of the rollers. To this cloth belt are attached, on the outside, wooden strips *B*, 2x4 in. by 3 ft. long, placed side by side to form a continuous circuit around both drums. The whole is made sufficiently tight to revolve when the drums are placed in motion.

Between the drums, on the upper path of the belt, should be placed a short section *C* of mine rail to provide a track for the small wheels *D*, placed on the ends of each strip *B* and thus prevent sagging of the belt from the weight of coal in the hopper. It is obvious that after passing over the forward roller *A* on the return run these wheels need no support until again reaching the upper portion of the circuit. The strips *B* may be placed loosely, side by side, forming a transversely rigid, but longitudinally flexible support for the belt.



TRAVELING BAND FEEDER FOR TIPPLE SCREENS

A simple slot and screw adjustment of the axle of one of the rollers *A*, is provided for loosening and tightening the belt. The whole apparatus may readily be constructed at any mining plant and with friable coals, or tipples having short or steep screens, will readily pay for itself.

Coal Land Development in Southern Utah

A coal-land and railroad transaction involving ten million dollars is being consummated by William G. Sharp, president of the United States Smelting, Refining & Mining Co. The coal properties are in Emery County, Utah, and the projected railroad is to be built from Provo to Mohrland, which is in the heart of the coal district.

That there is a plan under way to consolidate additional coal-land holdings in the Emery County zone and to create an extensive system of coal mines under one head is shown by pending negotiations for further purchases. Foremost among the interests named as the possible purchasers of the properties involved, are the United States Smelting, Refining & Mining Co. and the Davis coal combination of West Virginia. Mr. Sharp has been at work on the transaction since the first of February and has been assisted by Thomas Davis, who is at the head of the Davis coal interests.

The details of the transaction which have thus far come to light are as follows: Stock in the Castle Valley Coal Co. to the amount of $750,000 has been taken over by Mr. Sharp. The entire issue of Black Hawk coal mine stock, at a price said to be $600,000, has been transferred to him, and an option on Consolidated Fuel stock to the extent of $1,200,000 is arranged. In addition to these purchases, Mr. Sharp is assuming responsibility for outstanding bonds as follows: Castle Valley Coal Co., $1,200,000; Consolidated Fuel Co., $80,000. The estimated cost of the Utah Coal R.R., from Provo to Mohrland, is placed at $5,000,000, thus bringing the total amount involved up to $9,550,000. Stock is still outstanding as follows: Consolidated Fuel Co., $1,050,000; Castle Valley Coal Co., $800,000; making a total of $1,850,000.

The Utah Coal R.R.

The route of the Utah Coal R.R. will follow the main line of the Denver & Rio Grande south to Thistle. Then it will parallel the branch line running to Marysvale until it reaches Hilltop, here turning east and south to Mohrland. The maximum grade to Hilltop will be 1 per cent. and from Hilltop to Mohrland the grade will not exceed 2 per cent. The line will be 90 miles long. The outcroppings of the great coal measures are first encountered on the trip down from Hilltop, at an altitude of 8000 ft. The seams can be traced along their exposed outcroppings for a distance of 175 miles within the state of Utah. In fact, the same measures have been followed with comparatively slight breaks all the way down into Mexico. The beds along the line of the proposed railroad are anywhere from 18 to 32 ft. in thickness and as many as five are exposed in most places.

The new railroad will connect with the Castle Valley R.R. at Mohrland, making a continuous line through the coal region to Price. At present, the mines at Hiawatha and Mohrland and those along the route of the Castle Valley R.R. ship their coal to Price by this line and from there, it is carried to distributing points by the Denver & Rio Grande. Heretofore the great drawback complained of has been the inability of the Denver & Rio Grande to supply sufficient transportation facilities.

Thousands of acres of coal lands are available to the big interests that have entered this field. Aside from the properties that have been taken over and are being negotiated for by Mr. Sharp, large tracts are held by former United States Senator William H. Clark, P. J. Quealey, J. H. Mays and W. S. McCormick.

Current Coal Literature

The Best Thought Culled from Contemporary Technical Journals, Domestic and Foreign

Nitroglycerin

A bulletin of the Bureau of Mines, written by Walter O. Snelling and C. G. Storm, makes the following statements among others:

"Nitroglycerin begins to decompose at temperatures as low as 122 deg. or 140 deg. F. At a temperature of 158 deg. F., the commercial article evolves enough nitrous fumes to give a decided test with potassium-iodide-starch paper at the expiration of 15 to 30 min. Moreover, nitroglycerin even at very low temperatures tends to be somewhat volatile, and it is a well known fact that even at ordinary room temperatures it loses slowly in weight through volatilization. At somewhat higher temperatures, both its decomposition and evaporation increase.

Boiling Nitroglycerin

At a temperature of about 275 deg. F., the decomposition of nitroglycerin is so rapid that it causes the liquid to become of a strongly reddish color, owing to the absorption of the nitrous fumes resulting the decomposition of the liquid; and at a temperature of about 293 deg. F. the evolution of decomposition products is so rapid that at atmospheric pressure ebullition begins and the liquid "boils" strongly. This "boiling" is due in part to the evolution of decomposition products (mainly oxides of nitrogen and water vapor) and in part to the actual volatilization of nitrogen itself.

The decomposition is accompanied by the evolution of much heat, and as soon as ebullition has begun, enough heat is generated by the liquid to raise the temperature of the mass rapidly, unless some means is provided for conducting away the heat which is evolved. At temperatures between 293 and 419 deg. F., the ebullition of nitroglycerin becomes more and more violent; at higher temperatures the amount of heat produced by the decomposing liquid becomes proportionately greater, and at about 424.4 deg. F. nitroglycerin explodes.

Decomposition

When nitroglycerin is maintained at a temperature between 293 and 410 deg. F., its decomposition goes on rapidly, accompanied by much volatilization, and under these conditions nitroglycerin may be readily distilled. The distillate consists of nitroglycerin, nitric acid, water and other decomposition products. The residue which remains after heating nitroglycerin for some time under such conditions probably consists mainly of glycerin, with small amounts of dinitroglycerin, mononitroglycerin and other decomposition products. These substances are far less explosive than ordinary nitroglycerin, and accordingly by heating nitroglycerin slowly it can be caused to "boil" away, until the residue consists of products that are practically nonexplosive. In a number of experiments, nitroglycerin was thus heated, and a copious residue was obtained. By carefully raising the temperature, this residue could be made to char without explosion.

Departures from Standard

The temperature at which ebullition of nitroglycerin begins at normal atmospheric pressure was found to be 293 deg. F. This result is correct within four degrees, although different samples of nitroglycerin naturally have somewhat different ebullition points, depending upon acidity, length of time of storage, etc. The temperature at which explosion is brought about (424.4 deg. F.) should be accurate within about nine degrees, differences being due, not to the method of testing, but to the individual variations of different samples of nitroglycerin.

Rotting Mine Timbers

G. B. McDonald, in the "Iowa Engineer," makes the following comment on the action of fungi and bacteria in destroying mine timber. Decay in wood is an organic process caused by low forms of plant life, either bacteria or fungi. The bacteria are microscopic in size, but the fungi become conspicuous when the fruiting bodies appear on the surface of the wood. The fungi consist of small vegetable threads which penetrate the wood structure, and these are the real cause of decay rather than the fruiting bodies commonly known as punks, or brackets. Under proper conditions the spores produced by the fungi gain access to the wood structure, and decay soon begins.

The spores of the rot-producing fungi may gain access to the timber either before or after the timber has been felled; however, it is generally the case with mine timbers that the disease is contracted after the timber has been placed in the mine, due to its proximity to other decaying timbers. A rough wood furnishes excellent places for the lodgment of spores, and also good conditions for holding moisture, thus hastening the process of decay. Although timbers may have been sufficiently treated externally with some good preservative, the spores often gain entrance to the interior of the stick through season-checks or cracks which are not thoroughly protected by the preservative fluid.

It is frequently the case that a fungus is growing in the timber before the tree is felled. If the fungus is subsisting on live wood, and is not able to survive on dead tissue, the felling of the timber causes the death of the fungus and avoids further decay from that source. If the fungus is developing in the heartwood of the tree, which is practically dead tissue, the rot may continue to develop after the tree has been cut down and worked up into mine timbers.

Wood is composed of small cells, which are made of cellulose; around these cells is a substance known as lignin. Some species of fungi attack only the cellulose of the wood, others only the lignin around the cells, and still others disintegrate both lignin and cellulose, causing a complete breaking down of the wood structure. After the wood is first attacked by a fungus, discoloration takes place, and later the wood fibers are changed to such an extent as to make the wood soft, brittle and practically worthless for any purpose.

Any fungus must have for its proper development a supply of moisture, heat, air and food. Without any one of these the fungi cannot develop. In places where the timbers are constantly dry there is no danger of rot-producing fungi doing damage. The conditions which hasten the rotting of timber are those where the wood is constantly subjected to alternate wetting and drying. A good circulation of air is also an important factor in preserving timber in a mine, in that it tends to reduce the amount of moisture present. Shafts where ventilation is poor and where there is an abundance of moisture and heat are the most favorable for the development of fungus diseases. Although the loss of mine timbers can never be wholly prevented, yet their life can be very materially increased through proper methods of seasoning and preservative treatment.

For all classes of round timber, either posts, piles, or mine props, it is thoroughly understood that the removal of

the bark prevents decay to a certain extent. This is due to the fact that while the bark is on, the wood adjoining the inner bark is kept constantly moist, and the conditions are ideal for the development of fungus. The peeling is effective inasmuch as it hastens the seasoning process. The cost of peeling is an item which must necessarily be considered.

However, we are told by the Forest Service that it costs only from 20c. to 50c. per ton to peel mine timbers. It is no doubt true that many times this amount is saved by the increased length of life of the timbers. The simplest means of materially increasing the life of wood is by proper seasoning. It is well known that the amount of moisture in any piece of green timber depends upon the part of the tree from which the timber has been cut. The outer zone of a tree, or the sap-wood, contains a much greater amount of moisture than the heart-wood. On this account, and for the reason that the outer zone is more exposed to fungus spores, the sap-wood is more subject to decay than the heart-wood.

On the other hand, the sap-wood portion of a tree will season more rapidly than the heart-wood portion. By piling the timber in such manner as to permit a free circulation of air the seasoning process can be accomplished quite rapidly. The time required for the seasoning depends to a large extent on the climate. By kiln drying the moisture content of the timbers can be reduced to a smaller per cent. than by the mere process of seasoning; however, this will add a considerable item of expense.

It is well known that by reducing the moisture content the strength of the wood is materially increased, provided that an excessive amount of moisture is not driven off so that the wood structure is affected. A piece of timber well saturated with moisture is generally considered about one-half as strong as a properly seasoned stick.

Compensation

The first country to adopt a comprehensive system of accident compensation on a national scale was Germany in 1884; Austria followed in 1887, and since then practically all industrial foreign countries have adopted this plan, with greater or less modifications. Disregarding acts affecting only selected groups of workmen, the following list shows the order in which the various countries passed laws providing national systems of accident compensation: Germany, 1884; Austria, 1887; Norway, 1894; Finland, 1895; Great Britain, 1897; Denmark, 1898; Italy, 1898; France, 1898; Spain, 1900; New Zealand, 1900; South Australia, 1900; Netherlands, 1901; Greece, 1901; Sweden, 1901; Western Australia, 1902; Luxemburg, 1902; British Columbia, 1902; Russia, 1903; Belgium, 1903; Cape of Good Hope, 1905; Queensland, 1905; Hungary, 1907; Transvaal, 1907; Alberta, 1908; Quebec, 1909. The State of New York also passed a compensation law in 1910.

Canadian Fuel Production in 1911

By John McLeish*

The long continued strike which took place in the coal mines of southern Alberta and eastern British Columbia, was responsible for a considerable falling off in the coal production of Canada, in 1911.

The total production during the past year, comprising sales and shipments, colliery consumption and coal used in making coke is estimated at 11,291,553 short tons, valued at $26,378,477. This is a decrease of 1,617,599 tons or nearly 12.53 per cent. from the production of 1910, which was 12,909,152 tons, valued at $30,909,779.

There was an increase of 562,978 tons in the Nova Scotia production; that of New Brunswick remained practically stationary while an increase of about 23,097 tons is shown in Saskatchewan.

In Alberta, the decrease was about 1,396,412 tons or 48 per cent. and British Columbia also shows a falling off of 794,243 tons or nearly 24 per cent.

The production by provinces was approximately as follows:

Province	1910 Tons	1911 Tons
Nova Scotia	6,431,142	6,994,120
British Columbia ...	3,330,745	2,536,502
Alberta	2,894,469	1,498,057
Saskatchewan	181,156	204,253
New Brunswick ...	55,455	55,781
Yukon Territory ...	16,185	.2,840
Totals	12,909,152	11,291,553

The exports of coal in 1911 were 1,500,639 tons, valued at $4,357,074 as compared with exports of 2,377,049 tons in 1910, valued at $6,077,350, a decrease in exports of 876,410 tons.

Imports of coal during the year include bituminous 8,905,815 tons valued at $18,407,603; slack 1,632,500 tons, valued at $2,090,796 and anthracite 4,020,577, valued at $18,794,192, or a total of 14,588,892 tons valued at $39,292,591. The imports of coal in 1910 were, bituminous 5,966,466 tons; slack 1,365,281 tons and anthracite 3,266,235 tons, or a total of 9,872,924.

The total production of oven coke in 1911 was 847,402 tons valued at $2,340,674 as compared with the production of 902,715 tons valued at $3,462,872 in 1910. The total quantity of coal charged to ovens was 1,228,700 short tons.

By provinces the production was, Nova Scotia, 469,305 tons; Ontario 259,554 tons (made from imported coal); Alberta 36,216 tons and British Columbia 82,327 tons. All the coke produced was used in Canada with the exception of 9290 tons sold for export to the United States.

The quantity of coke imported during the calendar year was 751,389 tons, valued at $1,843,248 as compared with imports of 737,088 tons, valued at $1,908,725 in 1910.

*Chief of the Bureau of Statistics, Mines Department of Canada, Ottawa.

Note—Abstract from the Preliminary Report on the Mineral Production of Canada.

Promising Coal Fields in Arizona

Although Arizona has produced no coal on a commercial scale, it contains promising fields, which may be profitably exploited when transportation is afforded and when population and manufactures have reached a point which will provide a market for the output. The more important of these fields are the Black Mesa coal fields, in the Hopi and Navajo Indian reservations, which are included within Coconino, Navajo, and Apache counties, and the Deer Creek field, in the extreme eastern end of Pinal County.

The U. S. Geological Survey estimates that the coal land in the Black Mesa fields covers 5920 square miles, and that the fields contain 14,082,000,000 short tons, of which 8,000,000,000 tons are recoverable, the rest being under very heavy cover. The Deer Creek coal field includes an area of 30 square miles in the middle of the copper-producing region of Arizona, and, estimating that 24 in. of coal extends through the 30 square miles, the coal beds contain about 60,000,000 short tons.

In these fields there are two grades of coal—one a hard black coal, well adapted for transportation and for commercial uses and also possessing some coking quality; the other a soft, badly crushed coal, which carries a high percentage of ash and could probably not be marketed except locally. It is believed, however, that as this lower grade of coal is high in volatile matter it could be used for the manufacture of gas, to be piped to the places of consumption or used in the development of electrical power.

For the regenerative-flame arc lamp, the following advantages are claimed: 1. It is the only lamp combining the high efficiency of flame lamps with the long life of the inclosed lamp. 2. Long burning hours, 70 to 100 hours on one pair of carbons. 3. Low cost of carbons, 10 hr. for 2c. 4. High candle-power, 4000 candle-power maximum at 15 deg. from horizontal. 5. It is the most efficient method of lighting, replacing four to eight of the ordinary type of electric arc lamps. For colliery and shaft-head lighting a gas, fume, and waterproof case is provided.

Who's Who—in Coal Mining

Devoted to Brief Sketches of Prominent Men, Their Work and Ideas

The coal industry is full of champions. We have champion drillers, champion loaders, champion rescuers, champion transitmen, and some men are champion salary grabbers. In the matter of figuring out things Frank Haas, consulting engineer of the Consolidation Coal Co., Fairmont, W. Va., has the longest head and is captain of all the specialists in his line.

When it comes to exploding theories, Frank can slip up, ignite your pet idea, and get away before you know the durn thing is aflame. And, talk about "being from Missouri," well, Sir! the fellow who coined that expression meant Dayton, Ohio, and was looking straight at "F. H." when he uttered the words. Mr. Haas is the proverbial and original "show me," for every scheme that is presented for his approval not only has to be properly introduced, but has to eat, sleep and hold hands with him before anything resembling an "O.K." label is attached.

"Research" is his first name; "analytical" his middle appellation. With him a thought commences as an impression, strengthens to an idea, grows to a purpose, and culminates in action. He believes that the only way you can slowly master the whole is to dwell carefully on the details. Things invincible in their collective capacity, and in a state of union, gradually may be overcome when they are separated, and it is this habit of going to the bottom that has placed "F. H." at the top of his profession.

Born at Dayton, Ohio, in 1873, Frank Haas was educated at the common and high schools of his native town. Later he entered the Ohio State University, and in 1895 received the degree C. E. The following year was spent in post-graduate work, for which he received an E. M. degree.

In 1897, Mr. Haas was appointed chief chemist for the National Steel Co., Sharon, Penn. He remained at Sharon until 1899, when he was made superintendent of the Southern Coal & Transportation Co., Berryburg, W. Va. Leaving this latter position in 1900, he accepted a place as chemist and superintendent of Watts Furnaces, Virginia Iron, Coal & Coke Co., Middlesborough, Ky.

In 1901, "F. H." allied himself with the Fairmont Coal Co., Fairmont, W. Va., serving in the capacity of chief chemist. This was before the Fairmont people had perfected the great consolidation of companies that now exists and operates

FRANK HAAS

in four different states. The present big, fine building that houses the operating officials and engineering departments of the Consolidation Co., in Fairmont, had not been erected, and Mr. Haas' modest business abode was located in the basement of the old building. "Times do change," and he and his associates now are fixed so comfortably in their new headquarters, that a mere look at the elegance of their surroundings causes the average coal man to turn green with envy.

In 1905, Mr. Haas was made assistant general manager of the big corporation, then created and known as the Consolidation Coal Co. The new concern included not only the Fairmont mines, but also took in the biggest operations in the Georges Creek, Md., field, and mines located in the vicinity of Somerset, Penn. Recently the Consolidation company extended its sphere of activities into Kentucky, and within the next year, it is probable that this corporation will be producing more Kentucky coal than any other concern mining in that state.

In 1907, when there was a shift in the makeup of the official staff of the Consolidation company, Frank Haas was appointed consulting engineer, and since that time has actually been the head of the technical work of the company. A great part of his time during the past two years has been spent in the development of the new acreage in Kentucky.

The rapid rise of Mr. Haas to his present important position has been due almost entirely to his own earnest and efficient work. If, however, any one person had a hand in shaping his career and affording him needed opportunities, that person was the late Lee Malone, peer of mine managers, and one of the biggest, best men who ever engaged in mining coal. Mr. Malone started as a miner in the Fairmont field, and having only what education he gathered from the school of experience and hard knocks, he recognized in Mr. Haas the qualities and advantages he himself most lacked, and it is possible the "going" for Frank was made a bit smoother by Mr. Malone's early recognition of his unusual and valuable ability.

Frank Haas has not confined himself merely to the practical development and application of other people's ideas to his own work, but has made any number of original investigations along new lines. It is probable that the first work on coal calorimeters in this country was done by him, in association with the late Prof. N. W. Lord. In the matter of "High Humidity for Mine Ventilation," Mr. Haas is somewhat of a pioneer, and his ideas on this subject are based on actual practice at the mines under his control. He believes that the saturation of a mine atmosphere with steam is not for the purpose of furnishing the water for wetting the mine, but is done to prevent evaporation of water naturally in the workings. He says: "Theoretically, a place in a mine once thoroughly wetted and ventilated with a saturated atmosphere will remain wet indefinitely. This then is the condition which should be attained." He claims that in our shallow mines high humidity does not injure the men.

Concerning mine laws, "F. H." believes that all legislative measures should be short and concise and their enforcement rigid. Facts that are contained in volumes of matter are rarely discovered. He is also of the opinion that in our endeavors to supply the miner with plenty of air we have reached a point where the excess should be regulated. He believes over-ventilation is becoming a danger to the men.

During the past year, Mr. Haas has served as president of the West Virginia Coal Mining Institute, and the work of this body has increased in scope and efficiency under his régime.

Correspondence suitable for the columns of COAL AGE solicited and paid for. Name and address of correspondents must be given—not necessarily for publication.

Subscription price $3 per year in advance for 52 numbers to any post office in the United States or possessions, and Mexico. $4 to Canada. $5 to any other foreign country.

Subscribers in Great Britain, Europe and the British Colonies in the Eastern Hemisphere may send their subscriptions to the London office. Price 21 shillings.

Notice to discontinue should be written to the New York office in every instance.

Advertising copy should reach New York office by Thursday of week prior to date of issue.

Entered as second-class matter, October 14, 1911, at the post office at New York, New York, under the act of March 3, 1879.

Cable Address, "Coage," N. Y.

CIRCULATION STATEMENT

Of this issue of Coal Age, we will print 7600 copies. No copies will be sent free regularly. There will be no back numbers. The figures shown here each week represent live, net circulation.

This journal has a direct aim—a single purpose—which is to help advance the coal-mining industry. Its creed embodies the dissemination of knowledge and the free interchange of ideas among its readers, all of whom are invited to become regular contributors.

COAL AGE

Snap Judgment vs. Facts

The battle between truth and patriotism is still waging. Some value patriotism more than truth, some esteem truth more than patriotism, and then there are some who eschew both truth and patriotism and cover themselves with the *toga candida*, and seek office.

Under the government frank, bearing the eagle, laurel leaves and printing press of the Government Printing Office, circulates a little pamphlet in a paper cover entitled "A Federal Mining Commission, Address of John Randolph Haynes, M. D., Special Commissioner on Mine Accidents, State of California." It was read before the joint session of the American Economic Association and the Association for Labor Legislation at Washington, D. C., Dec. 30. 1911.

Dr. Haynes calls for our diatribes by stating that "some day we may come to regard fatalities which can be readily foreseen and so easily prevented as little better than murders." His remarks specifically refer to three-quarters of our fatalities, that being the number declared to be unnecessary. We by no means accept the statement that accidents can be reduced by prevision to one-fourth of their present frequency.

But even then, preventable, foreseeable accidents do not necessarily involve criminal carelessness and if they do, the charge will lie equally against miners and management. If the operator, who is unfortunate enough to lose a man by accidental death, is a murderer then by parity of reasoning, the man who is killed, as a result of lack of foresight is a dishonored suicide. To narrow our statement; most of the accidents are from roof falls. All such, if unnecessary, involve the contributory or sole negligence of the man killed.

Let it be remembered that the laws have been extremely stringent, compelling the operator to hire men to inspect the acts of the employee. It is severe and unjust to conclude that having gone to the full length of the legal requirements, and having moreover engaged rib bosses and timbermen for the workmen's further protection, the operator is still to receive the condemnation for all misadventures, both when the employee himself is alone blamable, and when the stigma, greater or smaller, cannot be rightly laid on anyone. Two deaths are said to have added to the glory of the Federal service, but if such deaths had occurred in the mining industry, there would have been some unpleasant insinuations at the inquiry. It would have been necessary to defend the training of the men, their apparatus and the quality of the oxygen supplied.

To prove his point, Mr. Haynes fairly wallows in statistics. He says: "From three to five thousand coal miners are annually killed outright in the United States." We cannot find that anyone of authority has ventured to give any such figures, and we think the estimates so far compiled are reasonably exact. True, authorities differ several hundred lives in a single year, but that is because some try to work with an exact calendar, and others mix the calendar year used by a state like Pennsylvania with the fiscal year of a state like Illinois.

The highest death rate, according to J. A. Holmes' computation, was 3127, and according to Frederick L. Hoffman, 2992. The latter statistician gives the average for the five years preceding 1910 as 2404. We do not know where J. R. Haynes got his data. Certainly not from high authority, though sometimes he follows such authority all too closely and flagrantly, by laying great stress on the death rate of 1907, when Monongah, Darr and Naomi swelled the number of dead inordinately.

He calmly compares the average rate of death in European countries with the black letter year in American annals. Every country has its years of evil import. England has the year of the "Hulton" disaster; France has that of Courrières, and it is not fair to balance years of misfortune in one country with the average years of another.

This special commissioner—special

forsooth, because no commissioner was really needed—has spent much time far over the mountains from his state. He could not learn much about mining at home because only about 0.003 per cent. of the coal mined in the United States would then be subject to his supervision. In fact, single mines without railroad facilities might easily be found mining 37 tons per day, which is as much coal as is extracted daily between San Diego and Crescent City.

He makes the statement that "of all American industries, mining is the most hazardous." This is perhaps true, in a manner, because nearly every person in that industry is exposed to its full hazard. About 70 per cent. of the mine workers labor underground, whereas in railroad work barely 20 per cent. of the workers are trainmen. Hence, a bare fifth of the men face the real hazards of railroading; the rest are more likely to die of nervous diseases, of diabetes, rheumatism and dyspepsia, than of an accident.

If, however, the coal workers as a body below and above ground are compared with the trainmen on the railroads of the United States, then the former have a distinct advantage, and even if underground coal workers alone are compared with trainmen, the latter have still a far larger death rate. In 1909 the death rate among trainmen was 4.87 per thousand, the year before it was 6.66, in 1907 it was 8 per thousand, and in the year preceding 8.07.

Mr. Haynes says that American conditions are safer than European. It may be so, but it will take a large amount of careful analysis to prove it. We are unwilling to accept it on his snap judgment. How much he may be relied on is shown by his statement that "up to the present time, Americans are not operating in the very deep levels of 4000 ft. or lower, not uncommon in Europe." A book published by no less a press than that of Cambridge, not more than a year ago, says: "In England we read that several collieries are 3000 ft. deep, and in Belgium two are nearly 4000 ft." How does this statement agree with that of Mr. Haynes?

It is well known that mines over 4000 ft. deep are regarded as doubtful problems for the future, and that the British Geological Survey has excluded deposits over 4000 ft. deep from its economic estimate of coal available. Many European mines are still less than 1000 ft. below the surface.

We know that this does not answer Mr. Haynes' comparison of home and alien mines, nor do we now desire to meet his statements in this editorial. But it may be permissible to say that experience in America has shown that where the greatest dangers are faced, the greatest death rate occurs. The anthracite regions and Colorado have distressingly high death rates, and yet these regions lead in preventive and corrective methods.

We doubt whether the eulogies of European countries are deserved. In 1909 in sixteen counties of Pennsylvania 1.45 lives were lost per thousand men employed. Looking over the list of "honor" we find counties recorded where safety is least considered, but where natural conditions assure the safety of the mines.

But Mr. Haynes has the Watteyne-Meissner-Desborough report to fall back on. The only report made by these three European experts to the United States makes none of the statements with which Mr. Haynes has credited them, and if it did, the case would not be proved. The casual observations of a stranger are interesting, naïve and oftentimes provoking, but they are rarely in all points just. The honorable commission did not, however, find in their report that American conditions were far better than in Belgium or France; they did not announce that an unbelievable state of carelessness, negligence and ignorance prevailed in the United States.

To show the dangers of snap judgments, we cite the fact that German mines have been badly infected by the hookworm. The German miner's span of life has been reduced thereby and his vitality impaired. In America the worm has not been a part of our disagreeable experience. Let it, therefore, be said that an unbelievable state of carelessness, negligence and ignorance prevails in the German Empire. We naturally hesitate to lay claims of this sort against Germany, or even Belgium, England, France or Hungary, though also infected.

Truth has the better of our ardent patriotism. Just as in those countries certain unfavorable hygienic conditions exist, not duplicated in American coal mines, so in our mines certain menaces to safety occur more markedly than in England. As a matter of fact, coal dust conditions in America are as different from those in Europe, as the mountain mine conditions in Colorado are different from those in the lower hill country mines of Pennsylvania. The roof risk is also a problem not altogether personal.

This active commissioner of labor has discovered that in 1869 there was a disaster at Avondale in Luzerne Co., Penn. "Many a miner since then has lost his life from the burning of wooden shaft structures erected since the Avondale disaster." We only recall the burning of the shaft timbers in one working mine of America since that time, and the fire did not start in the shaft but in the mine. We recall, however, that last year the Threslington colliery buildings, West Cornforth, England, burnt down and "lumps of burning timber" fell down both shafts, the "pithead being a mass of flames."

To return to our pamphlet, we are told by Mr. Haynes that the Briceville, Tenn., accident is one of many cases where a "second opening to the mine would have saved hundreds of lives." We cannot see how any more men could have been saved than were in the mine, nor even how more men could have been saved than were actually killed. We cannot understand how the commissioner can conclude there was but one opening when there were at least three. So here again the argument lags.

Mr. Haynes desires the formation of a Federal Commission of five members, three of whom are scientific men, selected for their special eminence in the subject of coal mining. Let it be duly noted that John Randolph Haynes cannot meet such onerous requirements. The voters should mark him well, and if his name is proposed, see that he be not appointed; for, to judge by his remarks, he could not pass a mine foreman's examination.

And lest some should think we are too severe, we quote some of the further gems of thought from this work: "In Europe a situation where a mine foreman could not read would not be understood. In America almost anybody is considered good enough to be a mine foreman." "The coal miner is prone by his occupation to tuberculosis and other diseases." And here, that we may not weary the Court, we rest our case.

Examination Questions

Selected from State Examinations, or Suggested by Correspondents

British Columbia Examinations for First Class Certificates — Ventilation

Ques.—Describe one system of ventilation and general management you would adopt in a gaseous mine in order to keep the mine in a safe condition, both as to explosion and other causes.

Ans.—To avoid as far as possible the ignition of gas by the drivers' lamps, the main haulage road should be made the intake air course for the mine. To do this and to avoid the necessity of doors on the main haulage roads, the mine must be ventilated on the exhaust system. The general plan of the mine and the arrangement of the main entries will depend largely on the size of the proposition. The main roads should be driven on the double- or the triple-entry system, preferably the latter. In the triple-entry system the middle entry is the intake and haulage road, the two flank entries should be the return air courses for their respective sides of the mine. The mine should be equipped with a good type of centrifugal fan so arranged that the air current in the mine can be reversed in case of need. The fan should be set back a short distance from the top of the air shaft and explosion doors provided to prevent, as far as possible, the destruction of the fan in case of an explosion occurring in the mine. All doors and other equipments at the shaft bottom and elsewhere in the mine should be constructed of incombustible material. Double doors should be used at all main points in the air courses, and emergency doors should be provided wherever the short circuiting of the air, in case of an explosion destroying the doors, would cut off the escape of the men. As far as practicable, these emergency doors should be so arranged as to close automatically in the event of an explosion. A strict discipline should be maintained throughout the mine in regard to the use of lamps, oils, powder and other material.

Ques.—Describe the principle on which a mine fan operates and does its work. How should the outlet to an exhaust fan be arranged so as to allow the air from the mine to be discharged freely? The area of the discharge opening of a fan is 5 ft. by 5 ft. and the quantity of air passing through the fan 50,000 cu.ft. per min.; what theoretical effect will be produced by building on this opening a chimney that will gradually expand until the dimension of the discharge will be 10 ft. by 10 ft.?

Ans.—With respect to their principle of operation there are two types of mine fans: (1) The disk fan, which acts by propelling the air by means of the rotation of its inclined blades. The principle is the reverse of that of the propeller of a ship. The rotation of the propeller drives the ship forward, owing to the resistance of the water. The rotation of the disk fan drives the air forward, the fan remaining in place.

(2) The centrifugal fan acts on a different principle from that just described. The rotation of this fan develops a certain centrifugal force determined by the weight of air revolved in the fan and the velocity of its rotation. The centrifugal force developed is exerted radially outward, causing the air to flow from the center toward the circumference of the fan. The air enters the center of the fan and is discharged at its circumference.

The action of the fan creates a difference of pressure between the intake and discharge openings. The amount of this pressure, however, is determined by the resistance of the mine. Cut out or reduce the mine resistance and the pressure falls. The greater the pressure established by the mine or the greater the mine resistance the less the quantity of air circulated by the same power.

(b) The area of the discharge opening, 5x5 ft., is 25 sq.ft., which for a volume of air of 50,000 cu.ft. per min. gives a velocity of $50,000 \div 25 = 2000$ ft. per min. The theoretical effect produced by enlarging the area of discharge by building an expanding chimney, so that the area at the point of discharge will be $10 \times 10 = 100$ sq.ft., will be to reduce the velocity of discharge in the same ratio in which the area is increased, making it $\frac{1}{4}$ of the original velocity, or in this case 500 ft. per min. The head due to the velocity of discharge varies as the square of the velocity. In this case, therefore, the theoretical effect is to reduce the head due to the velocity of discharge, or to reduce the loss of head, in the ratio $(\frac{1}{4})^2 = \frac{1}{16}$. In other words, the loss of head due to the velocity of discharge is $\frac{1}{16}$ of what it was before the chimney was built.

Ques.—How will a current of 100,000 cu.ft. per min., passing in the main airway of a mine, divide between the following three splits?

Split A, 6 ft. x 6 ft., 2000 ft. long.
Split B, 6 ft. x 6 ft., 4000 ft. long
Split C, 6 ft. x 6 ft., 6000 ft. long.

Find the quantity of air that will pass in each split, supposing the pressure on all the splits to be the same.*

Ans.—Since all the splits have the same cross-section; namely, 6 ft. x 6 ft., the area and the perimeter, in each split, are the same; and, for the same pressure per sq.ft. at the mouth of each split, the quantity of air in circulation is inversely proportional to the square root of the length of the split. It is necessary, first, to find the value of the split potential, in each case, which becomes here, the area and perimeter being constant $\frac{1}{\sqrt{l}}$. In this method, the work is much simplified by reducing the lengths, 2000, 4000, 6000 to the lower related values 2, 4, 6, and substituting these for l in the above expression; thus,

Split A,

$$\frac{1}{\sqrt{l}} = \frac{1}{\sqrt{2}} = 0.707$$

Split B,

$$\frac{1}{\sqrt{l}} = \frac{1}{\sqrt{4}} = 0.500$$

Split C,

$$\frac{1}{\sqrt{l}} = \frac{1}{\sqrt{6}} = 0.408$$

Total 1.615

Since the quantity of air passing in each split is proportional to the split potential, the several quantities of air passing are found for each split; thus,

Split A,

$$\frac{0.707}{1.615} \times 100,000 = 43,777 \textit{ cu.ft. per min.}$$

Split B,

$$\frac{0.500}{1.615} \times 100,000 = 30,960 \textit{ cu.ft. per min.}$$

Split C,

$$\frac{0.408}{1.615} \times 100,000 = 25,263 \textit{ cu.ft. per min.}$$

Total 100,000

*Note—The reading in the above question has been slightly changed from the original so as to make the statement of the question harmonious. The original question states, "the current (100,000 cu.ft.) passes through an airway 6x5 ft., 10,000 ft. long, which is divided into three splits," giving the splits as above. This statement is at variance with itself. Since the areas of the airways in all the splits is 6x6 ft. and the total length of the splits is 12,000 ft. instead of 10,000 ft.—Editor.

Discussion by Readers

Comment, Criticism and Debate upon Previous Articles, and Letters from Practical Men

Booster and Tandem Fans

Letter No. 1—Concerning the discussion of the use of a "booster" fan to assist the regular fan, in the ventilation of a mine; and the use of "tandem" fans, or two fans operating on the same air current, the one blowing and the other exhausting, I am glad to offer the following remarks:

The so called "booster" fan will, undoubtedly, often permit the working of places where the air would otherwise be insufficient for the requirements, owing to leaky doors, stoppings, etc. We know that all mine ventilation depends on the principle that the moving force or the force creating ventilation is the difference between two pressures namely, the pressures on the air at the intake and return openings, respectively. With the same pressure at both ends of an airway, no current will be created.

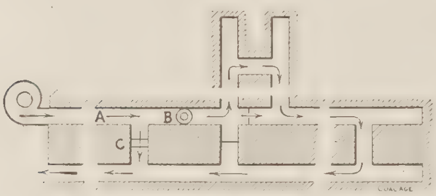

Fig. 1. Showing Location of "Booster" To Overcome Effect of Leaky Stopping etc.

It is this condition that gives rise to bad-air periods, in mines dependent on natural ventilation alone. This condition occurs frequently in the spring and fall seasons, when the outside and inside temperatures are alike. The same condition may also occur in the inner sections of a mine, owing to the leakage of air through poorly constructed stoppings and doors. When this is the case, there is practically no circulation of air in that section of the mine, which is thus cut off from the main air current.

To overcome this difficulty, it is common to install a "booster" fan within the mine, at the mouth of the affected section. This booster fan at once, by its action, creates a difference of pressure, increasing the pressure on the intake of the section over that on the return. The installation of this "booster" does not materially affect the total quantity of air entering or leaving the mine; but overcomes the tendency of the air to pass through the leaky stoppings and doors by creating a depression in that portion of the airway and throwing the air forward into the inner section of the mine.

I have indicated, in a brief way, in the accompanying sketch (Fig. 1), the location of the "booster" fan *B*, with respect to the pitch headings adjacent where the circulation of air was deficient. At the point marked *A*, within the mine, the effective pressure of the principal fan is *nil*. The last bit of air is leaking through the brattice marked *C*. The "booster" fan installed at *B* is very effective in forcing air to the face of the pitch headings. It is under these conditions that the so called "booster" will assist, so to speak, the principal fan and permit men to work in places where they could not work previously, owing to the foul air.

The advocate of the "booster" fan was, therefore, right when he said "It would permit him to work his men in places where he could not work them without this fan." The other superintendent was, also, perfectly justified in saying that the second fan erected over the upcast shaft to assist the blowing fan at the downcast shaft would not "draw." Naturally, the second fan acted as an impediment or obstruction to the air current and decreased the efficiency of the first fan, since the air current created by the first fan must pass through the second, which offers a certain resistance to its passage. This resistance of the second fan to the passage of air is due to the friction of the air against its surfaces and the deflection it meets in passing through the fan. Two fans will always offer twice the resistance of one fan to the same air current.

The Action of Twin Fans

In Figs. 2, I have shown two arrangements employing two fans in each. In the first arrangement, Fig. 2, (*a*), the fans are arranged in tandem, the one blowing and the other exhausting. The blowing fan is placed at the intake opening of the mine and the exhaust fan at the discharge opening. In this case, all of the air created by the first fan must pass through the second. In the second arrangement (*b*), both fans are placed either at the intake or the discharge opening of the mine. The fans work side by side, each taking its own portion of air. In this case, it is often supposed that the two fans will produce twice the quantity of air that would be produced in the same airway by one fan working alone; but this is not the case.

The operation of the two fans will necessitate an increase of power and produce also an increase in the circulation. If no change is made in the course of the air through the mine, any desired increase of quantity will require an increase of power in proportion to the cube of the ratio in which it is required to increase the quantity. Thus, to double the quantity will require eight times the power. Two fans operated side by side would produce, assuming the power on the air was doubled, an increase of quantity in proportion to the cube root of 2. Thus, $\sqrt[3]{2} = 1.26$. If each of these fans, working alone, would produce a current of 20,000 cu.ft. per min. in this airway; when working together, they would produce $20{,}000 \times 1.26 = 25{,}200$ cu.ft. per min. It is important to remember, however, that since one-half of this volume of air is passing through each fan, the

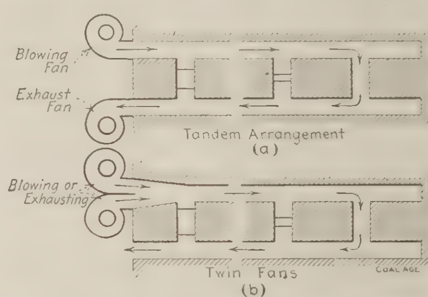

Fig. 2. Showing Right (a) and Wrong (b) Ways of Installing Two Fans On a Single Current

work lost in each fan will be proportionately less; and, as a result, the two fans will produce a slightly larger quantity of air than that above named. In other words, the circulation with two fans running side by side will have a higher efficiency than can be realized in the operation of a single fan capable of producing the same quantity of air.

R. Z. Virgin.

Johnstown, Penn.

Letter No. 2—Referring to the question in regard to the practicability of installing a "booster" fan to assist the main fan; contained in your Foreword of May 25, I wish to say that "booster" fans are of advantage in mines where the air travel is very long, where air courses are of insufficient size to keep down the water gage, or where the coal pitches. I can think of no disadvantage due to the use of "booster" fans under any circumstances. In all instances they will prevent loss of air by leakage due to great pressure where only one fan is

used. The principal expense is the cost of the fan itself and the power for running it, which generally is electricity, which means the carrying of power for a long distance with the cost of copper and transmission losses.

CARL SCHOLZ.
Vice-Pres. and Gen. Mgr.
Consolidated Indiana Coal Co.,
Chicago, Ill.

Letter No. 3—"Is a booster or tandem fan practical, and will it increase the quantity of air, when both are operating on the same air current?" I say, yes; it is practical and will increase the volume of air in proporion to the size and speed of the second fan.

The Consolidated Indiana Coal Co., at its No. 25 mine, located in Sullivan County, Ind., installed a 6-ft. booster, electric-driven fan, in the intake airway, on one side of the mine, 1000 ft. from the foot of the downcast shaft. At the top of this shaft there is a 12-ft. steam-driven Crawford-McCrimmon fan, running about 115 r.p.m. With the latter fan running alone, the ventilation on this side of the mine was poor and not sufficient for the number of employees in that section. Something had to be done and it was decided to install the booster.

This booster is a disk fan, similar in construction to the Stine disk fan; and is geared to a mining-machine motor. The fan is running at 350 r.p.m., and since it has been in operation the quantity of air in that air course is increased nearly threefold, as shown by measuring the air before and after the installation was made. These facts can be verified by anyone who desires to come and measure the air when the fan is not running and, again, when it is running. The booster only runs during working hours, and when first installed was run at 550 r.p.m. This speed, however, had to be reduced as the booster took too much current to drive it, and at that speed made air enough to blow open the mine doors on the inside, which were hung so as to open both ways. If we give mine ventilation any study, and reason for a minute we will see the practicability of a booster fan when properly arranged.

In passing air through the air courses of any mine, friction must be overcome; and as the air courses increase in length or contract in area the quantity of air decreases unless the speed of the fan can be raised so as to keep pace with the increase of friction, which is not always practicable. But, when the fan has reached its limit, if we place another fan on the same air current, either midway in the air course or at the outlet, it will have the same effect as if we cut the length of the airway in two. Let us not make the mistake, however, that some have made, by placing two fans on the top of the same air shaft, and expect results, for the fans so arranged, will often work against each other, and the ventilation will become worse than before the erection of the second fan.

Shelburn, Ind. R. J. PICKETT.

Letter No. 4—As to whether it is possible to run a "booster" fan to assist another fan to ventilate a mine, will say: If a blowing fan is forcing the air into a mine, but, on account of leaky doors and stoppings, a part of the inner workings or a certain section of the mine is not getting sufficient air, the intake entry of this section being, as we say, "dead," there is no doubt but that a "booster" can be installed at this point, which would take off enough air from the main air current and circulate the same through this section and back to the main current. The "booster" fan would thus assist the main fan to properly ventilate the mine, providing, however, the main fan is producing a sufficient volume of air for the entire mine.

I am inclined, also, to believe that when the main fan, working on a continuous current, there being no air splits, does not produce sufficient air for the mine, a "booster" fan, installed near the head of the mine within the workings, would greatly assist the circulation of the air. This condition will often occur in the development of a mine, the mine resistance becoming too great for the power of the fan, owing to the increase of friction and pressure. When the main fan, on this account, fails to produce the necessary velocity in the workings, it seems to me that a "booster" at the head of the mine, if of sufficient capacity, will pick up the air delivered to it by the main fan and drive it out of the mine.

But, as for running two fans tandem, that is to say, one at the top of the downcast shaft, forcing the air into the mine, and the other at the top of the upcast shaft, exhausting the air from the mine, I do not believe this plan would improve the ventilation of the mine, for the following reasons:

(1) If there were leaky stoppings, cutting the air off from some section of the mine, the exhaust fan would only pull the air through the leaky stoppings into the return current, and still leave the unventilated section of the mine in the same condition as before.

(2) Again, in case all of the stoppings are in good condition, it does not seem to me that tandem fans would even then increase the volume of air in circulation, because, the forcing fan can only produce a given volume of air, and the exhaust fan cannot get any more air than the first fan delivers. In this case, therefore, it seems to me that both fans would be working on the same volume of air that one of these fans could produce alone. I do not claim to be familiar with this subject wholly, but these are my ideas, and I shall watch this discussion, by others, with much pleasure.

Gatliff, Ky. J. C. BABB.

Letter No. 5—Replying to the Foreword, COAL AGE, May 25, in which you ask for a full and free discussion as to the possibility of operating a "booster" fan to assist the principal fan in ventilating a mine, I beg to advise that, in my opinion, it is possible. This opinion is supported by the fact that I have done this very thing. I do not, however, believe it to be good mining practice. Lack of money to purchase a more efficient fan was the chief reason, in this case, for the installation of the "booster."

I consider the "booster" a "make shift," its use in most cases being forced on the operator by lack of money or time to procure a better facility.

It is unnecessary to say that there should be no leaky stoppings; or the air courses should not be cheked by falls and other obstructions in the airways. It is, however, easier to say this than to do it; or to remedy the trouble from leaky stoppings. This is especially true in a mine giving off little or no gas.

When a coal company is managed by a man who has had no experience in mining but whose experience lies in dividend getting in other lines of business, the ventilation of the mine is apt to be regarded as an unnecessary expense. It takes a strong showing to convince such a one of the benefits to be derived from the expenditure of a sum sufficient to install a ventilating apparatus having the proper efficiency. Hence the installation of the "booster" or some other make shift.

I know of other cases than my own where "boosters" have been installed; and there seems to be no doubt as to the possibility of getting some results thereby; but there is some doubt as to the practicability of adopting this plan. Unless forced to do so by circumstances as first related, I would not install a "booster."

G. M. SHOEMAKER, MANAGER,
THE VIRGINIA-LEE COMPANY, INC.
Pennington Gap, Va.

[Further discussion relative to the use of "Booster" fans will be printed next week. All readers are invited to contribute.—EDITOR.]

Young Mine Foremen

On reading the article of Sim and W. H. Reynolds, in the issue of May 25, on "The Dangers of the Pittsburgh Coal," I was most forcibly struck by the keen language which so ably delineated the old man's attitude at the Pittsburgh demonstration. Shakespeare's Shylock is no more in evidence in my mind than is Reynolds' old-time mine boss.

In the presentation they have given us, we see the embodiment of ignorance,

doubt and denial. The old man's mien, his language, the envelope and the dust he holds in his shaking hand, all bring him vividly before us. We can watch him as he notes that the scientific know-alls failed to blow the mine up. Finally the deed is done, and the workings of the old man's brain are not depicted by Brother Reynolds, but he says enough when he records the fact, "that the old mine boss changed his opinion."

We are all heartily glad to hear that he did so, and it is one of the desired ends of such meetings that such men should be convinced. If fossils like the one described can be brought to light by such Sinaitic thunderings, then there is hope that the masses may fully realize the tremendous fact that dust will explode.

But this was not the passage in the article which took away my breath. I do not believe that the writer intended a "solar plexus" blow to us old men, but such a construction could well be put on the passage which follows and loose inferences could be drawn from what is said. Some might conclude that most old men belong to the same school, what old school is not designated, and by parity of reasoning it might be concluded that younger men belong to quite a different school. To give the quotation: "As he ambled about, he convinced us that there still existed, if not among the younger men, at least among many of the old school of mine officials, who are equally charged by the state with the care of many human lives, such a narrowness of mind and viewpoint, as is apt at some time or another to be the cause of a disaster." Now, I must confess I cannot grasp the distinction between the schools, as far as age limits are concerned, nor as far as my observations extend. Of course, I take mining life to be a great school. In fact all life itself is only a school, and a man with an open, progressive mind, watching events, learning facts, and keeping in touch with the spirit of the age is always young to me. The spirit never grows old. And I have seen, and so have you, and so has Brother Reynolds, sulky, dull, pig-headed and very dogmatic young men and very progressive so called old men. In fact, youth is generally a period when "they know it all." There comes a time when one does not know too much, and then again —well—we mumble out something like this: "There are more things in heaven and earth than are dreamt of in our philosophy."

In closing I would say, keep the dust and gas out of your mine, keep your mine damp and your air moist and use the best tested explosives, never failing to keep up with this age of ideas and then human suffering and loss of life, if not eliminated, will be brought down to a figure worthy of our united efforts.

Eccles, W. Va. George Scott.

A Cave-in Proposition

I have read with interest Mr. Sutton's proposition for dealing with a cave, published in Coal Age, May 18, p. 1050. There is no doubt that Mr. Sutton's method would give good results, under certain conditions I would suggest, however, modifying his method whenever the rooms are connected by cut-throughs. The chief objection to Mr. Sutton's method is the number of curtains required on the entry or haulage road. As the life of curtains is necessarily short when all the coal from a heading must be hauled through them, their use on a haulage road should be avoided, as far as possible.

I submit herewith a diagram (Fig. 1) of the plan I would adopt in the present case. This figure shows the brattices carried up from the last cut-through to

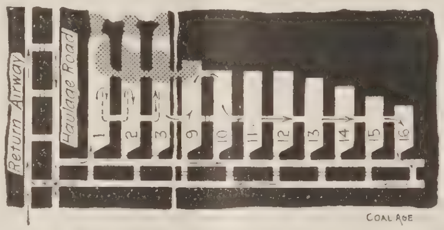

Fig. 1. Showing Arrangement of Brattices To Ventilate Caved Rooms

the edge of the fall at the face of each room. A curtain is then placed on the heading between rooms 1 and 2, and another curtain on the heading between rooms 9 and 10; a curtain is also hung in the mouth of each intervening room. As shown in the sketch, the brattice is attached to the outby rib of the cut-through, in each case; and, except in room 1, they are erected on the straight-rib side of the room, so that the fresh air travels behind the brattice. Care should be taken that the area behind the brattice is sufficient to conduct an ample volume of air without increasing too much the velocity of the current and the mine resistance. Since the fall has not closed the second cut-through between rooms 9 and 10, a stopping is shown placed in the first cut-through between these rooms, to deflect the air to the face of the room.

Johnstown, Penn. Benj. Hartill.

Haynes and Briceville

In regard to the statement of John Randolph Haynes, in his address to the American Economic Association, Dec. 30, 1911, we beg to advise that we have three openings at our Cross Mountain mines, all of which are or can be used as traveling ways. The mine law of the state of Tennessee requires two openings not closer than 150 ft. apart, and we more than complied with that requirement. I might also add that our air shaft which is located 3100 ft. from the mouth of our mine can be used as an outlet, and had there been any men alive in our mines in that vicinity, they could have been rescued.

I may also state that within 30 minutes after the explosion, we had men at the bottom of the air shaft, these men having traveled 3000 ft. along the main entry. When the men reached the bottom of the shaft, we had ropes let down from above by which supplies were furnished so that we could commence to build brattices where needed.

I might say in connection with the comments made by John Randolph Haynes, that we have 2500 ft. of cover over our mine and other companies have leases on either side of our workings. Consequently openings could not be arranged close up to the working places of the mine. However, the following exits were available for travel: The main opening, the haulage road and a manhole. If necessary we could have removed men by the air shaft of which mention has been made above.

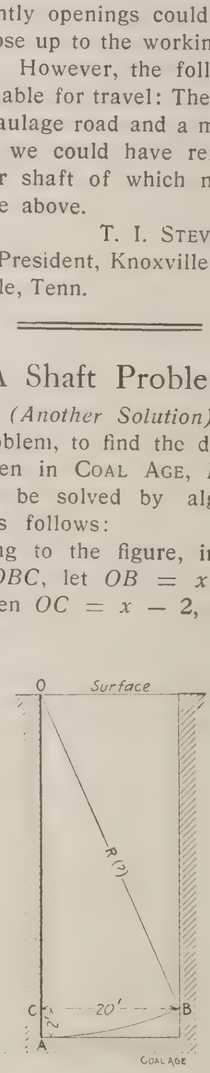
T. I. Stevenson,
President, Knoxville Iron Co.
Knoxville, Tenn.

A Shaft Problem

(Another Solution)

The problem, to find the depth of the shaft, given in Coal Age, May 25, p. 1086, can be solved by algebra very simply, as follows:

Referring to the figure, in the right triangle OBC, let $OB = x$ (depth of shaft), then $OC = x - 2$, and $BC = 20$ ft.



Showing Cross-section of Shaft

But, the triangle OBC being right angled at C,

$$(OB)^2 = (OC)^2 + (BC)^2$$

Or, substituting the values given above,

$$x^2 = (x - 2)^2 + 20^2$$
$$x^2 = x^2 - 4x + 4 + 400$$

Transposing and reducing,

$$4x = 404$$
$$x = 101 \text{ ft.}$$

Consulting Engineer.
Honesdale, Penn.

Sociological Department

For the Betterment of Living Conditions in Mining Communities

Law Breaking and Mine Discipline

By Sim Reynolds* and W. H. Reynolds

To many men, officials as well as miners, certain provisions of our present laws seem unnecessarily strenuous and uncalled for. These men fail to realize the positive necessity for laws applying equally to all men and all mines. They cannot or will not make distinctions themselves, yet they would have the mining code do so. Witness, for instance, the stir some time ago, created by the attempted application on the part of the Pennsylvania Department of Mines for a wise and necessary act regulating shotfiring and the use of tested powders. The attempt to carry this act into execution for the benefit of a certain class of miners met with a stubborn resistance of the very men, one would naturally have expected to welcome it. The fact that the department's desire to safeguard the lives of these thousands of men seemed likely to take a few pennies from the pay of the men to be benefited, caused a strike which need not be dilated upon, since every reader of this journal is doubtless familiar with the matter. When the men themselves prove unwilling to pay a few cents a day to remove only one of several elements of extreme danger, should we wonder if we find employers indifferent?

The miners of the Pittsburg district were self-blinded to the fact that to be of any service a regulation of that sort must of necessity cover the entire field wherever need of such legislative action existed, that if A's mine was fortunately such that wholly or in part it could operate safely without this safeguard, yet to make a distinction in favor of A's men would obviously call for the same favor elsewhere, and with real or imaginary changing of cause and effect between one mine and another, the whole structure built for the safety of the region would sooner or later topple on the heads of those who made it.

The Laws Cannot Be Framed for Every Individual Circumstance

It seems not to occur to some men that there are few laws—be they framed for the betterment of social, business or industrial conditions—which do not inevitably work hardship at some point or other. Even the imprisonment of a criminal makes others beside himself suffer. These hardships in the enforcement of laws will always exist, so long as no two mines have characteristics exactly alike. Some little that is bad will have to be endured for the greater good which is conferred

The best that can be done for imperfect human beings is to endeavor to give the greatest possible measure of good to the greatest possible number. Yet, failing to fully realize this philosophy, men singly and collectively set about breaking these laws by fitting them to their individual needs and circumstances. And it is because of this fact that we need more and still more education along our own lines. It is this attitude which calls into being stringent laws, and gives us an inflexible determination to enforce discipline and carry out what laws we have.

Everybody Does His Part to Make the Mines Unsafe

Nor is the miner alone in this respect. At this moment there come flooding upon our memories a full score of cases which take in every one connected with the industry. The careless trapper boy leaves a door but partly shut, trusting or pretending to trust to the backward kick he gives at it as he swings onto the tail end of an ingoing or outbound trip. Perhaps he gets back an hour later to shut it if someone hasn't happened to go through ahead of him. Thus the ventilation of a gaseous section is left to the operation of an uncertain chance.

There is the manager, who, at some time or other, breaks every section of the code, as each in turn stands between him and a constant and large output, and the corps of engineers which enters an abandoned part of a gaseous mine which has not been previously examined for gas. The imputation of carelessness covers them all, and if death happen to pass over the first offense, they will be found doing the same thing over again just as did an offender who recently came under our notice.

Experience Does Not Teach

This latter instance resulted in our bringing up for punishment an old man, who ought to have known better than to be caught with smoking materials and matches on his person in a mine where such luxuries were strictly forbidden during working hours. The same man had, but a short time before, been removed from a mine which had like characteristics to the one he was entering, and which had blown up and killed every living being in it except himself. When he was asked regarding his carelessness, he replied simply that he "didn't think there was any danger." Another miner who worked beside us in a mine in northwestern Pennsylvania thought the same regarding his powder keg. He would persist in opening the steel canister by some method other than the sane way, which consists in removing the cap, but one day the steel pick point went in among the black grains with a few friction-engendered sparks, and Paddy left his wife and "childer" to hustle thereafter for themselves. Still another miner we knew, when removing old lamp wicks to put in new ones, had fostered the habit of placing them on the edge of his powder keg, instead of on a flat rock, many of which lay near by. In the end this man also left his family to the tender mercies of a far from tender world, because a lamp wick, obviously being slippery with grease, slipped into the "kagg."

Discipline Is for the Other Fellow

But, "lest we forget," we must ever keep in mind the fact that these men of lowly station, who "tak a whiff" when the bosses aren't near, or, like those mentioned, deliberately disobey the law with regard to the handling of powder, are not one whit worse, nor more deserving of severe punishment than the foreman or manager of a dusty mine who persists in ignoring the dangers of dust alone, and who in a spirit of narrowmindedness professes to hold nothing but contempt for the men, governmental or local, who would have them acknowledge that the innocent-looking coal dust is an element of great danger.

*Pittsburg-Buffalo Coal Co., Marianna, Penn.

Safety Warnings

On the statements given to the miners at the Pine Hill Colliery, near Minersville, Schulykill County, Penn., safety warnings have been printed. These lay stress on the fact that men are frequently killed, because the prudent men are afraid to "butt in" and warn the imprudent of the dangers to which they are exposing themselves. The mine foreman is not the only man who should have safety in his mind. If everybody warned his neighbor of the imprudence of tempting death, there would be less loss of life. The practice of the Pine Hill authorities is commended as likely to do much good.

Coal and Coke News

From Our Own Representatives in Various Important Mining Centers

Washington, D. C.

The Interstate Commerce Commission has rendered its opinion in regard to the investigation and suspension of advances in rates by carriers for the transportation of soft coal from Illinois mines to stations on the St. Louis & Hannibal Ry. It now fixes through rates and joint through rates for the transportation of the coal over the road in question to Missouri points. The Commission says in part:

> Formerly the joint through rate from Panama to Hannibal, taking the latter as a typical point of destination, was 75c. a ton. Under the tariff of joint rates, which it is now proposed to cancel, the rate between those points is 82c. a ton. If this rate is withdrawn there will be available to shippers only the combination of local rates under which it is clear the traffic could not move. This result apparently was contemplated by the St. Louis & Hannibal in withdrawing its concurrence in the joint rates. As the withdrawal of the through rates, leaving in operation the lowest combination of local rates, would increase the charges on coal moving over that route, the defendants were under the burden of justifying their course and of showing that the resulting charges would be just and reasonable. But the record made at the hearing does not meet this requirement. In fact no effort was made to show that the combination of locals would be a reasonable charge on this traffic, nor was any substantial reason given for the cancellation of the joint through rates. We therefore find that rates in excess of those now in effect would be unjust and unreasonable.

Bureau of Mines Bill

After a lengthy debate on the Bureau of Mines bill offered by Representative Tooker on Wednesday May 29, the House of Representatives finally laid the measure on the table without passing it. The understanding is that the bill will be shortly taken up again and will then be passed. It is undoubtedly true that the opposition encountered by the bill is due to a fear that the measure would largely broaden the scope of the bureau's activity, and enable it to engage in mining operations on the public lands. Section 2 of the bill, which excited the greatest opposition and difficulty has, however, now been disposed of.

In advocating the measure, Representative Palmer of Pennsylvania probably expressed as well as any who spoke during the debate, the views of the advocates of the measure. Mr. Palmer said in part: "I want to say that so far as my observation has gone, and so far as I have learned from the people interested in coal mining especially, the work of this bureau, under the efficient and able management of its chief, Dr Holmes, has fully justified its creation. And although the time of its operation has been comparatively short, the work which it has done has fully come up to the expectations of those who devised the plan that resulted in the creation of this bureau. But, there are, as I intimated, other mining industries besides the coal-mining industry which are in need of the kind of service that this bureau has been giving in the coal-mining regions, and the present bill, as I understand it, is intended, in the creation of a new organic act for this bureau, to widen its jurisdiction and enlarge the scope of its work in order to include metal mining and quarrying."

Representative Fitzgerald took quite a different point of view, saying in part:

> Some three or four years ago the Frick Coal Co., of Pittsburgh, conducted a number of very important investigations to determine a number of matters of vital interest to the company in the conduct of its operations. It does so no longer. It permits the Bureau of Mines, at the expense of the Federal Treasury, to relieve it of the burden which formerly belonged to it.
>
> The primary object of the Bureau of Mines, one which should be kept in mind and from which we should not permit it to be diverted, is the protection of the men engaged in the mining industry, and by investigations to determine the causes of mine accidents, to outline methods by which accidents can be prevented, not only by the use of explosives that will not be hazardous to handle, but in proper shoring and working in the mines. But to investigate the economic conditions of these industries is to go much further.

The prospect now is that the Bureau of Mines bill will be passed in very much the form in which it was originally reported by the committee after amendment subsequent to its introduction.

Alabama

Birmingham—At a meeting of the preferred and common stockholders of the Alabama Consolidated Coal & Iron Co., held in Baltimore, May 31, announcement was made by Joseph H. Hoadley, former president of the company, but now chairman of the corporation, that Charles M. Schwab, president of the Bethlehem Steel Co., had promised to become financially interested in the Alabama Consolidated and to reorganize the company, provided the merger with the Southern Iron & Steel Co. should not go through. Facts also developed at the meeting which tend to prove that the efforts of the committee appointed about a year ago to merge the Alabama Consolidated Coal & Iron Co. and the Southern Iron & Steel Co. have proved fruitless, and the entire plan will likely be dropped.

Illinois

Mount Vernon — Prospectors working south of Mount Vernon have struck a 7-ft. seam of coal at a depth of 500 ft. A test has shown the coal to be of superior quality and it is understood that the field will be developed before long.

Chicago—Coal shippers along the Illinois Central lines as far south as New Orleans have protested against the new car apportionment plan put into effect by the railroad. This plan gages the supply of cars by the amount supplied by the road during the previous year. While the shippers claim that the new plan is radical and unjust the railroad officials declare that it was put into effect only after it had been found to be the most favorable to all.

Mt. Carmel—The Harrisburg mines, some of which have resumed operations since the recent shut-down, are reported to be shipping at the rate of 125 cars per day, and it is expected that this amount will be doubled in a very short time. This will be far short of a full output, but it is not anticipated that the business will be large until next fall.

Springfield—A recent meeting of the traffic managers of various railroads entering Springfield is expected to result in a reduction of 7 per cent in the freight rates to Eastern points. An urgent need of the coal men is an equitable rate to Chicago, it being claimed that Springfield is at a disadvantage of from 10c. to 20c. a ton as compared with points in Indiana. Relief in this latter particular, however, is not expected to be taken up until next month.

Bloomington—The first of a series of 52 damage suits against the St. Paul Coal Co. by widows and children of miners who lost their lives in the Cherry mine disaster of 1910 is being tried by the Bureau County circuit court. The aggregate of damages to be demanded is $400,000. The first case is that of Miles McFadden. This will be the test case, and it is estimated that it will require six weeks to complete it. The fate of the others probably will rest on the outcome of the McFadden suit.

Indiana

Terre Haute—The referendum vote taken recently by district No. 11, United Mine Workers, favored the acceptance of the proposed wage-scale contract by a substantial majority. The issue was in considerable doubt as there was evident a strong sentiment in favor of holding out for a weekly pay. The new contract provides for a semi-monthly pay, such as has been in force heretofore, and unofficial returns show that the vote stood 8007 in favor of accepting this provision and returning to work as against 3553 opposed to its acceptance. The new contract was signed May 31, and it was arranged that the men would return to work Monday, June 3.

Brazil—An effort is being made to organize the men employed at the stripping operations in this vicinity. A local union was recently established for two pits in the vicinity of Patricksburg and has become allied with the United Mine Workers.

Iowa

Des Moines—The mine workers of District No. 13 have ratified the agreement proposed at the recent joint conference of miners and operators. Despite the fact that the miner's convention declined to endorse the agreement, the referendum vote disclosed a large majority in favor of its acceptance. The mines are resuming work.

Kentucky

Maysville—The business of the Big Hill Coal Co. has been placed in the hands of John C. Chenault of Richmond, Kentucky, as receiver. The receivership is the result of a suit brought by John H. Jones to inforce mortgage claims against the property of the company in Lee and Bell counties. The suit is for $87,300. A restraining order was asked to prevent the State Bank and Trust Co., trustee; the New Straight Creek Coal Co., the Louisville and Atlantic Coal Co. and others from taking possession of the property.

Louisville—The newly organized Dean Coal Co., of Barbourville, has purchased the holdings of the Gibson-Carr Co., in the Brush Creek district of Knox County. The purchase includes over 1000 acres of coal lands and a recently installed mining plant. The company will begin operations at once.

The Interstate Coal Co., which recently purchased the holdings of the Cumberland Coal Co., now has investments of more than $1,000,000 in Knox county coal fields. Recently the company took over the holdings of the Bennett Coal Co. in the Brush Creek district, and it now owns all the mining operations in the Brush Creek field with two exceptions. Some time ago the Interstate Coal Co. purchased the Lunsford-Lawson-Detherage interests for $100,000.

Providence—A sale of the Fairmont Coal Mining Co.'s property was held here recently to dispose of the assets of the company which is in bankruptcy. The receiver rejected the bids which were offered on the ground that they were too low, and a private sale will probably be held instead.

Michigan

Bay City—An announcement was made, May 23, that the Michigan United Mine Workers and the operators had settled their differences and that the miners would return to work within a week.

Missouri

Kansas City—Coal operators and miners of the Southwestern district, after holding conferences in Kansas City for the last 60 days, have reached an agreement and a contract covering a period of two years has been signed. The agreement provides for a slight increase in wages. Miners and operators throughout Missouri, Kansas, Oklahoma and Texas are affected. The signing of the contract means that there will be no suspension in the coal fields of District No. 21 for two years unless something unforeseen develops. Had the agreement remained unsigned after May 31, a suspension would have followed. The contract expired Apr. 1 but provided for 60 days additional for negotiations.

Ohio

St. Clairsville—Fully 1300 miners were recently on strike in Belmont County. Six hundred men, employed by the Provident Coal Co., were out on account of trouble over a check-weighman; 450 at the mines of the Troll Coal Co. were out because they believed a member of the union was unjustly discharged, and at the Moore's Run mine of the Hutchinson Coal Co., at Bridgeport, 250 men were striking because they desired to ride to and from work on the motor trips.

The 600 men employed at the Provident mine, returned to work, June 3, as the company agreed to permit the employee selected by the men to go on the tipple. Three checkweighmen put on the tipple inside of three weeks by the company have been scared out of town by red flags and warnings that they would be killed.

Columbus—The U. S. Supreme Court, on May 27, reversed the Ohio railway commission and sustained the Wheeling & Lake Erie Ry. Co., in protesting against the establishing by the commission of a rate of 70c. a ton on what is called "lake cargo" coal, transported from the eastern Ohio coal field to Cleveland, Lorain and Huron. In sustaining the railway the supreme court affirmed the decision of the United States circuit court of appeals and settled one of the most important rate cases since the creation of the Ohio railway commission. The court ruled that transportation of "lake cargo" coal must be interstate commerce, saying: "The so called 'lake cargo coal' is necessarily shipped beyond Cleveland or Huron. If it stops there, another and higher rate applies."

Cincinnati—The Southern Retail Coal Merchants' Association will hold its annual convention in Cinciniati on June 12, and the Michigan, Ohio and Indiana Coal Operators' Association will meet June 12 and 13. The Kokoals will hold their national pow-wow at the same time.

Cambridge—The miners and operators in the Cambridge district have signed the scale for the coming two years and arrangements are being made to put the mines in full operation. Many are already being worked.

St. Clairsville—The Virginia Hill Coal Co., of Belmont County, has been placed in the hands of J. D. Jordan as receiver, as the result of a friendly suit instituted by the W. H. Pattison Supply Co. The company's affairs have been involved for some time and this method was taken to straighten them out. The authorized capital stock of the corporation is $700,000.

Pennsylvania

Bituminous

Irwin—The store and warehouse of the Berwind-White Coal Mining Co., at Herminie, a mining town near here, were destroyed by fire, May 29. The plant is a total loss and the whole town, which consists of miners' dwellings, was swept by the flames. Aid was asked from other towns.

Kaylor—There has been some trouble here, and more is expected on account of the eviction of striking mine workers from houses which belong to the Great Lakes Coal Co. The men have been out on strike since Apr. 1, demanding a wage scale in accordance with the Cleveland agreement.

Charleroi—Officials of the miners' organization are hopeful that the strike at the mine of the Clyde company, near Fredericktown, which has been in progress since Apr. 1, will be settled shortly. The men struck there for the scale agreed upon at the Cleveland convention, and the mine has been idle ever since. For the past four years the mine has been operated nonunion. The operators have made some concessions, but the men are standing out for the scale as paid elsewhere in the district.

Dubois—Kelly brothers, who recently purchased the holdings of the Richmond Coal Co., and are now busy at work get-

ting the plant at Savan in shape for active operations, a few days ago purchased 100 acres of land adjoining their property on the southeast. The price paid was reported as $70 per acre.

Johnstown—The Blue Bird shaft, of the Portage Coal Mining Co., was completely flooded as the result of the bursting of a water main, May 27, and over 250 miners were thrown out of work. It was announced that work would not likely be resumed for several days.

Although the coal market is a trifle dull, the Greenwich Coal & Coke Co.'s operations, in Somerset County, have been running steadily every day and the contracts are of such a nature that the company assures the men that very little, if any, idle time may be expected during the coming summer. New men are being employed every day. Mine No. 8, near Shankstown, which had been shut down for about two years, was reopened, May 20.

About 200 new dwellings are being erected by the Consolidation Coal Co., at Acosta. The company has an extensive coal field in this section and has a large opening in operation at present, with an output of about 1500 tons daily.

Connellsville—Freight rates on coke from this district shipped to Youngstown and other sections were attacked as too high before the Interstate Commerce Commission, May 27, in hearings on complaints of the Youngstown Sheet & Tube Co. and others against the Pittsburgh & Lake Erie R.R., and the Connellsville Coke Producers' Association against the Baltimore & Ohio, the Pennsylvania and other railroads. That the independent iron and steel producers of the Youngstown district of Ohio and western Pennsylvania will be compelled to build a railroad from the Connellsville coke district through several of the iron and steel districts with a terminal on Lake Erie, unless there is a reduction in the rate on coke, was a statement made by James A. Campbell, president of the Youngstown Sheet & Tube Company.

Anthracite

Scranton—Allegations that certain of the union leaders at the Oxford colliery of the People's Coal Co., at Scranton, have not been reinstated in their positions because of their activity in connection with the union, may lead to a strike. There was no union at the colliery until the recent suspension, during which the mine worked but little, although it ran at full blast during the 1902 strike. The company maintains that it has merely refused to discharge men who worked during the suspension in order to employ others who did not.

About 400 men and boys employed at the Fernwood slope of the Hillside Coal & Iron Co., struck recently and refused to return to work until certain grievances were adjusted. The men are employed under the supervision of two contractors and are paid by them. The miners demanded that the contractors be removed, as they claimed they could make more money working directly for the company.

The organization of the committee which is to investigate the advance in prices of domestic anthracite under the auspices of the New York Merchants' Association has been completed and it is expected that the investigations will be commenced at an early date.

Wilkes-Barre—A gas explosion in the Pettibone mine of the Delaware, Lackawanna & Western Co., early, May 28, injured four men. Two were thought to be dying when taken out. With the aid of the local rescue corps, 60 other miners made their escape without injury.

It has been announced that all the large anthracite coal companies will make a flat 10 per cent. increase in the wages of their hoisting engineers, thus bringing their rate on a par with the other mine workers. Indications were that some of the companies would grant only a 5 per cent. increase while others did not seem disposed to grant any and no little disappointment was felt in consequence.

Hazleton—At the offices of the United Mine Workers here, it was given out that the wages of all carpenters employed about the coal mines will benefit by the 10 per cent. increase recently granted the other men. Most of the carpenters were members of the union of that trade in this city and were surprised to learn that they will share in the advance. In doing so, however, they become subject to the union jurisdiction of the miners and are being asked to joint that organization.

Resumption of work at the mines has been marked in this as well as in other regions by a number of local strikes, chiefly with the object of bringing non-union workmen into the organization. Strikes of this nature took place recently at Coleraine and at the Hazleton Shaft colliery of the Lehigh Valley Coal Co.

Utah

Provo—The railroad from Helper to the coal lands in Carbon County, owned by the Knight interests, is now assured, and it is given out by the engineers in charge that the road will be in operation by next fall. A fully equipped coal-mining camp will be established and in readiness to ship coal by the time the road is finished. The road is to be run from Helper, on the main line of the Denver & Rio Grande, to the coal beds, a distance of 4½ miles, and will cost upward of $250,000, aside from the rolling stock. Right-of-ways have been secured and everything is now in readiness to begin the building of the road, and the contract for its construction is to be let at an early date.

Washington

Spokane—A. B. Ward has announced that he will form a company to develop his coal property at Peone prairie. Work will be started this summer. Mr. Ward states that he is confident that coal will be found in large quantities.

West Virginia

Charleston—Striking miners of the Paint Creek Colliery Co., at Mucklow, Md., attempted to massacre a dozen Baldwin mine guards, May 31. One hundred shots were fired at the unarmed detectives *enroute* from their sleeping house at the mines to their boarding house for breakfast. All escaped but one, who was wounded in the side. The injury was not fatal. The miners at Paint Creek are the only ones in the state on strike, having refused to accept the scale agreed upon.

A big coal development will be started by the Berwind-White interests in Fayette County within the next few weeks. The land to be developed lies between Pack's Branch and Paint Creek, in the Fayetteville district. The tract contains 6000 acres, and was purchased by the Berwind-White interests from the McKinley Land Co. This development has been under contemplation for two years or more. Already a number of houses are being constructed, some of which will be completed within the 30 or 40 days.

Wheeling—The joint conference scale committee of the miners and operators of eastern Ohio reported to the general conference, May 31, that they were unable to reach an agreement. Differences must be adjusted by the conference itself.

Williamson—The United Thacker Coal Co. has increased its holdings in West Virginia from 8,000 to 65,000 acres. Under the West Virginia law a corporation can hold up to 10,000 acres without paying a special tax. The United Thacker Coal Co. now pays a special tax on 55,000 acres in this state.

Wyoming

Kemmerer—Work on the new mine of the United States Coal Co., at Adaville, is progressing favorably. The name of the camp has been changed to Conroy. A new steel tipple has been ordered and will be installed as soon as the railroad is completed, work on which will begin early next month, the track being laid over the old grade from Moyer. It is expected that the shipment of coal will commence about the first of September.

Canada

Edmonton, Alberta—All the buildings belonging to the Western Coal Co., at its mine in the Clover Bar mining district, were destroyed by fire, May 26. Loss, $75,000.

Personals

John F. Chilcott, superintendent of construction for the Allegheny River Mining Co. Kittanning, Penn., has resigned, effective June 5.

Eli T. Conner, consulting mining engineer, of Philadelphia, Penn., is making a business trip to Newfoundland where he will remain for a week or ten days.

G. W. Seiler, formerly with Pattison & Bowns, at No. 1 Broadway, New York, is now in charge of the anthracite department of the A. W. Hillebrand Co., at the same address.

C. V. Gould, general manager of the United States Coal Co. recently spent several weeks at Adaville, Wyo., looking after the development of the company's new mine at that point.

W. R. Crane, dean of the School of Mines, Pennsylvania State College, will leave for Alaska about June 15, and will spend the coming year studying the mineral resources of that country.

Henry L. Badham, of Birmingham, Ala., president of the Bessemer Coal, Iron & Land Co., is spending a few weeks traveling in Europe. William S. Lovell, vice-president, is looking after Mr. Badham's duties during his absence.

P. W. Turner, mine foreman for the state of Alabama, at the Banner mine of the Pratt Consolidated Coal Co., which is operated with convict labor, by the state, has been appointed by Gov. O'Neal, superintendent of the mine, effective at once. Mr. Turner succeeds William L. Martin, whose resignation was announced a short time ago.

S. D. Warriner, vice-president of the Lehigh Valley Coal Co.; W. J. Richards, vice-president of the Philadelphia and Reading Coal Co. and W. L. Connell, of Scranton, an independent operator, have been reëlected as representatives of the anthracite operators on the board of conciliation provided for by the anthracite strike commission of 1902.

Effective June 1, 1912, the following changes have been made in the operating department of the Lehigh Valley Coal Co., Wilkes-Barre, Penn.: J. M. Humphrey, formerly division superintendent of the Mahanoy and Shamokin division, with headquarters at Centralia, has been appointed mining engineer, with headquarters at Wilkes-Barre, vice A. B. Jessup, who recently resigned to become general manager of the G. B. Markle & Co. properties at Jeddo. H. J. Heffner, formerly division engineer of the Mahanoy and Shamokin division, has been appointed superintendent of that division, vice J. M. Humphrey, transferred. G. P. Troutman, formerly division engineer of the Lackawanna division, Pittston, Penn., is appointed assistant superintendent and engineer of that division.

Obituary

Frank E. Lukens, secretary of the Illinois and Wisconsin Retail Coal Dealers' Association, committed suicide in the Best Hotel, Chicago, May 27. Threatened governmental investigation of retail fuel associations, which had resulted in the withdrawal of a number of members from the one in which Mr. Lukens was interested, is said to have been the cause of his act, although the organization of this association thoroughly conforms with the law. Mr. Lukens was exceptionally well known in retail coal circles.

Construction News

Marion, Ill.—The Big Muddy Fuel Co. is receiving bids for a washer of from 300 to 500 tons capacity, to be built at their mine north of here.

Big Stone Gap, Va.—C. B. Slemp and others of this section are considering the development of coal property near Hazard, Ky. Among those interested is John C. C. Mayo, of Paintsville, Ky.

Pineville, Ky.—The Moss Coal Co. has leased a tract in Letcher County, near Whitesburg, and will open a mine at once. The mine will be located on the extension of the Lexington & Eastern R.R., which is now being completed.

New London, Conn.—Bids will be received until June 15, by Capt. F. T. Arnold, for constructing, at Fort Terry, N. Y., a coal-handling and storage plant, consisting of frame building with concrete floor and footings, industrial railway, motors, etc.

Whitesburg—The Mineral Development Co., of Philadelphia, has announced plans for the construction of coking plants near the head waters of the Kentucky River, in Letcher County. The plant will be reached by the extension of the Lexington & Eastern R.R.

Brownsville, Penn.—The contract for new construction work at the plant of the Lilley Coal & Coke Co., has been awarded to the Dravo Contracting Co., of Pittsburgh. This contract was erroneously reported as awarded to the Drake & Straton Co., of Pittsburgh.

Birmingham, Ala.—The Central Coal Co. has announced that it will expend about $100,000 in improving its property in the Warrior coal field. The work will include a modern tipple, new electrical equipment, coal-cutting machinery and a system of haulage in the mines. B. F. Roden, Birmingham, is president.

The Woodward Iron Co. has awarded a contract for the construction of a coke bin of about 500 tons capacity.

Chattanooga, Tenn.—The Durham Coal & Iron Co. is negotiating for the purchase of a large body of mineral and timber land in Sequatchie Valley, on the Southern R.R., and will expend $5,000,000 in developing the property and increasing facilities. The land is rich in iron ore, coal and timber. This company plans to erect a large steel mill, several blast furnaces, coke ovens and byproduct plants. The principal industrial plants of the company will be located at Moccasin Bend, all of which land the company recently acquired.

The Chattanooga Coal & Iron Co. contemplates installing a battery of 60 Koppers byproduct coke ovens.

Publications Received

JOURNAL OF THE WESTERN SOCIETY OF ENGINEERS, May, 1912. 95 pp., 6x9 in., illus. 50c. Office of the Society, Chicago.

SUPERHEATED STEAM IN LOCOMOTIVE SERVICE. By W. F. M. Goss. Bulletin No. 57, University of Illinois. 66 pp., 6x9 in., illus. 40c.

The bulletin presents in abridged form information which originally appeared as Bulletin No. 127 of the Carnegie Institute of Washington.

THE USE OF PERMISSIBLE EXPLOSIVES. By J. J. Rutledge and Clarence Hall. Bulletin No. 10, U. S. Bureau of Mines. 34 pp., 6x9 in., illus. Government Printing Office, Washington.

Investigation has shown that one of the commonest causes of disastrous explosions in the coal mines in this country has been blown-out shots of black blasting powder or dynamite. The dangers that attend the use of these explosives were perceived several years ago, and in consequence the attention of powder manufacturers was directed to the production of explosives that would be less liable to ignite inflammable gas or dust. The manufacturers have been so successful in their efforts that it is now possible to obtain explosives which yield much shorter and quicker flames than black blasting powder or dynamite, and hence are much less dangerous to use in fiery or dusty coal mines. An explosive is termed a permissible explosive when it is similar in all respects to a sample that has passed certain tests by the Federal Bureau of Mines.

The bulletin describes the proper methods of using these explosixes with some notes on electric shot firing, undercutting and drilling. The characteristics and advantages of the permissible forms are explained and it is noted that the cost of blasting per ton of coal is only slightly increased by their use if indeed there is any increase at all.

Storage for Explosives, pamphlet, 27 pp., 6x9 in., illus. High Explosives, pamphlet, 136 pp., 6x9 in., illus. These publications, in addition to describing and listing the products of the Du Pont company, contain much interesting and valuable information relative to explosives, handling, storing and using the same.

Coal Trade Reviews

Current Prices of Coal and Coke and Market Conditions in the Important Centers

General Review

During the past week the anthracite trade has continued the predominating feature in coal circles. The advance in prices on domestic grades has resulted in much bitter opposition on the part of the consumers, who at some points are forming associations for the purpose of investigating the hard-coal companies, with a view to restraining them from the new increase.

As we predicted, the anthracite advance was confined almost entirely to the domestic grades, it being impossible to increase the steam sizes because of the competition in this trade with the soft-coals. Since it was thus feasible to advance quotations on only a portion of the product, it was necessary to make this unusually heavy, which has excited much unfavorable comment.

In the Eastern market there is considerable soft-coal coming forward, which is being offered at liberal discounts from the nominal prices. Spot business generally is dull, although probably about normal for this period of the year, and the market promises to be slow and heavy for the next two months. The Pittsburgh district reports a heavier demand now than at any time since the suspension; stocks appear to be about worked off, and some operators are producing up to nearly full capacity, the demand from the Lakes being particularly heavy.

In Ohio the Lake demand is the best feature of the trade, and there is some evidence of improvement in the steam sizes, although prices still continue low. Business has eased off in West Virginia, but there has been a heavy movement to the Lakes and the West, and operators are holding firm on prices. Railroad congestions, due to the flood in the Mississippi Valley, has interfered with the movement from Alabama and resulted in a slowing down in production there.

The Middle Western market continues slow and heavy, except Indiana. An agreement between the miners and operators has finally been effected there, which will probably result in at least a temporary heavy production until the district catches up on its orders.

Boston, Mass.

The stand taken by certain of the New River interests in sticking to $2.70, f.o.b. loading port, be the tonnage large or small, is a favorable sign. Until all take this attitude, however, not much improvement can be expected in the price situation. An amount of coal is still coming forward on a liberal discount off the nominal price, and no change is in sight, in that respect. The prediction that June and July were likely to be dull in bituminous need not be changed.

On the Pennsylvania grades it develops that there will still be anthracite transportation available for this market. Hard-coal is coming down so slowly that the roads with floating equipment are bound to be in the soft-coal freighting business to a certain extent, and this will keep outlet open to coals from the Pennsylvania districts and Georges Creek that would ordinarily be served from Hampton Roads.

Anthracite shipments began from Philadelphia the week of May 27, but only in small volume. Some of the collieries are up to but 50 to 60% of normal efficiency. Taking this, together with the reported withdrawal from the tide market of certain of the anthracite companies, and their general inactivity at this time, the Eastern dealer is going to have difficulty in getting his coal.

Wholesale prices are about as follows:

Clearfields, f.o.b. mine	\$1.10 @\$1.35
Somersets, f.o.b mine	1.20 @ 1.35
Clearfield and Somersets, f.o.b. Philadelphia	2.35 @ 2.60
Georges Creek, f.o.b. Baltimore	2.77 @ 2.87
Pocahontas, New River, f.o.b. Hampton Roads	2.70
Pocahontas, New River, f.o.b. cars Providence	3.40 @ 3.50
Pocahontas, New River, f.o.b. cars, Boston	3.40 @ 3.60

New York

Anthracite—Arrivals of hard coal continue to come in slow, and the mines are reported to be working only about 50 to 60 per cent. capacity. No orders are being accepted by the large companies for stove except for July deliveries, and the Nos. 2 and 3 steam grades are short in supply, although there is plenty of the No. 1 available.

Consumers are not buying to the extent that was expected, due probably to the hope that the investigation now being conducted by the merchants' association will result in a reduction in prices on the domestic sizes. The larger companies, however, report an active demand from the dealers, and it is evident that the latter are replenishing their depleted stocks as rapidly as possible in anticipation of an active demand during the fall and winter.

The following are the wholesale f.o.b. quotation, those for the Lackawanna and Wyoming being at the upper ports and the Lehigh and Schuylkill for the lower:

	L.&W.	L.&S.
Broken	\$4.70	\$4.65
Egg and stove	4.95	4.90
Chenstnut	5.20	5.15
Pea	3.50	3.45
Buckwheat	2.75	2.45
Rice	2.25	1.95
Barley	1.75	1.70

Bituminous—Last week is said to have been one of dullest in the history of the soft-coal market here; this is not, however, unusual for this period of the year. On the whole, the trade is holding up as well as could be expected at this time, and indications are for an active business this fall. Supplies are being worked down some and tonnages will probably show some improvement soon, although it is doubtful if there will be any advance in prices. Stocks on hand at South Amboy are quite large, and there are rumors of embargoes being declared there. Same contracts are being closed at an advance over last year's figures.

We continue to quote prevailing wholesale prices as follows, although there is some shading from these:

West Virginia, steam	\$2.35
Ordinary grades, Pennsylvania	2.45
Fair grades, Pennsylvania	2.55@2.65
Good grades, Pennsylvania	2.70@2.80
Best Miller, Pennsylvania	3.00
Georges Creek	3.15

Pittsburgh, Penn.

Bituminous—Manufacturing demand has improved, and is better than at any time since before the suspension of mining. The stocks seem to have been practically all worked off. Shipments in the Lake trade are now very heavy, with a good supply of vessels. Operations in the Pittsburgh district on an average are much heavier than a fortnight ago, having been steadily increasing; the Pittsburgh Coal Co. reports that it is operating up to its capacity. Prices are quoted on the regular season basis, though they are occasionally shaded, particularly on slack: Mine-run and nut, \$1.22½; ¾-in., \$1.32½; 1¼-in., \$1.47½; slack, 82½c. per ton at mine, Pittsburgh district.

Connellsville Coke—Active negotiations continue for furnace coke for second-half delivery, and prices are firm. None of the sellers are asking less than \$2.50, and some more. In exceptional cases, where the buyer is certain of taking deliveries under unfavorable market conditions, the \$2.50 price might be

shaded a trifle. Thus far between 40,000 and 50,000 tons a month have been placed under contract for the second half, at from $2.35 to $2.50, and there remains to be covered probably about 100,000 tons a month. Sales of about 35,000 tons of furnace coke for June delivery have been made at from $2.25 to $2.35, but occasionally $2.25 is shaded for prompt shipment. Foundry coke is somewhat stiffer, particularly on contract. We quote: Prompt furnace, $2.20@2.30; contract furnace, $2.40@2.50; prompt foundry, $2.35@2.50; contract foundry, $2.40@2.75.

The *Courier* reports production in the Connellsville and lower Connellsville region in the week ending May 18 at 394,316 tons, a decrease of 4640 tons, and shipments at 4194 cars to Pittsburgh, 6467 cars to points west and 1132 cars to points east, a total of 11,793 cars, or a decrease of 149.

Philadelphia, Penn.

Taking the coal trade as a whole, the last week has not been altogether propitious in this locality. It is true that some coal is moving off, notably stove, chestnut and pea sizes, but as for an actual, insistent demand, which, as a rule, characterizes the month in which the lowest prices are announced, it is not present. There is considerable space in the papers devoted to articles about investigations into the advance in prices, and the attendant agitation which it brings about has its effect in causing householders and others to delay making purchases, but it would seem that this is altogether unnecessary, as the raise in prices is only what was to be expected.

The wholesale market is good, particularly at tidewater. It is understood that the companies are well supplied with orders for Eastern and Southern ports, and are only hampered in shipment by the lack of vessel facilities.

Bituminous conditions have not in the least improved, and compare with the very serious setback this branch suffered during last summer. The determination of the anthracite miners to resume work destroyed any hope that may have been felt that conditions would improve, and until stocks of coal, accumulated earlier in the year, are disposed of, there is little to look forward to.

Baltimore, Md.

Although one or two of the larger companies are reporting an active demand, the smaller operators claim that the Baltimore market, so far as they were concerned, is dull. There is only a fair demand for the product, and low prices prevail. Many Baltimore companies depend largely on spot orders, because there is more profit in such sales, and this business has been conspicuous by its absence and with no indications of improving.

Of course, coal is moving under existing contracts, which were placed some time back by companies that consume fuel steadily month in and month out, and it is safe to say that nearly all of the coal in which the local trade is concerned, is moving under contract.

The Consolidation Coal Co. is now operating seven of its new mines opened in the Elkhorn Valley of Kentucky, and the product is being stored to be shipped when the railroad now under construction is completed, which will be in August.

Buffalo, N. Y.

There is no improvement in the demand for bituminous and none is looked for right away, as there is still too much coal in the consumers' hands, bought before or during the early part of the suspension. There are a few consumers getting to the end of their supply, but there are mines starting up and quite likely turning out more coal than the increased consumption demands.

Sometimes there is such a demand for slack at this period of the year that it insures a fair profit for everything, but such is not the case now; the slack market is not nearly as good as during the past two summers. Consumption is at least fair, but there is too much coal; all effort to restrict the production of bituminous fails and there is now no further talk of this.

The price of bituminous coal is weak at former bottom quotations, $2.57½ for Pittsburgh three-quarter, $2.47½ for mine-run and $2.10 for slack, with Allegheny Valley 15 to 25c. lower. Coke is very quiet at former figures, based on $4.25 for best Connellsville foundry.

The movement of anthracite began about May 27, when water tonnage for the upper lakes was first loaded this season. There is complaint that miners are scarce, but 54,000 tons being loaded in four days and this chiefly by a single company. That branch of the business will be very active for the rest of the season and efforts will be made to wipe out the lead of 600,000 tons which last season has over the present one.

Cleveland, Ohio

There has not been any improvement during the past week in the coal business, and only a small amount has been shipped to this market on consignment, which it has been found very difficult to dispose of. Coal has remained on track for a week or more with car service accruing and without any chance of disposing of same. There still seems to be considerable left over from purchases made prior to the strike, and general business in the manufacturing line does not seem to improve to any extent.

There is a very small amount of coal coming forward for the Lake trade. Buyers seem to be holding off in placing contracts, and the few fortunate ones that have made contracts cannot run their mines to full capacity on account of the lack of men.

Columbus, Ohio

The coal trade in Ohio during the past week was rather active, despite the fact that a holiday broke in and curtailed production to a certain extent. With the exception of domestic grades, there was a considerable production in most of the Ohio fields and the outlook for the future is considered good. While prices are still low and will probably remain so for some time, improvement in that direction can be expected toward the latter part of the summer.

There is some activity in steam grades, due to the fact that certain manufacturing establishments still have a surplus interfering with new orders. Business generally is fair and the requirements for steam purposes are good, although the movement is not large. There is some renewing of steam contracts at the price prevailing last season, plus the added cost of mining.

Considerable interest has been directed toward certain railroad contracts which will be awarded within the next week or 10 days. A number of the larger producers are strong after these contracts, which are among the largest in this section. Among the contracts to be let are the New York Central, the Ann Arbor and the Piere Marquette.

Prices which prevail in Ohio are as follows:

Hocking Valley	
Domestic lump	$1.50
¾-in	1.35
Nut	1.15
Mine-run	1.15
Nut, pea and slack	0.75
Coarse slack	0.65
Pittsburgh No. 8	
Mine-run	1.10
¾-in	1.20
Coarse slack	0.70
Pomeroy Bend	
Domestic lump	$1.50
¾-in	1.35
Nut	1.20
Mine-run	1.15
Nut, pea and slack	0.75
Coarse slack	0.50
Kanawha	
Domestic lump	1.50
¾-in	1.30
Nut	1.15
Mine-run	1.10
Nut, pea and slack	0.75
Coarse slack	0.65

Hampton Roads, Va.

There has been little activity at Hampton Roads during the past week. Shipments from the mines have been light, thus keeping down the stock of coal at the three piers; a heavy tonnage has been moving West and to the Lakes.

Some interest was aroused by the arrival of the German fleet, Thursday morning, the interest reaching an acute stage when it was learned that the coal for the

three vessels constituting the fleet would not be furnished by local shippers. No better steamship fuel can be obtained at any port in the country than that furnished by the Hampton Roads shippers, who were confidently relying on bunkering the German fleet.

Dumping figures for the month of May do not show up as well as the previous month; in fact, this could not be hoped for. The Norfolk & Western piers again lead with 523,071 tons (over two million tons having been loaded on that line during May, the highest figure ever reached by them); Chesapeake & Ohio Ry., 370,055; and the Virginian Ry., 189,689, the later piers dumping some thirty odd thousand tons more than in April in spite of the general decrease in dumping.

Charleston, W. Va.

Conditions remain good in West Virginia, especially in the southern and central districts. As yet there has been no letup in the supply of cars, but operators fear a change in this respect. More mines are in operation this week than there were last week. A number of the operations owned by the Paint Creek Collieries Co., employing about 1500 men, which have been idle since shortly after the first of April, are now in operation, but only a small number of men are at work. The mines are being operated by nonunion men.

Lake shipments, while heavy, are giving the shippers some concern, owing to the congested conditions both at the Lakes and along the Hocking Valley road, extending into the mining region in the Kanawha district. Lake shipments have moved with considerable speed, due to the abundant motive power.

Prices have been fair, the expected falling off, usual at this time of year, having not materialized and no drop is anticipated in the immediate future.

Birmingham, Ala.

The past week has developed a dull market for Alabama coal and the prospects are not considered so bright as they appeared some days ago. Coal operators have failed to show a firm front and as much as 10c. off per ton has been quoted during the week.

The extremely warm weather which has prevailed during the past week is considered an important factor. It is also probable that the shutting off of shipments to Mississippi River points and the West by the flood resulted in a temporary congestion and surplus, which, it is hoped, will be overcome as normal conditions return.

All of the mines are operating full time with the exception of a few of the smaller ones, which have lost a day or two during the past week. Some of the operators are even complaining of a difficulty in getting sufficient mine labor. The iron-furnace companies that engage in coal mining are demanding labor more than others. The coke market is feeling the dull period but prices are maintaining a fair front.

Nashville, Tenn.

We are having our usual period of summer dullness in this field. In fact, it is duller than usual, which is strange in view of the fact that the Indiana miners have not returned to work, and the union fields of western Kentucky have only been at work two weeks. This clearly indicates what has been felt for some time—that there is a vast over-production of coal in our section.

Though there is no business at any price, and some of the operators have gone down to their usual cost of production quotations, the majority are not trying to create a demand. They know that it does not exist at low prices and are using their best efforts to keep quotations up so as to enable them to obtain better prices for their product after Aug. 1. It remains to be seen whether or not this can be accomplished.

There is no demand for lump at any price and mine-run is being offered from 75@85c., nut $1.10@1.25, and 1⅛-in. screenings 40@50 cents.

Indianapolis, Ind.

The resumption of coal mining in Indiana, after a suspension of two months, during which time numerous meetings and conferences were held without avail, is hailed with delight by the miners, operators and the country in general.

The Indiana mines all resumed work Monday, June 3, under a new wage scale with a slight advance, and it is believed there will be work enough for every miner in the state. Orders have been piling up at the mines, and if the railroads handle the product, some large outputs will be made.

There is a difference of opinion among the retail dealers relative to an advance of 25c. a ton on coal. Some of the dealers say it would be an outrage at a time of general unrest and discontent, due largely to the cost of living and the unprecedented long and cold winter.

Chicago

The price of anthracite advanced 25c. a ton June 1. No open antagonism has been shown, so far as the increase is concerned, but the buyers believe it a wise policy to await the outcome of the fight begun by Eastern retailers against the advance.

With the opening of the Indiana mines, Illinois operators are now preparing to fix the price on several large contracts, which will have an exceptionally important bearing on bituminous prices generally. Screenings are scarce, current prices ranging all the way from $1 at the mines to $1.10 for spot coal. Smokeless coal has not been abundant on the spot market and prices are firm.

Prevailing prices at Chicago are:

Sullivan County	
4-in. lump	$2.47
Egg	2.37
Steam lump	2.99½
Screenings	1.87@1.97
Springfield	
Domestic lump	$2.32
Steam lump	2.07
Mine-run	1.97
Screenings	1.97
Clinton	
Domestic lump	$2.27
Steam lump	2.12
Mine-run	1.92
Screenings	1.77@1.87
Pocahontas and New River	
Mine-run	$3.15
Lump and egg	3.55

Coke—Prices asked for coke are: Connellsville and Wise County, $4.75; byproduct, egg and stove, $4.65; byproduct, nut, $4.55; gas-house, $4.75.

Minneapolis—St. Paul

The coal trade in the Twin Cities has shown very little activity during the past 10 days. Coal men cannot figure out why the market is not stronger than it now is with Indiana not working, and only about 50 per cent. of Illinois mines in operation. Coal is coming up to the head of Lakes slower than usual and with these conditions there should be a better market.

Should but 75 per cent. of the crop prospects materialize it will create a condition with which the transportation companies will find it a physical impossibility to cope with. A number of railroads in this territory are already beginning to call in their rolling stock.

Coal men report some steam business but say that contracts are being closed at extremely low prices, a number being let at $3.25 for Youghiogheny, and it is rumored the price is as low as $3 at the head of the Lakes. Prices are out for June 1 on hard-coal on the basis of $7 for nut; $6.75 for stove and egg, and $5.75 for pea sizes.

St. Louis, Mo.

The market in St. Louis is intensely dull. There is no demand for coal and the only business in sight is the few contracts that are being let.

There is one order in St. Louis that calls for 200 tons of mine-run coal per day. Destination weights govern settlement, and in the past it is understood this contract brought $1.05 on a mine basis for a mine-run coal. The contract has not been awarded as yet, but some of the bidders have quoted as low as $1.02½ it is rumored; yet they claim that it costs them from 12c. to 15c. per ton more to produce coal this year than last.

The storage stocks around St. Louis are being cleaned up, and it is likely that there will be a small demand for steam coal about June 15. Illinois mines are

gradually resuming, but all the operators claim they are working at a loss. The prevailing prices are:

Carterville	
Lump and egg	$1.25@1.35
Nut	1.20@1.30
Mine-run	1.05@1.15
Screenings	1.05@1.10

Franklin county coal prices rule about 10c. higher than the above.

Mount Olive	
2-in. lump	$1.25
2-in. screenings	1.05
Standard	
2-in. lump	$0.85@0.90
2-in. screenings	0.85@0.94
1x2 nut	0.85@0.90
Mine-run	0.85@0.94

A heavy tonnage of anthracite orders was placed the past week, stove leading the others. The market for June, St. Louis, is: Chestnut, $7.15; egg and stove, $6.90; grate, $6.65. There is very little coke moving forward.

Portland, Ore.

There is absolutely no change in the coal situation here; the market is dull and little is expected till people begin putting in supplies for next winter. This movement will probably begin next month. The Consumers' Coal Co. is a new concern doing business here, selling wholesale and retail, and it deals principally in Wellington coal.

Freights from Australia are very high this year, and it is doubtful if there will be much coal imported early in the season from that source unless charter rates show a material reduction. This is not considered likely, however, unless ship owners find very remunerative business out of the Northwest when the wheat begins to move.

Production and Transportation Statistics

The Virginian Ry.

Total shipments of coal over this road for April of the current year amounted to 280,995 short tons.

The Car Situation

The ending of the strike among the miners in the anthracite district brought about a sharp reduction in the number of idle cars reported by the American Railway Association as of May 23. The total net surplus on that date was 116,-201, as compared with 130,008 reported two weeks earlier.

The following table shows the surplus and shortages of cars on 163 roads on May 23 last:

	Surplus	Short	Net Surplus
Box	23,298	2,918	20,380
Flat	4,053	1,618	2,435
Coal, gond. and hopper	71,068	2,649	68,419
Other kinds	25,264	297	24,967
Total	123,683	7,482	116,201

Pennsylvania Railroad

Statement of coal and coke carried on the P. R.R. Co.'s lines east of Pittsburgh and Erie during April and the first four months with the increase or decrease over the same period last year, in short tons:

	April	4 mos.	Difference
Anthracite	290,865	3,579,602	— 587,210
Bituminous	3,291,985	15,461,920	+2,157,985
Coke	1,079,046	4,190,832	+ 550,958
Total	4,661,896	23,232,354	+2,121,733

Baltimore & Ohio R.R.

The following is a statement of the coal and coke tonnage moved over the B. & O. and affiliated lines during the month of April, 1912, as compared with the corresponding month of the previous year:

	1911	1912
Coal	2,053,085	2,122,285
Coke	337,183	390,228
Total	2,390,268	2,512,513

Coal Exports

According to figures just issued by the Department of Commerce and Labor, Bureau of Statistics, our coal exports rank eighth in importance, for the ten months ending with April of this year. The following is the value of our export trade in millions of dollars:

Raw cotton	585
Iron and steel manufacture	260
Meat and dairy products	160
Breadstuffs	135
Copper	110
Mineral oil	100
Lumber, etc	90
Coal	50

Norfolk & Western Ry.

The following is a comparative statement of the coal and coke shipments over the lines of the N. & W. Ry. for the months of April, 1911-12, in short tons:

Destination	1911	1912
Coal		
Tidewater, foreign	90,562	223,220
Tidewater, coastwise	212,279	313,076
Domestic	1,063,887	1,325,259
Coke		
Tidewater, foreign	8,132	7,744
Domestic	138,997	108,601
Total	1,513,857	1,979,900

Foreign Markets

Great Britain

A better inquiry has set in, and the market shows signs of improvement for June shipments. Prices are approximately as follows:

Best Welsh steam coal	$4.38
Seconds	4.20
Thirds	3.90
Best dry coals	4.26
Best Monmouthshire	3.84
Seconds	3.66
Best Cardiff small coal	2.42
Seconds	2.38

The prices for Cardiff coals are f.o.b. Cardiff, Penarth, or Barry, while those for Monmouthshire descriptions are f.o.b. Newport; both exclusive of wharfage, and for cash in 30 days, less 2½ per cent.

Spanish Imports

Spanish imports for the three months ended March 31, chiefly from Great Britain were as follows in metric tons:

	1911	1912
Coal	473,539	614,593
Coke	83,156	108,669

The Chinese Market

There has been another quiet fortnight on this market and although a few small contracts have been concluded there is very little demand locally and only small inquiry: forward, there is, however, a better feeling among native dealers and banking facilities are now easier, but money is still very tight. Prices are steady but freights are ruling high and are likely to remain so for some time.

Manchurian Coal—Stocks continue to decrease owing to the scarcity of tonnage.

Kaiping Coal—The usual deliveries have been made under contracts but there is not much new business to export. Prices remain steady and firm.

Financial Notes

Consolidation Coal Co.—Operating expenses of this company for **1911** were $8,467,662, as compared with $9,186,013 for the year 1910. Plant depreciation for 1911 was $221,618, as compared with $251,410 for 1910.

American Coal Products Co.—The $1,250,000, 5% serial gold coupon notes of 1910 of this company have been called for redemption and will be paid by the Guaranty Trust Co., of New York, at par and interest on presentation on or before June 1.

The Delaware & Hudson Co.—From the sale of $7,000,000 additional first and refunding mortgage gold bonds mentioned in last year's report, this company realized $6,825,000; the discount of $175,-000 was charged to profit and loss. The floating debt was decreased $3,594,320 during 1911.

Colorado Fuel & Iron Co.—Earnings of this company for the first eight months of the present fiscal year are about $126,000 in excess of those for the corresponding period of 1911, and indications are that the surplus for the year ending June 30 will approximate $1,500,000. This will be a substantial improvement over last year's surplus of $1,260,000.

Alabama Consolidated Coal & Iron Co.—The interest on the $2,084,000 consolidated 5's due May 1 has been defaulted. President Hoagley explains that, after consultation with Harvey Fisk & Son, who are managers of the syndicate which will underwrite the new securities to be issued under the plan of merger with the Southern Iron & Steel Co., it has been decided to take advantage of the clause which gives the company 12 months in which to meet interest before foreclosure proceedings can be brought.

Woodward Iron Co.—On the basis of past years this new corporation should start by earning annually at least $1,000,-000, which will be sufficient to meet all charges of dividend requirements. A sinking fund, commencing 1917, is provided on the basis of 3c. for every ton of coal mined with a minimum for each year for ½ of 1% on the total principal amount of bonds outstanding. It is further provided that after 1939 the minimum shall be increased sufficiently to retire the remaining bonds at or before maturity.

Insurance of Mine Officials in the Ruhr District and the Insurance Law for Employes. (Die Grubenbeamtenversicherung im Ruhrkohlenbergbau und das Versicherungsgesetz fuer Angestellte.) F. Bertrams, Glückauf, 1912, 9, pp. 358-63; 10, pp. 399-404.

Miner's Pension Fund. Proposed Legislation. (Les retraites des Mineurs. Proposition de loi.) Rev. Noire, Vol. 15, 1912, 381, pp. 78-9; 383, pp. 99-100. (National pension fund for miners.)

Workmen's Liability Insurance. C. O. Bartlett, Mines Minerals, Vol. 32, 7, p. 412. (The cost, and who shall pay it—relative dangers of the different industries.)

Utilizing Unmined Coal for the Production of Gas. A. G. Betts, Journal Gas Light, Vol. 118, 2552, pp. 95-6, 5 fig. (The article contains a full description of an American patent taken out in 1909 to utilize coal seams too thin or too poor to be worth working.)

The Valuation of Mineral Properties. T. A. Donahue, Coll. Guard., Vol. 103, 2670, pp. 423-4. (The valuation of deferred production of mineral estates and a consideration of the applicable rate of interest upon which to calculate.)

II—GEOLOGY

The Klip River Coal Field. Natal, S. Afr. Engin., Vol. 17, 1., pp 1-2, 2 profiles. (A general idea of the geological structure of the coal field, principally the results of surface observations.)

III—MINING TECHNOLOGY

A Hydro-Pneumatic Rock Drilling Machine. (En hydropneumatisk Bergborrmaskin.) G. E. Gjuke. Bihanf till Jernkontorets Ann., 1912, 2 pp., 112-23, 4 fig.

IV—WORKING OF MINERALS

The Roden Coal Co's. Plant in Alabama. C. A. Tupper, Coal Age, Vol. 1, 25, pp. 800-3, 3 fig. (A carefully designed and equipped plant in which no expense has been spared to bring the working costs to a minimum.)

The Dewar, Oklahoma, Coal Field. J. A. Garcia, Coal Age, Vol. 1, 28, pp. 898-9, 2 fig. (The Dewar field is an excellent example, on a small scale, of the benefits derived from consolidating the individual operators.)

Engineering Requirements in Bituminous Coal Mining. W. E. Fohl, Proc. Engin. Soc. West Penn., Vol. 27, 9, pp. 503-54, 1 fig. (Deals with engineering difficulties in the mine—mechanical, operative and human.)

Method of Mining Coal. William Griffith, Mines Minerals, Vol. 32, 7, pp. 402-3, 6 ill. (Filling rooms by blasting floor up and roof down to occupy the worked out spaces.)

Mining Methods in Illinois. M. F. Peltier, Coal Age, Vol. 1, 23, pp. 732-5, 2 fig., 1 map. (A general description of one of the most important fields in Illinois.)

The Coal Fields of British Columbia. R. R. Hedley, Can. Min. Jl., Vol. 33, 6, pp. 207-9.

Silesian Mining Methods. B. C. Gullachsen, Coal Age, Vol. 1, 26, pp. 844-5, 7 fig. (In northern Silesia, the coal of the thick seams is developed by narrow stall workings driven in the lower benches of the bed. Final recovery is affected by retreating panel methods, the whole bed being extracted.)

V—BORING, SHAFT SINKING AND TUNNELLING

Recent Practice in Diamond Drilling and Borehole Surveying. J. I. Hoffman, Inst. Min. Metall., Bull. 91, pp. 1-11, 6 fig., 1 pl., 3 folders.

Studies and Experiments on the Freezing Method. (Studien und Versuche über das Gefrierverfahren.) W. Walbrecker, Diss. Lex., 21. Essen Ruhr., W. Girardet, 1912.

The Rogers Drop Shaft, Iron River, Mich. P. B. McDonald, Min. Sci. Press., Vol. 103, 27, pp. 831-3, 9 fig. (Surface equipment and construction of a concrete drop shaft under compressed air to a depth of 140 ft.)

Shaft Bottom at the Arenberg Mine. Mines Minerals, Vol. 32, 7, pp. 413, 1 fig.

Sheet Steel Piling for Sinking Shafts. Coll. Guard., Vol. 103, 2676, pp. 734-5, 4 fig. (The installation at Hatfield Main Colliery is described and illustrated.)

Ferro-Concrete Work at Harrington Collieries. Iron Coal Rev., Vol. 84, 2302, pp. 572-3, 8 fig. (The work includes the creepers at the pit bottom, the cage framing, cages, headgear, slack conveyor, banking house and gantries.)

VI—BLASTING, EXPLOSIVES

Recent Developments in Explosives. A. E. Anderson, Eng. Min. Jl., Vol. 93, 5, pp. 270-3. (The recent development of mining explosives made from nitroglycerine, with or without nitrate of ammonia.)

Electricity in Connection with Explosives. K. Scott, Iron Coal Trades Review, Vol. 84, 2291, pp. 132-4. (Ammonium nitrate the basis of the safest explosives; nitrogen from the atmosphere, dicyandiamide as a reducer of temperature of explosions.)

Queensland Mine Regulations for Explosives. Austral. Min. Stand., Vol. 47, 1218, pp. 242. (The compulsory appointment of a qualified shot-firer with written credentials; detailed instructions as to shot-firing, and the handling and storing of explosives.)

VII—TIMBERING, PACKING, ETC.

Mine Timbering. R. B. Woodworth, Coal Age, Vol. 1, 25, pp. 809-11, 11 fig., 2 tab., 27, pp. 873-5, 3 fig. (The use of steel in the proper forms for certain classes of work, general methods of design, and cost of manufacture and installation.)

VIII—WINDING AND HAULAGE

Electric Haulages in Mines. W. C. Mountain, Iron Coal Trades Rev., Vol. 84, 2296, pp. 334-8, 11 fig. (An explanation of the different types of haulage used underground in collieries, given in a paper read before the N. Eng. Assoc., Min. El. Eng.)

Results of the Prussian Statistics of Winding Ropes for the Year 1910. (Ergebnisse der preussischen Statistiken der Schachtfoerderseile fuer das Jahr, 1910.) Fr. Herbst, Glückauf, 1912, 9, pp. 333-46; 10, pp. 424-7, 41 fig. (Protective effect of greasing and galvanizing. Influence of deflection. Tensile strength; results with strands of triangular section. Coefficient of safety.)

Large Winding Engines for South India. S. Afr. Min. Jl., Vol. 9, 2, pp. 727-8. (Engines to wind from a shaft 3700 ft. deep at 3000 ft. per min., an unbalanced load of 15.5 tons, developing 5,000 h.p.)

The Walker Overwinding-Prevention Gear. J. Paul, Trans. Min. Inst. Scot., Vol. 34, 2, pp. 56-60, 1 fold plate (An apparatus which first sounds an alarm bell and then automatically applies the brake, shuts off steam and centers the reversing gear, as fitted at the Mary Pit of the Lochgelly Iron & Coal Co., Ltd., on the cage winding gear.)

Prevention of Overwinding. Iron Coal Trades Rev., Vol. 84, 2302, pp. 561-4, 8 fig. (A description of the Visor controller and some practical experiences in its working.)

IX—LIGHTING

Portable Electric Lamps for Miners. Coal Age, Vol. 1, 26, pp. 836-7, 3 fig. (Electric lamps, worn by the mine worker, and giving a reliable light continuously for more than 12 hrs., are being introduced in a number of collieries.)

Miners' Safety Lamp Electrically Lighted. J. Prestwich, Iron Coal Trades Rev., Vol. 84, 2296, pp. 351, 3 fig.

The Safety Lamp: Its Use and Abuse. G. H. Winstanley, Min. Engin., Vol. 16, 214, pp. 32-3. (A lecture upon the scientific use of the safety lamp as an instrument for the detection of inflammable gases.)

Electrical Lighting of Mines. W. M. Thornton, Coll. Guard., Vol. 103, 2676, pp. 733-4. (The use and advantages of metallic filament lamps in mine service.)

X—VENTILATION

Overcasts with Light Walls. A. A. Steel, Mines Minerals, Vol. 32, 9, pp. 515-6, 2 fig., 1 tab.

Measuring Low Pressure Air. G. S. Weymouth, Min. Sci. Press., Vol. 104, 16, pp. 562-3, 2 fig. 1 tab. (A method for measuring small quantities of air at low pressure by means of a simple apparatus suitable for actual working conditions.)

XI—MINE GASES, TESTING

Testing for Firedamp and Blackdamp by Means of a Safety Lamp. H. Briggs, Trans. Inst. Min. Engin., Vol. 43, 1, pp. 64-79, 4 fig.

A Carbonic Oxide Detector. (Detektor na kyslicnik uhelnaty.) R. Nowicki, Hor. a hut. list, Vol. 12, 11, p. 161, 1 ill. (A small pocket apparatus with which the presence of carbon monoxide in the air down to 0.1 per cent may be detected, by means of a palladium chloride paper.)

XII—COAL DUST

Some phases of the Coal-Dust Question. W. Galloway, Proc. S. Wales Inst. Eng., Vol. 28, 1, pp. 6-35, 2 fig., 2 plates. (Early experiments and recent continental and American developments.)

Reduction, Control and Collection of Coal Dust in Mines. S. Mavor, Trans. Inst. Min. Eng., Vol. 42-3, pp. 496-556, 2 fig., 2 tab.

The prevention of Coal Dust Explosions. J. Hargar, Iron Coal Trades Rev., Vol. 84, 2296, pp. 332-3. (A discussion of the subject before the Manchester Geol. Min. Soc. mainly as to the advisability of reducing the oxygen in the ventilating air supply.)

Notes on Some Coal Dust Explosion Problems. J. Ashworth, S. Wales Inst. Eng., Vol. 27, 7, pp. 720-32, 1 fig., 4 plates. (Neither a stone-dust nor a watered zone restrains a detonative effect under experiment; there is therefore no known means of controlling the extent of an explosion.)

XIII—EXPLOSIONS

Causes and Prevention of Coal Mine Explosions. E. K. Judd, School Mines Qrtly., Vol. 33, 1, pp. 65-71. (A discussion of the most satisfactory method of robbing coal dust of its dangers.)

Bignall Hill Colliery Explosion. R. A. S. Redmayne, Coll. Guard., Vol. 103, 2679, pp. 881-4, 3 fig. (A report on the gob fire at Bignall Hill presented to the Home Department and dealing with the whole subject of gob fires in mines.)

The Susie, Wyoming, Explosion. C. S. Beach, Coal Age, Vol. 1, 28, pp. 908-9, 1 fig. (The article treats of the cause and effect of the explosion and ascribes the accident to the carelessness of some of the miners.)

Lessons from Recent Mine Disasters. J. A. Holmes, Mines Minerals, Vol. 32, 9, pp. 524-6. (A criticism of the destructive economic conditions which lead to loss of life and waste of resources in the United States.)

Cross Mountain Mine Explosion. Mines Minerals, Vol. 32, 7, pp. 393-7, 1 fig., 4 ill. (The mine, its ventilation plan, the effects of the explosion, and the recovery work.)

XIV—MINE FIRES

The Giroux Mine Fire. H. H. Sanderson, Mines Minerals, Vol. 32, 7, pp. 435-6, 1 fig (Facts in regard to its occurrence and the methods of recovering after the fire.)

Gob fires in the South Yorkshire Coal Fields. W H. Pickering, Min. Eng., Vol. 15, 212, pp. 303-4 (Their causes and remedies; methods of working the seams, gob fires most usual at the edge of shaft pillars, or where wall or timber is left in the goaf.)

Air Mattresses for Confining Mine Fires. C Scholz, Comp.-Air. Mag., Vol. 17, 4, pp 6495-6, 1 fig (A pneumatic curtain is described which is used in the Consolidated Indian coal mines, U. S. A. In some gaseous mines, square air mattresses, blown up by hand air pump, are utilized to make a first stopping of the air circulation; the fans then being reversed the smoke drawn back into the fire which is thereby quenched.)

XV—RESCUE AND AMBULANCE

Accidents in Anthracite Coal Mines F. L. Hoffman, Coal Age, Vol. 1, 29, pp. 940-2, 6 tab. (Tables are given showing the number of persons killed and injured and the nature of the accidents occurring in each inspection district of the Pennsylvania anthracite region from 1906-10.)

A Motor Car for Mine Rescue Work. F. C. Perkins, Mines Minerals, Vo.l 32, 9, p. 517, 1 fig.

XVI—DRAINAGE, PUMPING, ETC.

Mine Drainage. (Bergmaennische Wasserwirtschaft.) Kegel, 8vo, 9, 211 pp., 205 ill. Halle, W. Knapp, 1912.

Unwatering Tresavean Mine, Cornwall. C. Barckenbury, Mines Minerals, Vol. 32, 9, pp. 566-70, 4 fig. (The unwatering, after 150 years' abandonment, has been successfully accomplished by means of electric high-lift turbine pumps, down to below the 248 fathom level beneath adit.)

Water Purification for Collieries. Coal Age, Vol. 1, 25, pp. 804-6, 6 fig. (The article treats of water purifying processes and apparatus, necessitated by the increasing demand for colliery bathing facilities and larger central station power plants.)

XVII—PREPARATION

Coal Washing at Lahousoge. D. A. Willey, Mines Minerals, Vol. 32, 7, pp. 391-2, 1 ill.

XVIII—COKE OVENS

Device for Extinguishing, Drying and Storing Coke. (Dispositif pour l'extinction, le séchage, et l'emmagasinage du coke de la Société d'Eclairage, Chauffage et Force Motrice.) Rev. Noire., Vol. 15, 1912, 383, p. 102, 2 fig.

Coke Oven Tars of the United States. P. Hubbard, Chem. Engin., Vol. 15, 3, pp. 92-6, 3 tab. (An analytical study of the properties of coke oven tars of the United States; a list of analysis is given of the crude tar production of 26 manufacturers.)

The Jamison Coke Plants, Greensburg. R. D. Hall, Coal Age, Vol. 1, 29, pp. 936-9, 6 fig., 1 tab. (The plants described make only 72 and 96 hour coke. The ovens supply waste gas to two boiler plants. The coke made is superior to the ordinary beehive coke, being free from black butts and a trifle lower in sulphur.)

Extensive Use of Coke Oven Gas. C. A. Tupper, Coal Age, Vol. 1, 26, pp. 832-5, 5 fig. (The article is intended to give some idea of the extent to which coke oven gas is used in combustion engines for the generation of power, and the great number of plants so operated in Europe.)

Byproduct Coke Ovens in America. F. E. Lucas, Mines Minerals, Vol. 32, 9, pp. 530-1.

XIX—FUEL TESTING

Mount Mulligan Coal Deposits, Queensland, for Coke Making and Coal Supplies. C. F. V. Jackson, Austral. Min. Stand., Vol. 47, 1211, pp. 76-7. (The coke tests were carried out in a small beehive oven and the boiler tests in a water tube boiler.)

Experiments on the Conservation of Coal by Storing under Water. (Liegen Erfahrungen oder Versuchsergebnisse über Konservierung von Kohlen under Wasser vor.) Z. Dampfkessel-Betr., 1912, 5, pp. 49-53, 3 fig., 1 tab. (By storing in the open air for 12 months there resulted a small reduction of heating value. By storing under water there is no loss of heating value, nor is there any change in the quality of coal.)

Fuels, their Testing and Combustion. (Unsere Brennmaterialien, ihre Untersuchung und ihre Verbrennung.) H. Leefelder. 8vo., 3, 81 pp., 9 ill. (Techn. Volksbuecherei, Vol. 6), Berlin, Maritima, 1912.

Spontaneous Combustion of Coal. G. C. Porter and F. R. Ovitz, Gas World, Vol. 56, 1435, pp. 12-3. (Recommendations as to the storage of coal; submergence storage is an absolute preventive but entails firing wet coal.)

The Carbon Dioxide Recorder as a Factor in Fuel Economy. E. A. Uehling, Jl. Ind. Engin. Chem., Vol. 4, 2 pp., 123-4, 4 fig.

The Microscopical Examination of Coal. J. Lomax, Coll. Guard., Vol 103, 2677, pp 787-8. (A reply to the points raised in the discussion of a paper read upon this subject.)

Calculation of Heat Value of Coal. O L. Kowalke, Power, Vol. 35, 16, pp. 558 9, 2 fig. (A simple formula and chart are given for figuring the heat value from the proximate analysis.)

XX—STEAM ENGINES AND BOILERS

Locomotive Boilers at Collieries Coll. Guard., Vol. 103, 2676 pp 731 2, 6 fig (An explanation is offered of how some of the more common defects occur and means by which danger may be averted.)

XXI—ELECTRICITY

The New Rules on Installation and Use of Electricity in Mines. Coll Guard, Vol 103 2670, pp. 431-2.

Mining Electrical Rules. W. C. Mountain, Iron Coal Trades Rev, Vol. 84, 2289, pp. 60-1 (The concentric system, leakage indication, efficient insulation.)

Electric Power in Southeast Kent. El. Rev., Vol 70, 1786, pp. 261-6, 14 fig (The Tilmanstone power house and colliery equipment at the adjacent mines.)

Central Station Generation of Power at the Central Indiana Coal Fields. J. V Hunter, Proc. Am. Inst. El. Eng., Vol. 31, 3, pp. 277-82, 2 tab. (A discussion as to whether the conclusions derived from Indiana are applicable to Pennsylvania and other coal fields.)

Central Station Power in Coal Mines. W. H. Thomas, Proc. Am. Inst. El. Eng., Vol. 31, 3, pp. 245-58, 5 fig. (Discusses the advancing usefulness of electric power in mines with especial reference to the use of straight alternating current hoist motors up to 500 hp. capacity.)

Central Station for Colliery Service. E. B. Wagner, Coal Age., Vol. 1, 26, pp. 838-9, 5 fig. (The equipment of a small central station is described.)

Power Generation and Distribution in the Pit "von der Heydt." (Krafterzeugung u. Verteilung auf dem Steinkohlenbergwerk "von der Heydt.") El Kraftbetr., 1912, 8, pp. 153-6, 2 ill. (Data of the gas-engine power plant, the electric switch gear and distribution.)

Remote Control of Electrical Apparatus in Mines. Iron-Coal Trades Rev., Vol. 84, 2302, pp. 566-7, 2 fig.

Motor Starters for Mining Work. A. P. Drake, Iron Coal Trades Rev., Vol. 84, 2302, pp. 572-4, 2394, pp. 638-40, 2 fig. (A discussion upon the selection of suitable starting switches.)

Fault Location on Mining Cables. G. B. Burrows, Iron Coal Trades Rev., Vol. 84, 2305, pp. 695-6, 9 fig.

XXII—SURFACE TRANSPORTATION

Peckfield Colliery. Iron Coal Trades Rev., Vol. 84, 2296, pp 321-2, 1 fig. (A new installation of surface plant and relayout of sidings; the screens are designed to deal with 3000 tons per 10-hr. day.)

The Consolidated Fuel Co., Utah. B. Shubart, Coal Age, Vol. 1, 29, pp. 944-5, 3 fig. (The article describes a characteristic mountain coal operation with some of the difficulties encountered.)

Coal Bunkers of Reinforced Concrete. (Kohlenbunker aus Eisenbeton.) Kupfer, Kohle Erz, 1912, 10, pp. 223-6. (Advantages of reinforced concrete bunkers.)

Double Tipple for Colonial Coal Co. W. T. Griffith, Coal Age, Vol. 1, 28, pp. 906-7, 3 fig. (The construction of a double tipple to meet special conditions at Prestonsburg, Ky. The tipple and the local power plant are described.)

XXIII—SANITATION, DISEASES

Miner's Phthisis. Min. Jl., Vol. 96, 3991, pp. 159-62. (A complaint mainly due to modern conditions of operating; the neglect of preventive regulations; state and private control should co-operate.)

Miners Nystagmus. J. Court, Optician, Vol. 43, p. 1099, p. 87-8. (Conclusions from researches conducted over a number of coal fields and extended to metalliferous mines, on the connection between nystagmus and the bad light given by ordinary safety lamps and individual predisposition.)

Housing of Scottish Miners. Coal Age, Vol. 1, 28, pp. 921-2, 3 fig. (The average miner's house in Scotland is more substantial and better equipped than in the United States. It supplies, however, quarters too narrow to suit the average American working-man and the ventilation is inadequate.)

Disinfecting Miners' Dwellings. W. H. Ross and R. C. Benner, Min. Sci. Press., Vol. 103, 27, pp. 829-30. (The principal germ-destroying agents and methods of use.)

Miners' Baths. H. F. Bulman and W. B. Wilson, Trans. Inst. Min. Engin., Vol. 43, 1, pp. 92-110, 19 fig. (Data on the question gathered from Westphalia, Belgium, and the North of France.)

Miners' Baths and Bath Houses. G. B. Walker, Engineering Mag., Vol. 42, 3, pp. 371-85, ill. (Recent British and continental practice illustrated,)

Throwing The Searchlight On Advertising

Little Talks on a Big Subject for Coal Age Readers

By the Ad. Editor

The other day a man came into our office and wanted to put an advertisement in the paper. He had a device for coal mines and wanted to introduce it to you readers through these columns.

* * *

In the course of the conversation we asked him if his product had been tested and *proved*.

He replied that the tests were in progress but that the results were not yet certain.

What did we do?

Simply told him not to risk his money in *advertising* the article until he *knew* and could *prove* that it would do the work he expected it to—

And, on thinking it over, he thanked us and went away. He'll come in again one of these days (if his tests come out right) and when he starts advertising he'll be *investing* money instead of *risking* it.

* * *

Now what does that little experience mean to you?

Simply that *we* knew that this man was starting wrong —that it would be utter folly to *advertise* an article before he was *sure* it had merit.

Because there isn't a chance on earth for a man to make money advertising a product that won't make good every claim the ad makes.

Not long ago a large concern lost several hundred thousand dollars advertising a liniment that proved to have undesirable features—

And another well-known concern lost many thousands by advertising, at a low cost, a machine that buyers found wouldn't last.

They redeemed every machine at the price paid for it—and were out all the thousands they had spent on advertising. Besides their reputation suffered more than money could repay.

The point is, advertising *must* be backed up by merit in the article advertised or the advertiser loses—loses heavily and loses alone.

Or, from *your* viewpoint, *if* an article is continuously advertised in your paper you can bet your last dollar that that article has all the merit and value claimed for it—

And such an article is worth your serious consideration and investigation.

* * *

What is it that has made the names "Tiffany" on jewelry, "Victor" on phonographs and "Elgin" on watches valuable?

Just advertising backed up by guaranteed, unfailing merit and quality in the goods so marked.

Isn't it pretty clear that, in advertising, "honesty is the *only* policy"—

And that buying advertised goods is the *safe* policy for you?

Alphabetical Index to Advertisers

Classified Index to Articles Advertised

¶ Are you getting the full benefit out of these advertising pages?
¶ Look them over carefully and you will learn things that will make you worth more to yourself.
¶ Nearly every advertisement contains something that *you* ought to know.

POSITIONS VACANT

Advertisements under this heading 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

Mine electrician to take care of the underground work in electrically operated mine; must be able to repair and keep in running condition and be thoroughly familiar with locomotives, electrical pumps, electrical punchers and shortwall machines; state age, experience and references, also salary desired. Address Box 42, Coal Age. June 15.

Wanted—A technically trained engineer to serve as Associate Editor on Coal Age; a mechanical man with experience in the design and construction of breakers, tipples, power plants, etc., is especially desired; unusual opportunity for right party to investigate new installations and to study most recent practice. Address "Editor," Coal Age. June 8.

Wanted for mine inspector; man with extended experience in bituminous mines; must be capable of acting in an advisory capacity, being familiar with modern mining methods and show records of positions successfully filled as mine foreman, etc.; excellent opportunity for right man. Reply, giving detailed experience, age, nationality, positions held with salary obtained and references, to Box 36, Coal Age. June 8.

SITUATIONS WANTED

Advertisements under this head 25 cents for 25 words or less. Additional words, two cents a word. Cash or stamps must accompany order.

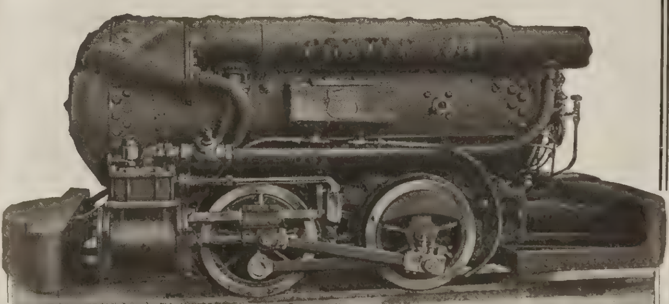
Wanted—Position as superintendent; all I ask is that you investigate; correspondence absolutely confidential and immediately returned. Address Box 43, Coal Age. June 8.

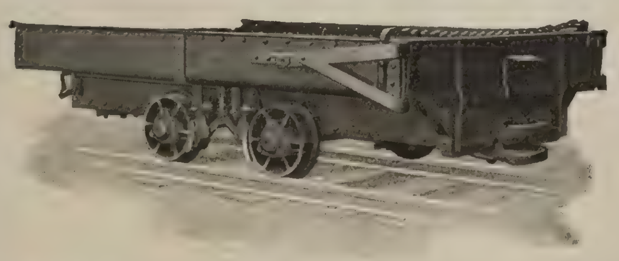
Mining engineer, seven years' experience on mine, land and railroad surveys and mining construction, now engineering teacher, desires summer employment. Address Box 39, Coal Age. June 15.

Wanted—To operate small mine on contract, decrease your output expense, and produce coal from your mines cheaper than it costs you; now operating under contract a shaft mine for leading mine corporation of Pennsylvania; A-1 references. Address "J. F. C.," care Coal Age. June 8.

Wanted—To hear from companies needing first-class electrician with recognized knowledge and ability and mechanic with executive ability; expert on armatures, winding, building, power plants, construction, remodeling, mine locomotives, coal cutters, fans, pumps; best credentials as to integrity and ability. Address Box 41, Coal Age. June 8.

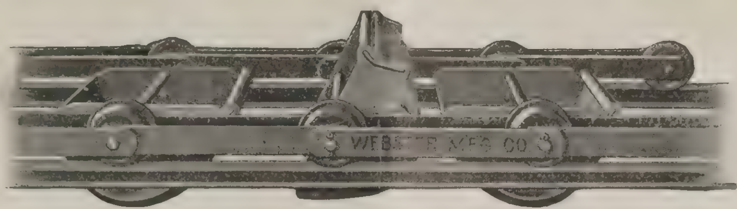
Position as superintendent by married man, 39 years old; college and university graduate; sixteen years' practical experience, mostly inside coal mines Pittsburg district, as miner, roadman, driver, weighmaster, surveyor, fireboss, assistant mine foreman, mine foreman and superintendent; good health, good habits and best of references; salary $250. Address Box 32, care Coal Age. June 8.





A Small Improvement That Does Big Things Has Been Perfected In The

Perkins Carrier

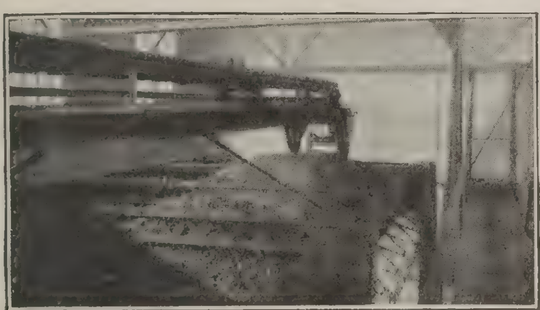


Will handle Coal, Ore, Ashes, Gravel, Sand, Cement, Etc., Etc.

It is the most important improvement made in many years in a pivoted bucket carrier. It has overcome the last difficulty in handling material with this class of conveyors—namely, the problem of spillage.

Pivoted Bucket Carriers

oftimes offer the most effective way of handling; but the expense of labor in gathering spillage has always increased the cost of operation and been a source of constant trouble. The **Perkins Carrier** reduces the spillage to a negligible minimum, and all but eliminates the expense of picking up the droppings.



Perkins Carrier Handling Coal.

It is perfectly non-spilling in loading, yet without overlapping lips or anything of the sort to require special provisions for their passage by each other at corners of the quadrangle. The swinging pipe roller at one lip of each bucket does it.

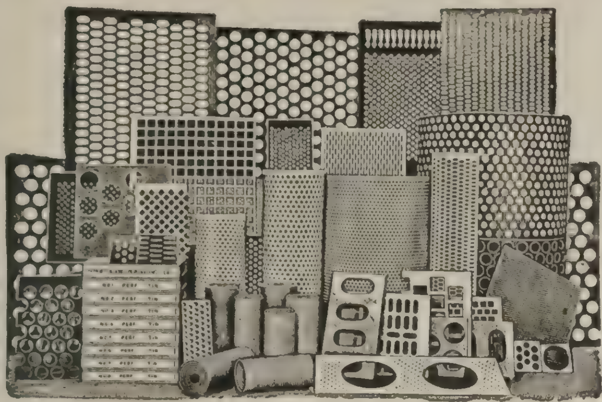
This is just one of the improved features of the Perkins. The others are worth learning. For instance, we can show you how it has effected big savings for many present users. We can tell you how it will prove of practical and economical value in your own work.

Our Magazine, "*Webster Method*," is filled with valuable suggestions on questions of Economical Handling. If you do not get it, let us know.

THE WEBSTER M'F'G COMPANY, TIFFIN, OHIO

New York	Pittsburgh	Chicago
88-90 Reade Street	Dempcy-Degener Co.	815-817 Fisher Bldg.

3



Perforated Steel Screen Plates

For Coal and Coke, Crushed Stone, Phosphate Rock, Gravel, Sand, etc.

¶ Cylindrical Screen sections rolled to diameter lap or butt joints, and fastened with clips, bolted or riveted—segments for Taper Screens rolled to diameter with bolt holes in margins.

¶ Flat screen plates of any dimensions to 10x20 feet to one inch thick for heavy work.

¶ Standard sizes of Round, Oblong and Square holes—special sizes made to suit.

¶ Manganese Bronze or Monel Metal screens for acidulated or sulphurous mine waters.

OUR sizes are standard centers (distance apart) but we can give you closer or wider spacing if required—in other words *you get what you want.*

The screens are made with care, exact to details of size, thickness and dimensions—in point of material and workmanship the best of their kind

Please send detail specifications with your order or inquiry.

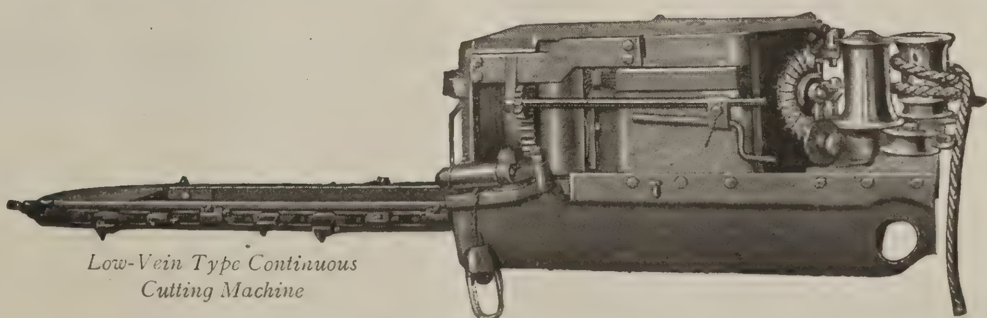
THE HARRINGTON & KING PERFORATING CO.

628 North Union Street, CHICAGO, ILL.

New York Office: 114 Liberty Street

You've Got To Consider Three Things In Selecting

Coal Mining Machines



Low-Vein Type Continuous Cutting Machine

First you've got to consider the machine itself, its ability to mine large tonnage and its cost of upkeep. Then you've got to consider it in connection with the machine runner, whether its operation is easy enough and its construction simple enough to enable him to do the most and the best work.

Finally you've got to consider whether the quality of your coal is improved for the market and whether the Machine can be adapted to your Mine conditions.

Mining Machines made by the Morgan-Gardner Electric Company are the most productive and the most popular because they meet these three considerations most satisfactorily.

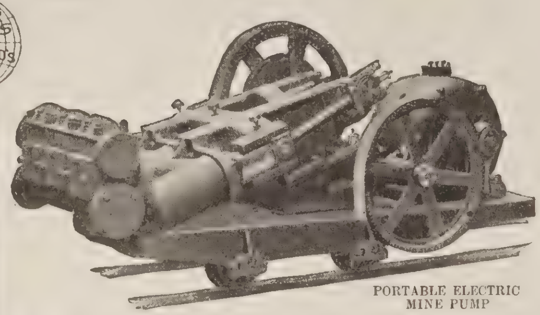
Circular SA, descriptive of this machine, sent on request. Also Catalogs of other mining machines and locomotives. Write us.

Morgan-Gardner Electric Company

Main Office and Works, 27th Street and Shields Avenue, CHICAGO, U. S. A.

DEMING MINE PUMPS

Read below what Mr. Holsing, Supt. of a large Coal Company in Virginia, says about Deming Pumps.



PORTABLE ELECTRIC MINE PUMP

"The writer has been using your pumps for a number of years and for efficiency, economy, and rough usage they cannot be excelled. The mines we have used them in are not making very strong sulphur water, but we have pumped gritty and dirty mine water at one mine continuously for two years *without one cent for repair parts*."

IF YOU WANT THAT KIND OF PUMPING SERVICE INVESTIGATE THE DEMING PUMP THOROUGHLY

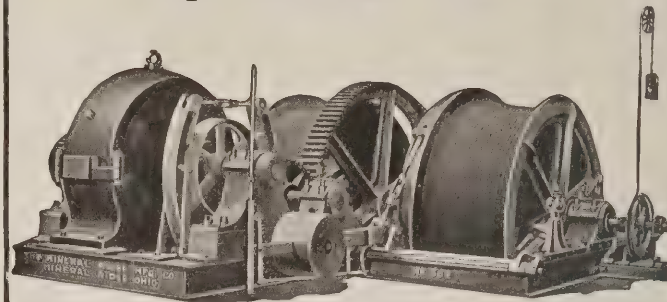
Name on Application.

THE DEMING COMPANY,
Salem, Ohio.

HAND AND POWER PUMPS FOR ALL USES

Henion & Hubbell, Chicago. Harris Pump & Supply Co., Pittsburg. Hendrie & Bolthoff Mfg. & Supply Co., Denver, Colo.

Designed to Cut Mine Operating Costs



Mineral Ridge Mine Hoist

Designed by expert mining Engineers—executed by equally expert machinists.

Under any mining conditions, Mineral Ridge Hoists are bound to give perfect and lasting satisfaction.

Made for either steam or electricity. May be operated automatically or from a distance but—at all times, under absolute control.

Operating costs are low—the construction simple—and their dependability unquestionable.

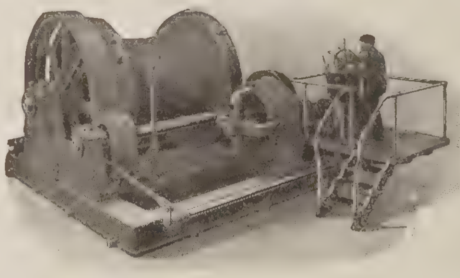
Full particulars if you'll write.

The Mineral Ridge Mfg. Co.
Mineral Ridge, Ohio.

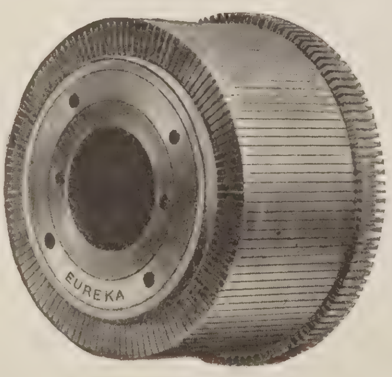
Vulcan Hoists

Are made for every condition of mine hoisting. We have the facilities, the capacity, and the organization for building hoists of any size and to meet any practical condition.

Our illustrated catalog describes complete line. Write for a copy.



VULCAN IRON WORKS
WILKES-BARRE, PA.

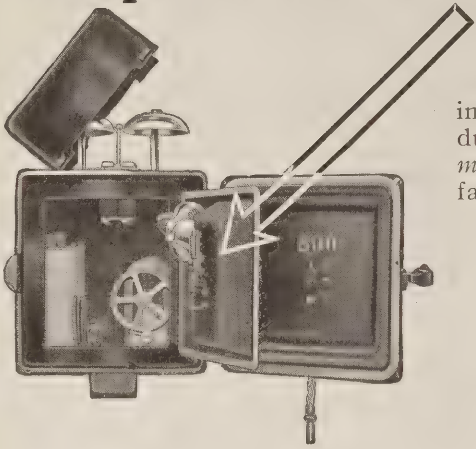


NOT only Commutators, Line Material and Bearings, but remember, we make all kinds of Copper, Bronze and Brass Castings. Bronze Jackets cast on Pump Plungers.

Give us a trial.

THE EUREKA COMPANY
North East, Pa.

Made *For* Mine Conditions—Not Merely Adapted *To* Them



MINE-A-PHONE

Look where the arrow points—that inner door—perfectly insulating the mechanical chamber from any possible damp or dust—no chance for the mechanism to be affected. Made to *meet* mine conditions where a telephone *adapted* to them would fail hopelessly.

See how simple the MINE-A-PHONE is—see how easily accessible—how little chance for getting out of order—how *fool-proof*.

And the whole fabric of MINE-A-PHONE superiority is woven around that one point—*designed and made* to meet the hard conditions of mine use.

There are twenty-two exclusive features in every MINE-A-PHONE—every one of them a convincing argument why you need to have a MINE-A-PHONE help in your mine.

We've a Bulletin—No. 2600—telling all about the MINE-A-PHONE way. It's not prosey—quite the contrary. You'll be interested. *Send for it today.*

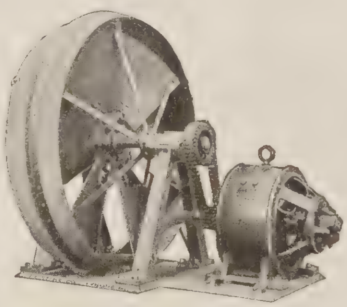
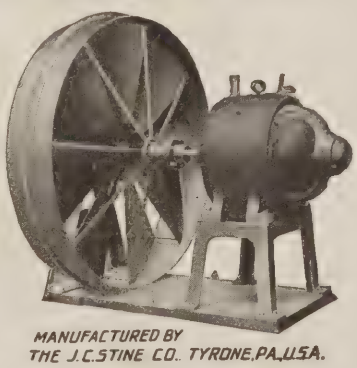
J. C. STINE Patented Disc Fans



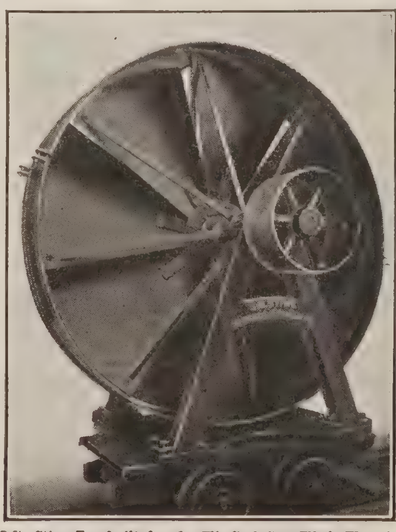
are made by people who know how. Actual tests show 85% mechanical efficiency, the highest efficiency of any fan made regardless of cost. Being equipped with specially designed self-starting, interpoled motor with fan and motor on the same bed-plate no attention is required beyond an occasional oiling. Ten sizes—3 ft. to 8 ft. in diam. Capacities 20,000 to 120,000 cu. ft. per minute. Prices surprisingly low. We guarantee highest efficiency, lowest upkeep and greatest durability.



The J. C. Stine Company, Tyrone, Penna.

Does Your Mine Need Air?

The Stine Disc Fan has been the standard of excellence for 35 years. Write for references in your vicinity.



8 ft. Stine Fan built for the Elk Coal Co., Elkol, Wyoming

One Company alone has 60 of our Disc Fans. Proof of excellent satisfaction.

A Letter From A User

LINCOLN COAL CO., LESSEES ELK COAL CO.

S. B. Stine, Elkol, Wyo.

Dear Sir:—In regard to the 8 ft. fan furnished this company by you some few years ago, can say that it has given entire satisfaction and is running as smoothly today as at the time it was installed. **It is the one piece of machinery around the place that has required no repairs.**

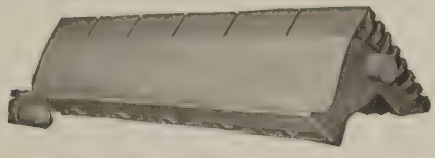
Yours very truly,
Walter B. Harris, Supt. (Signed)
Lincoln Coal Co. Lessees.

Ask for Bulletin 59.

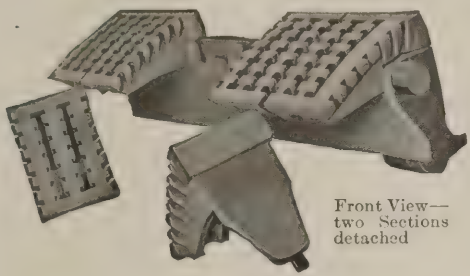
The service of our Engineering Dept. is at your service. Write or wire us.

S. B. Stine, Osceola Mills, Pa.

Designer and Builder of Complete Mining Equipment.

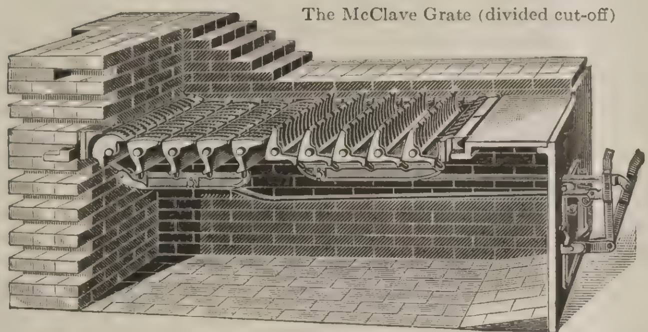


Back View of McClave Removable Sectional-Top Grate Bar No. 2.



Front View—two Sections detached

The McClave Grate (divided cut-off)



Better Grate Bars

The McClave Grate No. 2

The body portion of this bar is *below* the level of the fire (as shown), absolutely protected from heat action by the tops. These tops are removable in sections, fitting down firmly with a shank and socket arrangement.

In case of breakage or burning, repair costs are transferred from that for a whole bar, to that for a single section. Any section can be easily lifted out and a new one placed, while fire is burning.

The body section is *trussed* in design, stronger than any one-piece bar.

McClave Grates with Argand Blowers

Provide A Complete Steam-Making System For Cheap Fuels.

The cheaper fuels such as anthracite birdseye, buckwheat slack, rice, etc., are all used to excellent advantage.

No. 3 Buckwheat, for instance, has been burned with results practically identical with those with first grade coal, on regular grates.

Ask for information about our new **Sectional Top Dumping Grate No. 4 A for small anthracites.**

Other details gladly furnished.
Catalog H on request.

McClave-Brooks Company

Scranton, Pa.

Clean Your Fires With The Door Shut

The "Ajax" Self-Cleaning Rocking Grate does away entirely with the cleaning of fires by means of pokers and slice bars. The fireman has absolute control at all times. The illustration shows the manner of attaching double shaking levers to the boilers front and covers a two unit construction. *No change in boiler front is required except to cut a slot for the shaking lever to pass through.*

The AJAX

The grate stands on its own legs. We guarantee that the Ajax will give a clean fire and a full and regular supply of oxygen. 65 per cent air space is an "Ajax" feature. Why not take advantage of our 60 days' trial offer. We stand the risk, shoulder the expense, and take the grates back if they fail to satisfy Where others *claim* we make good. Write for details.
